ACKNOWLEDGEMENT

Sincere thanks and appreciation for
technical assistance by Mrs. Barbara Wall
in the preparation of this Manual.

FOREWORD

Physicians as a whole, and too many surgeons, are inadequately informed concerning the prognosis of various types of malignant tumors. Some tumors respond very satisfactorily to correct therapy, whereas a few are associated with a very low 5-year survival rate in spite of the proper application of the optimum methods of therapy known today. The physician should be correctly informed concerning the probability of eradication of the disease following proper therapy, because the patient, or at least the patient's relatives, should be informed of the expected result.

The methods used in reporting cancer end results have been so varied that it is often impossible for even the most discriminative to compare statistics of articles dealing with the same disease. In this Manual the author offers a uniform method of reporting, which should obviate some of this difficulty. He also advocates a uniform classification, which should help to further simplify the process of end result reporting.

The Manual provides a summary of his review of a great number of publications dealing with results and prognosis. These references are listed after each tumor considered, and thus allows the reader to refer to the various publications for more detailed information. Since the material was obtained from articles published between 1953 through 1957, the data can be considered up to date.

This Manual should prove to be of inestimable value for the medical student, busy practitioner, and teaching staffs, and is to be recommended for general use.

Warren H. Cole

Warren H. Cole, M.D.

PREFACE

Only by utilizing the absolute survival rate is it possible to compare statistics from various institutions on an equal basis. The results of figures reported in this manner, of course, are not as good as when there is some degree of selection. On page 6, for example, the absolute 5-year survival rate is listed in one column. Opposite is the 5-year survival rate for Stage I and/or Stage II lesions. The figures for the earlier lesions present a much more optimistic survival picture and emphasize the importance of early diagnosis and treatment.

The figures used in this Manual were calculated from material appearing in the current literature in the years 1953 through 1957. It may be argued that this doesn't represent the true prognosis of cancer, since the majority of cancer cases are not reported in the literature and the reports are usually presented by the larger institutions. All reported series of cases in this period of time were included and large numbers of cases are included for each site, so that the prognosis figures as determined in this manner are as true as it is possible to calculate. Only the more common cancer sites are included in this Manual.

It is hoped that the prognosis material included, the staging advocated, and the bibliography included for each area, will make this a valuable addition to the students' and clinicians' library.

A.G.J.

GENERAL INFORMATION

PART I

A. Purpose of Reporting End Results

The best yardstick available for determining the efficiency of a given mode of cancer therapy is the percentage of patients kept alive by that particular therapy. A uniform method of tabulation of cancer therapy results must be established for both individual physicians, the smaller hospitals and clinics, and research and teaching institutions, in order that valid comparisons and evaluations can be made by the medical profession.

The task of framing a standard system for cancer staging and end results reporting is a prodigious one. The staging in this Manual is a ready reference for students and physicians and emphasizes the necessity for uniform clinical stage classification and end result reporting. This classification is simplified and is not intended as a definitive clinical classification for the more elaborate study of cancer at specific sites.

At the present there are several important committees at work on clinical classification for end result reporting. Among these are the Committee on Clinical Staging and Applied Statistics of the International Union Against Cancer, The American Joint Committee for Clinical Staging and End Result Reporting, and committees representing various subspecialty groups.

The American Joint Committee consists of representatives from the American College of Surgeons, the American College of Radiology, The College of American Pathologists, The American College of Physicians, The American Cancer Society and the National Cancer Institute. There are five subcommittees of this group at work on the various cancer site classifications.

The American Joint Committee is making every effort to cooperate with the Clinical Classification Committee of the International Union Against Cancer and to use the basic principles of classification adopted by that committee.

The purpose of this Manual is threefold. First, a simple but concise and practical table for the recording of end results is presented. This method has been consistently utilized in this Manual for the reporting of end results for all organs of the body. Although minor flaws were encountered, such as insufficient statistical material for reporting in each category, it is felt that, of far greater importance, this table offers to the physician a complete and uniform method that can be simply applied to all neoplastic diseases with particular regard to treatment, stage of disease, and pathology. It must be kept in mind that a prime difficulty in collecting the data herein reported was the adaption of others' figures to this table. In no instance, when a case was questionable for a particular category, was it included. With the reporting of statistics specifically for this table, a completeness of each category will rapidly occur, and the system will become even more practical and valid for comparisons. This method of presentation may be criticized by some as being too general, too nonspecific, or offering too many variable factors. However, if examined closely, it can be seen that the basic categories used can easily be more technically subdivided or expanded to give as specific information as is desired (for example: Topic: Surgery and Radiation Therapy could be further outlined as to exact surgery and type and dosage of radiation). In addition, cross-categories can be established after completion of the basic outline (such as: cases treated by Surgery alone in Stage I, II, III, and IV of disease, etc.).

Second in purpose, a method of staging of neoplastic diseases for all organs is presented. When comparing modes of therapy and determining prognosis, the clinical stage or description of the cancer must be considered and compared with cases of disease of similar extent. Again, striving for simplicity and uniformity, the League of Nations staging for cancer of the cervix was used as a model, and, as much as possible, adapted to each organ in the following manner:

Stage I - disease which is limited to the organ in which it originated.

Stage II - disease which is just locally outside of the confines of the primary organ with no other organ or lymph node metastasis.

Stage III - disease which has metastasized to the regional lymph nodes.

Stage IV - disease which has metastasized to distant lymph nodes and/or distant organs.

Third in purpose, this group of statistics is presented as a reference for the medical student, interne, resident and clinician. It is hoped that this Manual will serve as an encyclopedia of cancer end results and a bibliography for all recent cancer prognosis literature.

New material will be added to this Manual at regular intervals for future editions. It is desired that material be submitted to the author by an individual or institution for inclusion, but it is requested that the presentation of data comply with that form presented herein.

B. Mechanics of Manual

The material included in the Manual was obtained from current medical literature from the period of 1953 through 1957. The following journals were reviewed regularly: American Journal of Surgery; Surgery; Surgery, Gynecology and Obstetrics; Radiology; American Journal of Roentgenology; Radium Therapy and Nuclear Medicine; Annals of Surgery; Archives of Surgery; and Cancer. In addition, all issues of Excerpta Medica, volume Cancer, were reviewed, and the original articles presenting end results were utilized. Any reported series of cases presenting sufficient statistics for usage were recorded regardless of author, size or location of hospital or clinic, or method of therapy.

On page 5 is a presentation of all lesions with their absolute 5-year survival rates. Also presented is a column of survival rates for lesions that are localized enough to be resected or early enough to be classified as Stage I or II. The prognosis, of course, is better in the earlier lesions. This provides the reader with a rapid comparison of the survival in all lesions. This is followed by an individual section for each lesion with specific information. The total number of cases which were reviewed for each lesion is listed on the heading of every page. An identical form of presentation was followed for all sections as below:

| | <u>No.</u> <u>cases</u> | <u>% 5-yr.</u> <u>surv.</u> | <u>No.</u> <u>cases</u> | <u>% 10-yr.</u> <u>surv.</u> |

| Stage IV | " | " | " | " |
| Histologic Type: Type 1 | " | " | " | " |
| Type 2 | " | " | " | " |
| Bibliography | | | | |

For the sake of clarity, the terms used should be defined at this time.

5-and 10-Year Survival - the percentage of those patients surviving this given length of time after initial treatment with or without disease. The term "survival rate" was used in preference to the "cure rate". The latter may be somewhat more expressive of the result of treatment; however, there is wide variation in the methods of follow-up from letter questionnaires to careful physician examination, making the definition of "cure" variable. It is felt that "survival rate" provided a more reliable index for comparison.

Absolute Survival Rate - the percentage of patients that survive a given time when all patients seen with disease are considered with no exceptions; that is, all patients admitted or seen in consultation whether or not they receive treatment.

Determinate Survival Rate - the percentage of patients that survive a given time when a selected group of patients are considered. Those patients which are indeterminate or not considered in calculating the determinate rate are only, (1) those lost to follow-up; (2) those seen in consultation only, and, (3) those dying of other cause without neoplastic disease.

Surgery - those cases in which the primary and only treatment was surgical.

Radiation Therapy - those cases in which the primary and only therapy was radiological.

Surgery and Radiation Therapy - those cases in which both surgery and radiation were used regardless of which was the primary mode of therapy.
