## JOB 1: MARINE ANGLER SURVEY <br> PART 1: MARINE RECREATIONAL FISHERY STATISTICS SURVEY

## GOAL

To provide long term monitoring of marine recreational fishing activity including angler participation and catch statistics in a manner that is comparable to other Atlantic coastal states.

## OBJECTIVES

Provide estimates of:

1) Number of marine anglers in Connecticut each year.
2) Total effort (trips) expended by anglers in Connecticut each year.
3) Total catch (numbers of fish kept and released fish) and harvest (numbers and the weight of kept fish) of the most commonly sought species: bluefish, scup, winter flounder, summer flounder, tautog, and striped bass.
4) Length-frequency of harvested bluefish, scup, winter flounder, summer flounder, tautog, and striped bass.

## INTRODUCTION

The Connecticut Department of Energy and Environmental Protection (DEEP), Bureau of Natural Resources, Marine Fisheries Division, has been collecting marine recreational fisheries information along the Connecticut coastline since 1979. However, in order to improve state-wide marine fisheries statistics and become more consistent with other states, Connecticut joined with the National Marine Fisheries Service (NMFS) Marine Recreational Fishery Statistics Survey (MRFSS) in July, 1987. Before Connecticut's involvement in the MRFSS, data collection was conducted by NMFS's contractor just as in other states where state agencies do not participate in the program. The MRFSS has undergone a series of procedural changes over recent years as an outcome of the National Research Council (NRC) independent review and findings in regards to the MRFSS and potential bias. As a result, a new survey was developed and initiated under the Marine Recreational Information Program or MRIP. A critical procedural change in the sampling design of MRIP was the implementation of twenty-four hour per day sampling in the Access Point Angler Intercept Survey (APAIS). Prior to 2013, APAIS sampling took place during daytime peak angling activity times under MRFSS procedures. In addition, MRIP night sampling requires two persons per assignment as a safety precaution. Under these new MRIP guidelines, this meant DEEP would have to possibly double or triple its current resources in order to participate. Finally, insuring personnel safety during night time assignments was an issue of special concern. For those primary reasons, the DEEP decided to
forego MRIP participation in 2013. NMFS' contractor would be responsible for conducting the MRIP APAIS in Connecticut on an annual basis.

## METHODS

In 2013, the DEEP employed a voluntary daily angler catch card program designed to collect fishing trip and catch information including length measurements on harvested and released (discards) fish from marine recreational anglers. Collecting length measurement data especially on discarded fish is extremely difficult to obtain through traditional access point angler intercept surveys (i.e. MRIP). In past years, utilizing volunteer anglers to report their fishing trip information through a volunteer logbook survey (i.e. Connecticut Volunteer Angler Survey program (VAS)) has been very successful. Using the VAS program as a template, two types of volunteer angler catch cards were developed. One type was for distribution by DEEP staff (Connecticut Fishing Quality Evaluation (Individual Fisherman Card - IFC)) and the second, Connecticut Volunteer Angler Survey (Individual Survey Card - ISC), by bait and tackle shop personnel for tracking purposes (see Appendix 1.1 - 1.2). Bait and tackle shops were enlisted to distribute catch cards to their patrons. Anglers were recruited to voluntarily report their fishing trip information and collect length measurements on fish caught including discards. Each participating angler was provided a waterproof daily catch card, pencil, and measuring tape and verbal instructions were given by DEEP staff. Anglers were encouraged to drop off the post marked catch card in the mail upon trip completion or at designated drop-off-boxes installed at these fishing sites. Questions concerning the survey could be queried by contacting the DEEP Marine Headquarters office.

All fishing modes were included in the survey (Shore, Enhanced Opportunity Shore Fishing Access Sites (EOS), Private Boat, Charter Boat, and Headboat). Special emphasis was directed toward gathering angler fishing trip information from EOS areas and the Private Boat Mode (PBM). EOS areas are unique designated fishing locations where regulations for particular species (summer flounder and scup) are less restrictive than other fishing modes. Typically, shore-based fishing sites are less productive than other fishing modes in Connecticut. Relaxing fishery regulations at EOS areas were meant to increase the chances of an angler bringing home fish for consumption purposes. In addition to EOS areas, PBM sites with high activity (primarily state boat launching facilities) were chosen in order to maximize card distribution. Vessel registrations were also collected from participating anglers in the PBM.

## RESULTS AND DISCUSSION

Survey volunteers provided important data concerning individual angler trip, catch by species, and length measurements on both kept and discarded fish. As described previously, the catch card is designed to collect catch and fish length information on fish caught for an individual angler fishing day/trip by fishing mode. Anglers were asked to fill out the following (data fields):

- Conservation identification number (fishing license number)
- Primary target species
- Secondary target species
- Total hours spent fishing
- Fishing area (Connecticut Volunteer Angler Survey (ISC))
- Date (mm/dd/yy)/start time (check box AM/PM)
- Fishing mode (Shore, EOS, Private Boat, Charter Boat and Party Boat)
- Total number of fish kept and released
- Length measurements for the first seven fish caught.

## Catch Card Tracking

Both the IFC and ISC catch cards were distributed to anglers and categorized by identification number, date, site, and mode. A tally sheet was provided to field personnel for tracking purposes. However, as the survey progressed, the ISC card distributed by tackle shops also proved to be more suitable for distribution by DEEP staff encountering anglers fishing in different modes. The ISC card incorporated a fishing area map including fishing mode check off boxes where the IFC did not. During May through November, a total of 3,603 catch cards were given out to marine recreational anglers. The breakdown by mode was 2,193 cards for the PBM, 1,106 cards for ESO, 302 cards for Shore Mode, and one each for the Charter and Party Boat Mode. A total of 605 cards or about $17 \%$ were returned. In addition, a total of 834 vessel registrations were collected. Of that total, about $80 \%$ were Connecticut registered vessels and the remainder ( $20 \%$ ) were out of state vessels.

## Catch Information

An angler's total catch for the trip including common name(s) and number of fish kept and released were tallied and written in the spaces provided on the catch card (group catches were not included). If no fish were caught a check off box was provided to indicate so. A total of 4,373 fish were caught (Table 1.1). PBM anglers caught over $74 \%$ of the fish. The EOS Mode comprised about $22 \%$ and the Shore Mode $4 \%$ of the total catch. Scup were the most frequent fish anglers caught in all modes combined ( $33.9 \%$ ) with bluefish next at $20.1 \%$ and black sea bass third at $13.1 \%$. The percent of fish kept by anglers was the highest in the EOS Mode (34.7\%). Furthermore, EOS Mode anglers kept about 53\% of scup caught. EOS Mode scup and summer flounder minimum length regulations are less restrictive than other fishing modes in order to give anglers a better chance of bringing home fish for consumption purposes. The minimum length for scup was reduced from $101 / 2$ inches to 9 inches and summer flounder from $171 / 2$ to 16 inches total length at EOS fishing sites (Appendix 1.3). There were 46 shore fishing sites along the Connecticut shoreline designated as EOS Mode fishing sites.

## Length Information

Each individual angler entered common name(s) of the first seven fish captured regardless of species and size on both survey catch cards. Each fish was measured to the nearest $1 / 2$ inch (rounded down) and record disposition by circling either Y (yes) or $N$ (no) in the Kept column. Anglers measured a total of 1,795 fish (Table 1.2). Anglers fishing from boats measured about $80 \%$ of the catch with EOS Mode anglers comprising near $18 \%$ of the total measured catch. Scup, summer flounder, black sea bass, bluefish, and striped bass were the most
frequently measured fish by anglers comprising $84 \%$ of the total measured catch. Length frequencies for those popular marine fish are described in Figure 1.1.

## MODIFICATIONS

For 2014, the EOS Mode and the Private Boat Mode will be sampled separately. The EOS Mode will be sampled using volunteer catch cards in addition to a roving creel bus stop design in order to collect effort and estimating catch. The Private Boat Mode will be sampled using catch cards.

## JOB 1: MARINE ANGLER SURVEY <br> PART 2: VOLUNTEER ANGLER SURVEY <br> OBJECTIVES

Provide estimates of:

1) Size composition data on both kept and released bluefish, striped bass other common species.

Anglers participating in the Volunteer Angler Survey measured bluefish, striped bass and other species. Length frequencies of popular species: bluefish, striped bass, summer flounder, winter flounder, scup, tautog and black sea bass are listed in Tables 1.1A-1.7A.
2) Catch frequency (trips catching 0,1,2,...fish) data on both kept and discarded fish.

Catch frequency data and percent distribution on both kept (harvested) and released for selected species are listed in Tables 1.8A-1.9A.

## INTRODUCTION

The purpose of the Volunteer Angler Survey (VAS) is to supplement the National Marine Fisheries Service, Marine Recreational Fishery Statistics Survey/Marine Recreational Information Program by providing additional length measurement data particularly concerning fish that are released. In 1994, the VAS program was incorporated into the Marine Angler Survey (Job 1) in order to improve and expand the survey.

The survey's initial objective was to collect marine recreational fishing information concerning finfish species with special emphasis on striped bass. In 1994, the collection of bluefish length measurements was added to the survey to fully understand that fishery. In 1997, length measurement information on other marine finfish was added to the survey. This report primarily consists of data collected in 2013.

## METHODS

The VAS is designed to collect trip and catch information from marine recreational (hook and line) anglers who volunteer to record their fishing activities by logbook. The logbook format consists of recording fishing effort, target species, fishing mode (boat and shore), area fished (subdivisions of Long Island Sound and adjacent waters), catch information concerning finfish kept (harvested) and released, and striped bass and bluefish length measurements. In 1997, the logbook was modified in order to collect length measurement data on other species. Instructions for volunteers were provided on the inside cover of the postage paid logbook. Each participating angler was assigned a personal numeric code for confidentiality purposes. After the logbook data were computer entered, logbooks were returned to each volunteer for their own personal record. Furthermore, to improve communications with recreational anglers and to encourage
more public input, volunteers were notified of upcoming public hearings including proposed and final changes in recreational fishing regulations.

New in 2013, the VAS program was incorporated into the Atlantic Coastal Cooperative Statistics Program (ACCSP) Standard Atlantic Fisheries Information System (SAFIS) eLogbook application. Under the ACCSP eLogbook application, the VAS database was upgraded from the previous outdated database system it was using. The VAS logbook format was slightly modified so that the information collected would be compatible with Atlantic Coast Cooperative Statistics Program (ACCSP) minimum data element standards (Appendix 1.1A).

## RESULTS AND DISCUSSION

Over the years the number of participants in the survey ranged from as low as 18 anglers participating in 1979 to a high of 115 anglers in 1997. Advertising the VAS program through the DEEP's annually published Connecticut Angler's Guide including the state web site www.ct.gov/dep has helped increase volunteer participation. The guide is distributed to anglers purchasing Connecticut fishing licenses in addition to being circulated by bait and tackle shops and other entities.

Initially in 2012 with the VAS database being housed and updated under ACCSP SAFIS, one of the primary purposes was that anglers would be able to enter their own fishing information and compile their own statistics using eLogbook. However, a data entry problem occurred concerning the 'fishing area' field. Because of the unique geographic location of Connecticut's shoreline including Long Island Sound, marine anglers can fish over multiple areas crossing interstate and federal boundaries during a single trip. Unfortunately, eLogbook software disabled data entering of certain 'fishing area' fields outside of Connecticut's marine waters. Until this problem was to be resolved, the concept of electronic reporting by volunteer anglers was postponed until 2014. As in previous years, paper logbooks were distributed to survey volunteers and Marine Fisheries staff performed VAS data entry.

## VAS 2013

In 2013, a total of 37 anglers participated in the survey and made 884 fishing trips. The average number of trips volunteers took was about 23 trips per year and the range was 3 to 143 trips (Figure 1.1A). Volunteers including additional anglers involved in a fishing party made a total of 1,642 fishing trips.
 Private boat mode trips comprised $67 \%$ and shore based anglers consisted $30 \%$ of the total trips taken by anglers (Figure 1.1B).

VAS anglers pursued and caught a wide range of inshore and offshore pelagic species and recorded length measurements on many species. VAS anglers caught a total of 9,243 fish.

Of that total 7,462 fish or $80.7 \%$ were released. Black sea bass, bluefish, scup, striped bass, and summer flounder accounted for $78.5 \%$ of the total catch. Scup was the most frequently caught fish followed by summer flounder, striped bass, and black sea bass (Table 1.1A). The Private Boat mode comprised $81.1 \%$ of the total catch for all modes combined. Volunteers measured 3,803 fish or

Figure 1.2A: Fishing Trip Distribution by Mode

■ Charter Boat

- Headboat
- Private Boat

Shore about $41 \%$ of the total catch. Of the total catch, 893 ( $50.1 \%$ ) fish kept and 2,910 ( $39 \%$ ) fish released were measured. Summer flounder were the most frequent fish $(1,042)$ measured by VAS anglers. Other popular species measured included black sea bass (367), bluefish (380), scup (414), striped bass (753), searobins (477), and tautog (165) (Figures 1.3A-1.8A).

## CONCLUSIONS

VAS anglers provide valuable recreational fisheries data at a relatively low cost. In addition, collecting length data on released fish is often difficult or unattainable through conventional access point angler intercept surveys. The VAS program provides this information which is essential in assessing the recreational fishery in Connecticut as required by the Atlantic States Marine Fisheries Commission. Any anglers interested in participating in the program can contact Rod MacLeod at 860-434-6043, or e-mail address: rod.macleod@ct.gov or writing to State of Connecticut, DEEP, Marine Fisheries Office, P.O. Box 719, Old Lyme CT 06371.

## MODIFICATIONS

For 2014, the VAS logbook will be made available in both electronic and paper logbook form to all participants. All reported data by VAS anglers will be stored in the central ACCSP SAFIS data warehouse.

## ACKNOWLEDGMENTS

I am very grateful to all anglers who have participated in the survey. Without their cooperation and assistance, the VAS program would not be possible.

APPENDIX 1.1A: Connecticut Volunteer Angler Logbook

## VOLUNTEER ANGLER SUVEY INSTRUCTIONS (CONTINUED)

Trip Catch Record
Under each trip effort record are the associated catch records. Enter a catch row for each species, disposition (Kept/Released) and length. If you

 and effort information (Date to Targeted Species 2).

Species Enter the species code from the Species Code List below. If the species is not listed, write in the species name.

Indicate if the fish were kept or released by writhing K (Kept) or
 indicate this by adding an additional row. If you kept and released the same species, complete two rows.

Enter the length in inches of the fish. ROUND DOWN TO THE
 Angler Survey requested rounding to the nearest half inch but rounding down helps produce more accurate data.

Enter the number of fish of that specific species, disposition

 page.

## VOLUNTEER ANGLER SURVEY INSTRUCTIONS

Listed below are instructions for filling out the logbook. Upon logbook completion, tape the prepaid postage logbook shut and drop it off in the mail. All information is kept confidental. Once the information is enter If you are interested in online reporting please contact us. The information provided by this report will help us in making fishery management decisions. Please help us by completing this report as accurately as possible.

 @ct.gov) at 860.434.6043. Trip Header Record
The top of each page is for recording each trip's header information. In
 before the trip is over, continue onto the next page. Use as many pages and
 trip, make only one entry for that trip.

## Date Enter the date that your fishing trip occurred on.

Start Time Enter the time on a 24 hour clock (military time) that you started your fishing trip.
 appropriate box. The Shore (Enhanced Site) option refers to anglers guide for more information. Trip Effort Record

Enter the approprate fishing effort information for the fishing area.
Fishing Enter the code for the area in which you made your catch. Refer to the Fishing Area Chart on page iii for the appropriate
area 6 and 147, please use area code 6.
Enter the total number of anglers that are in the fishing party.
Enter the number of anglers that caught fish in the fishing
Enter the actual fishing time or 'lines wet' to the nearest half hour. Do not include travel time.
 targeted species.

## JOB 2 PART 1: LONG ISLAND SOUND TRAWL SURVEY (LISTS)

## CRUISE RESULTS FROM THE 2013 <br> SPRING AND FALL SURVEYS

## STUDY PERIOD AND AREA

The Connecticut DEEP Marine Fisheries Division completed the thirtieth year the Long Island Sound Trawl Survey in 2013. The Long Island Sound Trawl Survey encompasses an area from New London to Greenwich, Connecticut and includes waters from 5 to 46 meters in depth in both Connecticut and New York state waters. Typically, Long Island Sound is surveyed in the spring, from April through June, and during the fall, from September through October. This report includes results from the 2013 spring and fall sampling periods and provides time series information since the commencement of the survey in 1984.

## GOAL

To collect, manage, synthesize and interpret fishery independent data on the living resources of Long Island Sound for fishery management and information needs of Connecticut biologists, fishery managers, lawmakers and the public.

## OBJECTIVES

1) Provide an annual index of counts and biomass per standard tow for 40 common species.
2) Provide age specific indices of abundance for scup, summer flounder, tautog and winter flounder.
3) Provide a recruitment index for bluefish (age 0) and weakfish (age 0).
4) Provide length frequency distributions of black sea bass, bluefish, scup, striped bass, summer flounder, tautog, weakfish, winter flounder, and other ecologically important species suitable for conversion to age using modal analysis, age-length keys or other techniques.
5) Provide annual total counts and biomass for all finfish species taken.
6) Provide annual total biomass for all invertebrate species taken.
7) Provide a species list for Long Island Sound based on LIS Trawl Survey sampling, noting the presence of additional species from other sampling conducted by the Marine Fisheries Division.

## INTRODUCTION

The Long Island Sound Trawl Survey (LISTS) was initiated in 1984 to provide fishery independent monitoring of important recreational species in Long Island Sound. A stratifiedrandom design based on bottom type and depth interval was chosen and forty sites were sampled monthly from April through November to establish seasonal patterns of abundance and distribution. Seven finfish species were initially of primary interest: bluefish, scup, striped bass, summer flounder, tautog, weakfish, and winter flounder. Length data for these species were collected from every tow; scup, tautog, and winter flounder were sampled for aging. Lobster were also enumerated and measured from every tow. All fish species were identified and counted.

Since 1984, several changes have been incorporated into the Survey. In 1991, the sampling schedule was changed to a spring/fall format, although sampling is still conducted on a monthly basis (April - June, September, and October). Beginning in 1992, species were weighed in aggregate with an onboard scale to provide indices of biomass. Furthermore, more species have been sampled for lengths, such as windowpane and fourspot flounders, and important forage species such as butterfish, long-finned squid, and several herring species. By 2003, the list of species measured expanded to 20 finfish species and two invertebrate species (lobster and long-finned squid). In addition, rarely occurring species (totaling less than 30 fish/year each) are now measured and age structures are collected from bluefish, menhaden, tautog, scup, winter flounder, weakfish and large summer flounder ( $>59 \mathrm{~cm}$ ). All of these changes serve to improve the quality and quantity of information made available to fishery managers for local and regional assessment of stock condition, and to provide a more complete annual inventory of LIS (Long Island Sound) fishery resources.

## METHODS

## Sampling Design

LISTS is conducted from longitude $72^{\circ} 03^{\prime}$ (New London, Connecticut) to longitude $73^{\circ}$ 39' (Greenwich, Connecticut). The sampling area includes Connecticut and New York waters from 5 to 46 m in depth and is conducted over mud, sand and transitional (mud/sand) sediment types. Sampling is divided into spring (April-June) and fall (Sept-Oct) periods, with 40 sites sampled monthly for a total of 200 sites annually. The sampling gear employed is a 14 m otter trawl with a 51 mm codend (Table 2.1). To reduce the bias associated with day-night changes in catchability of some species, sampling is conducted during daylight hours only (Sissenwine and Bowman 1978).

LISTS employs a stratified-random sampling design. The sampling area is divided into $1.85 \times 3.7 \mathrm{~km}$ ( $1 \times 2$ nautical miles) sites (Figure 2.1), with each site assigned to one of 12 strata defined by depth interval ( $0-9.0 \mathrm{~m}, 9.1-18.2 \mathrm{~m}, 18.3-27.3 \mathrm{~m}$ or, $27.4+\mathrm{m}$ ) and bottom type (mud, sand, or transitional as defined by Reid et al. 1979). For each monthly sampling cruise, sites are selected randomly from within each stratum. The number of sites sampled in each stratum was determined by dividing the total stratum area by $68 \mathrm{~km}^{2}$ ( 20 square nautical miles), with a minimum of two sites sampled per stratum (Table 2.2). Discrete stratum areas smaller than a sample site are not sampled.

## Sampling Procedures

Prior to each tow, temperature $\left({ }^{\circ} \mathrm{C}\right)$ and salinity ( ppt ) are measured at 1 m below the surface and 0.5 m above the bottom using a YSI model $30 \mathrm{~S}-\mathrm{C}-\mathrm{T}$ meter. Water is collected at depth with a five-liter Niskin bottle, and temperature and salinity are measured within the bottle immediately upon retrieval.

The survey's otter trawl is towed from the 15.2 m aluminum R/V John Dempsey for 30 minutes at approximately 3.5 knots, depending on the tide. At completion of the tow, the catch is placed onto a sorting table and sorted by species. Finfish, lobsters and squid are counted and weighed in aggregate (to the nearest 0.1 kg ) by species with a precision marine-grade scale ( 30 $\mathrm{kg},+/-10 \mathrm{gm}$ capacity). Catches weighing less than 0.1 kg are recorded as 0.1 kg . During the initial two years of the survey ( $1984 \& 1985$ ), lobsters were the only invertebrates recorded. Squid abundance has been recorded since 1986. Since 1992, additional invertebrate species have been weighed in aggregate, and some have been counted. The complete time series of species counted and weighed in the survey is documented in Appendix 2.4.

For selected finfish species, lengths are recorded to the centimeter as either total length or fork length (e.g. measurements from 100 mm to 109 mm are recorded as 10 cm ) and entered in the database as 105 mm (Table 2.3). Lobsters are measured to 0.1 mm carapace length. Squid are measured using the mantle length ( cm ), horseshoe crab measurements are taken using prosomal width (cm) and whelk (knobbed and channeled) shell widths are measured in milimeters.

The number of individuals measured from each tow varies by species, and also depends on the size of the catch and range of lengths (Table 2.3). If a species is subsampled, the length frequency of the catch is determined by multiplying the proportion of measured individuals in each centimeter interval by the total number of individuals caught. Some species are sorted and subsampled by length group so that, for example, all large individuals are measured and a subsample of small (often young-of-year) specimens is measured. All individuals not measured in a length group are counted. The length frequency of each group is estimated as described above, i.e. the proportion of individuals in each centimeter interval of the subsample is expanded to determine the total number of individuals caught in the length group. The estimated length frequencies of each size group are then appended to complete the length frequency for that species. This procedure is often used with catches of bluefish, scup, and weakfish, which are usually dominated by young-of-year or discrete age/length classes.

Bluefish, menhaden, scup, summer flounder, tautog, weakfish (ageing was discontinued in 2013) and winter flounder are sampled for age determination (Table 2.3). The target number of age samples (otolith) for bluefish were 50 from the spring period (defined by ASMFC Bluefish Technical Committee as Jan-July) and 50 from the fall period (August-December). Subsamples of scup, stratified by length group, are measured to the nearest mm (fork length) and scales from each individual are taken for ageing. Scup scales are removed posterior to the pectoral fin and ventral to the lateral line. The scales are pressed onto plastic laminate with an Ann Arbor roller press to obtain an impression of the scale, which is then viewed with a microfiche reader at 21x. Scales are also taken from all summer flounder greater than 59 cm . At least 15 scales are removed from the caudal peduncle area. These scales are pressed and aged to
supplement the National Marine Fisheries Service age key and are also included in the formulation of LISTS summer flounder catch-at-age matrix (see below).

Menhaden scales are collected from roughly 50 fish each year as required by Amendment 2 of the ASMFC Atlantic menhaden management plan. Amendment 2 introduced a requirement for biological sampling of the commercial bait harvest to support improved stock assessments. However since Connecticut has such a small menhaden commercial fishery, sampling it would be difficult. The same size/age component of the menhaden population taken in the commercial fishery is available to LISTS so collections are taken as part of each survey cruise. Menhaden fork length (mm), and sex are recorded and scales are taken about mid-body (lateral line) and below the insertion of the dorsal fin. Most tautog taken in LISTS are aged due to the low numbers caught in recent years (under 250 fish). Tautog are iced and taken to the lab, where their total length (mm), sex, and total weight (gm) are recorded and their age is determined from opercular bones (Cooper 1967). At the request of the ASMFC Tautog Technical Committee, LISTS began collecting tautog otoliths in addition to opercles in 2012. Results from a recent ASMFC Tautog Ageing Workshop (May 2012) indicated there was no clear benefit to switching from opercles to otoliths for CT, so tautog otoliths will be collected (minimum of 50 per/ASMFC) and archived for potential use in the future. Subsamples of winter flounder, stratified by length group and area (as listed in bottom of Table 2.3), are iced and taken to the lab where they are measured to the millimeter (total length), weighed (gm) and sexed. Their maturity stage is determined (NMFS 1989), and they are aged with whole and/or sectioned otoliths (Simpson et al. 1988). Weakfish scales are obtained and processed as described above for scup, and prior to 2013 otoliths were sectioned and read using procedures described in Simpson et al. 1988. Ageing structures for weakfish were collected in 2013 but not aged. LISTS will discontinue weakfish collections in 2014 (see modifications).

In reports prior to 2001, three species were not included in annual and seasonal totals: American sand lance, bay anchovy, and striped anchovy. These species, with the possible exception of striped anchovy, can be very abundant in Long Island Sound, but are not retained well in the otter trawl. Additionally, many of these fish are young-of-year and often drop out of the net as it is retrieved and wound on the net reel. For this reason they were not included in the list of species to be counted when LISTS was started in 1984. However, to document the occurrence of these species in LISTS catches, American sand lance was added in 1994, striped anchovy was added in 1996, and bay anchovy was added in 1998. Since 2001, adults of these three species have been included in the annual and seasonal totals and the young-of-year are listed if present in the year's catch but are not quantified (Table 2.15, Appendix 2.4). Young-ofyear for these three species are included in the database but are cataloged with a separate species identifier and quantities are considered estimates (Appendix 2.2).

In 2013, the only endangered species encountered by LIS Trawl Survey was Atlantic sturgeon, a species that was listed as Endangered by NOAA in 2012. Sampling procedures have been modified in recent years to minimize the likelihood of injury to Atlantic sturgeon. When sampling in a season and area where the chance of catching a sturgeon is high (based on historic LISTS catch) and water depth is greater than 27 m , gear retrieval speed is reduced to decrease the stress induced by rapid changes in pressure. When a sturgeon is detected in the net, it is removed as quickly and carefully as possible. Subsequent handling and processing follow protocols described in A Protocol for Use of Shortnose, Atlantic, Gulf, and Green Sturgeons (Kahn and

Mohead. 2010. U.S. Dep. Commerce, NOAA Tech Memo, NMFS-OPR-45, 62p., http://www.nmfs.noaa.gov/pr/pdfs/species/kahn_mohead_2010.pdf) and adhere to the Reasonable and Prudent Measures, as well as, the Terms and Conditions spelled out in the ESA Section 7 Biological Opinion's Incidental Take Statement issued by NOAA for CT in June 2012 (http://www.greateratlantic.fisheries.noaa.gov/protected/section7/bo/oldbiops/usfws_state_of_ct marine_surveys_2012_web_archive.pdf). Future LISTS interactions with sturgeon will follow requirements of the subsequent biological opinion issued by NOAA for the 11 Northeast States and District of Columbia. All interactions with endangered species are reported in Appendix 2.5.

## Data Analysis

## Indices of Abundance: Annual Mean Count and Weight per Tow

To evaluate the relative abundance of common species, an annual spring (April - June) and fall (September - October) geometric mean number per tow and weight per tow (biomass, kg ) is calculated for the common finfish and invertebrate species. To calculate the geometric mean, the numbers and weight per tow are $\operatorname{logged}\left(\log _{e}\right)$ to normalize the highly skewed catch frequencies typical of trawl surveys:

$$
\text { Transformed variable }=\ln (\text { variable }+1)
$$

Means are computed on the log scale and then retransformed to the geometric mean:
geometric mean $=\exp ($ mean $)-1$.
The geometric mean count per tow was calculated from 1984-2013 for 38 finfish species, lobster, and long-finned squid (1986-2013). The geometric mean weight per tow was calculated using weight data collected since 1992 for the same species, plus an additional 13 invertebrates.

For the seven finfish species that were measured on every tow (bluefish, scup, striped bass, summer flounder, tautog, weakfish, and winter flounder) biomass indices were calculated for the years 1984-1991 by using length/weight equations to convert length frequencies to weight per tow. Bluefish, scup, weakfish and winter flounder lengths were converted using equations from Wilk et al. 1978; striped bass conversions were accomplished using an equation from Young et al. 1994; summer flounder and tautog conversions were accomplished using equations developed from LISTS data from 1984-1987 and 1984-1996 respectively.

## Indices of Abundance: Indices-at-Age and Age Group

Annual age specific indices (indices-at-age matrices) were calculated for scup, striped bass, summer flounder, winter flounder and tautog. The age data used to calculate the indices came from three sources: striped bass ages were derived using the von Bertalanffy (1938) equation; summer flounder age-length keys were obtained from the National Marine Fisheries Service (NMFS) Northeast Fisheries Science Center spring and fall trawl surveys combined with LISTS ages ( $>59 \mathrm{~cm}$ ); scup, winter flounder and tautog age-length keys (in 1 cm intervals) were obtained directly from LISTS. Since fish growth can fluctuate annually as a function of population size or other environmental factors, a year and season specific age-length key was used wherever possible. Once lengths have been converted to age, the proportion at age is
multiplied by the abundance index of the appropriate season to produce an index of abundance at age.

Recruitment (young-of-year) and age $1+$ (all fish age one and older) indices were calculated for bluefish and weakfish. Observed modes in the length frequencies were used to separate the two groups.

The specific methods used to calculate indices-at-age for each species were as follows:

- Bluefish. Otoliths were taken from 227 bluefish, 62 from the spring period and 151 from the fall period. Of the 62 samples taken in the spring, only 20 were obtained from LISTS; the bulk of the samples came from recreational anglers. Most of the fall samples were obtained from LISTS ( 151 fish) although 14 samples were obtained through donations from a fishing tournament. . In 2012 a coast wide biological sampling program was initiated through ASMFC addendum 1 of the bluefish management plan. Since there is only two years of data from the northeast, there are still limited results available at this time. Therefore, the method of using modes observed in the fall length frequencies to separate bluefish into age 0 and age $1+$ groups, and calculate a geometric mean catch per tow for each group (Table 2.22) was continued through 2013. Comparison of the mean length-at-ages reported for young-of-year and age 1 bluefish in the New York Bight (Chiarella and Conover 1990) and Long Island Sound (Richards 1976) with LISTS length frequencies suggests that bluefish can easily be identified as either age 0 (snapper bluefish) or adults (age 1+). Richards (1976) and Chiarella and Conover (1990) determined that most bluefish less than 30 cm are age 0 . A discontinuity in the LISTS fall length frequencies occurs most years between 26 cm and 39 cm (Table 2.42). Therefore 30 cm was determined to be a suitable length for partitioning age 0 and age one fish. With the addition the biological sampling programs along the coast, either a regional northeast key will be developed or possibly just using the LISTS key will be utilized for calculating a full index-at-age for Long Island Sound.

Prior to 2012, there was limited bluefish ageing in the northeast. Although North Carolina state biologists have aged bluefish for some time, their age keys were not used to age Long Island Sound bluefish because North Carolina mean lengths-at-age are not consistent with modes observed in Long Island Sound bluefish length frequencies. This difference suggests that growth may vary by region, or that early and late spawned bluefish may be differentially distributed along the coast (Kendall and Walford 1979).

- Scup. An index-at-age matrix was developed for 1984-2013 using spring (May-June only) and fall (September-October) LISTS data (Table 2.23). April data was omitted since very few scup are taken at this time. A total of 12,221 scup aged between 1984 and 2013 were used to make year and season specific age-length keys ( 1 cm intervals). In the relatively few instances when the season/year specific key failed at a given 1 cm length interval, a three-year pooled key was used to determine the age. Three-year pooled keys were calculated using the years proceeding and following the "run" year. For the terminal year, only two years were used for the pooled key. The final index-at-age was computed for both spring and fall indices-at-age. Since very few scup older than age 9 are taken (less than $4 \%$ in any given year), an age $10+$ group is calculated by summing
indices for ages 10 and up. To represent the full adult portion of the population an age $2+$ index is calculated by summing the indices for ages 2 through $10+$.
- Striped bass. To approximate the ages of striped bass taken in the spring survey (Table 2.24), the average of the Chesapeake Bay and Hudson River striped bass von Bertalanffy parameters ( $\mathrm{L}_{\max }=49.9 \mathrm{in}, \mathrm{K}=0.13, \mathrm{t}_{\mathrm{o}}=0.16$, Vic Crecco, pers. comm.) were used in the rearranged von Bertalanffy equation:

$$
\mathrm{t}=(1 / \mathrm{K}) *\left(-\log _{\mathrm{e}}\left(\left(\mathrm{~L}_{\max }-\mathrm{L}_{\mathrm{t}}\right) / \mathrm{L}_{\max }\right)\right)+\mathrm{t}_{\mathrm{o}}
$$

Since this equation estimates age $t$ as a fraction of a year, the estimates were rounded to the nearest year (e.g. age $3=$ ages 2.5 to 3.4). A spring catch-at-age matrix was developed for 1984 through 2013 by apportioning the spring index by the percentage of fish at each age (Table 2.25).

- Summer flounder. The year and season specific age-length keys ( 1 cm intervals) used to age LISTS catches were provided by NMFS from their spring and fall trawl surveys. These keys were supplemented with fish caught and aged by LISTS (typically 60 cm and over). In 2013 LISTS had sample requests for summer flounder and scale samples from these fish ( $<60 \mathrm{~cm}$ ) were collected. In 2013, 163 summer flounder, were aged; 157 from the spring and 6 (all $>60 \mathrm{~cm}$ ) from the fall. Since 2001, whenever the season/year specific key failed at a given 1 cm length interval a pooled year key using only adjacent years was used (Gottschall and Pacileo 2002). Since it is thought that growth rates for summer flounder have changed over time, a pooled key using only adjacent years would more accurately represent fish that could not be aged by the season/year specific key. Using this methodology, the catch-at-age matrix (Table 2.26) will remain unchanged for all but the terminal year, which will be updated as the following years' data becomes available.
- Tautog. An index-at-age matrix was developed for 1984-2013 using all survey months (Gottschall and Pacileo 2007) (Table 2.27). During 2013, 165 tautog were captured and opercles were collected from all; 129 collected in the spring and 36 were collected in the fall. Ageing for 2006-2012 has been completed. Ageing for 2013 samples has not yet been completed. A 2012 age key was used for the 2013 un-aged fish and a pooled key was used where the 2012 key failed. Therefore, the 2013 indices-at age are preliminary; the 2013 tautog samples will be aged during the summer of 2014 and an updated index-at-age matrix will be constructed.
- Weakfish. Age 0 and age $1+$ indices were calculated for both spring (1984-2013) and fall surveys (1984-2009, 2013) (Table 2.28). Since few weakfish are taken in April, the spring geometric mean was calculated using only May and June. All weakfish taken in spring are assumed to be age $1+$. Similar to bluefish, the fall age 0 and $1+$ indices were calculated by using length frequencies to separate the catch. Since a break in the fall length frequencies generally occurs between 24 and 32 cm each year (Table 2.57), weakfish less than 30 cm are considered to be age 0 while those greater than or equal to 30 cm are ages $1+$.
- Winter flounder. An index-at-age matrix was developed for 1984-2013 using April and May LISTS data (Table 2.29). June data were not used since length frequency data suggest that many adult winter flounder have left the Sound by this time (an exception was made for 1984, the first year of LISTS, because very few samples were taken in the spring months). A total of 22,671 winter flounder aged between 1984 and 2013 were used to make year and region (east of Stratford Shoal, west of Stratford Shoal) specific age-length keys in 1 cm intervals. Similar to scup and summer flounder, three year pooled keys using only the adjacent years (two years for the terminal year runs) were used to assign ages if year specific keys were not available.

Each flounder aged as described above was also assessed for maturity stage (following Burnett 1989) by sex. CT DEEP staging of winter flounder was verified in a cooperative study with NMFS in 2009-2010 (Gottschall and Pacileo 2011). The percentage of male and female fish in each centimeter length group that was sexually mature (ripe, resting, or spent) was calculated in order to determine the length group at which $50 \%$ was mature each year.

## Species Richness by Group

The Long Island Sound Trawl Survey monitors species richness using groups of species classified as either cold temperate or warm temperate. For the purposes of tracking species richness, American sand lance, bay anchovy, and striped anchovy were omitted (see Sampling Procedures section). All other finfish species captured in LISTS were divided into groups based on their temperature preferences and seasonal spawning habits as documented in the literature (Collette and Klein-MacPhee 2002, Murdy et al. 1997). Species in the cold temperate group prefer water temperatures below $15^{\circ} \mathrm{C}\left(60^{\circ} \mathrm{F}\right)$, tend to spawn at the lower end of their temperature tolerance range, and are more abundance north of Long Island Sound than south of New York. Species in the warm temperate group prefer warmer temperatures $\left(11-22^{\circ} \mathrm{C}\right.$ or $\left.50-77^{\circ} \mathrm{F}\right)$, tend to spawn in the upper range of their temperature tolerance, and are more abundant south of the Sound than north of Cape Cod (Appendix 2.6). Species that are not tolerant of cold temperatures, are abundant only south of Chesapeake Bay but stray into northern waters mostly as juveniles, and spawn only in the mid-Atlantic Bight and south were placed into a separate group (subtropical) and were not included in the analysis because they are typically only present in the fall LISTS.

## Open Water Forage Abundance

A Long Island Sound open water forage index of abundance was compiled to measure the available food base which supports resident and migratory species within the Sound. This index is formulated as a biomass index that is assembled from 11 of the forage species that are most common in LISTS catches along with three other species that are considered forage at an early life stage (young-of-year, YOY). The species used to generate the index are; Atlantic herring, long-finned squid, butterfish, alewife, blueback herring, American shad, hickory shad, menhaden, whiting, spotted hake, and red hake along with young-of-year stage of scup, bluefish, and weakfish. The geometric mean biomass is calculated using the aggregate of these 14 species on a per tow basis and calculated using the same methodology as described above for individual species biomass indices.

## RESULTS AND DISCUSSION

## Overview of LISTS 2013 Spring and Fall Surveys

Each month of the survey, sampling aboard the R/V John Dempsey generally began in the east end of Long Island Sound and progressed westward. The April survey commenced on April 9, 2013, and continued until April 25 for a total of nine (9) days underway and 40 tows completed. May sampling started on May 7 and continued till May 21 with nine (9) sampling days underway and 40 sites completed. June sampling began on June 10 and ended on June 27, taking eleven (11) days underway to complete the 40 sites. The Fall Survey needed 10 days underway in September and 9 days underway in October to complete the 40 sites in each of the months. A total of 200 LISTS tows were completed in 48 days underway during the spring and fall 2012 surveys (Table 2.4); not including transit days or weather days.

Maps showing the sites selected versus the sites sampled during each month of sampling are provided in Figure 2.2 (April), Figure 2.3 (May), Figure 2.4 (June), Figure 2.5 (September) and Figure 2.6 (October). Within each figure the red bordered sites are the sites selected for the month and the solid blue dots indicate the actual sites sampled. If a site had to be relocated during sampling, an explanation of why it was moved is provided under the figure. Additional site/station information is provided in Table 2.5 (April), Table 2.6 (May), Table 2.7 (June), Table 2.8 (September) and Table 2.9 (October). These tables provide date of sample, time, tow duration, latitude/longitude, surface and bottom temperature and salinity, average tow speed, distance towed and approximate area swept for each tow.

Sometimes, a full 30-minute tow cannot be completed. Typical reasons for short tows include lack of room because of observed pot gear set in the immediate area, a drop in speed due to entanglement with some object on the bottom (frequently derelict pot gear), or a complete stop in forward motion (submerged wreck or rock pile). Survey crew will often attempt to finish an interrupted tow by clearing the net (if needed) and resetting beyond the obstruction or observed gear. If this is not possible, a site may have to be moved to another site nearby with the same stratum (bottom type and depth). If the site was moved, the data from the initial site will not be used. Typically, a minimum of 15-20 minutes is required for a LISTS tow to be recorded. However, there are occasions when a tow with less than 15 minutes will be accepted, usually because there is no alternate site in the designated strata in the vicinity. Short tow information for each month in the 2013 survey is summarized in Table 2.10.

## Cooperative Sample and Data Collection

Throughout the time series, LISTS staff have been participating in cooperative efforts for sample collections, data requests, and special projects using survey personnel, equipment, and other resources. Most of these cooperative efforts are with state researchers or agencies, the National Marine Fisheries Service, Atlantic States Marine Fisheries Commission, New England and Mid-Atlantic Councils, and researchers or graduate students associated with state or local universities. Table 2.11 illustrates many of the organizations that requested data in 2013, while Table 2.12 shows sample request received and fulfilled. In recent years many requests for samples have come from high schools, aquariums, or other educational organizations needing finfish and invertebrates for teaching purposes. Additionally, our own staff often have sample or data requests for media or other public outreach events (see Job 6 of this report).

## Number of Species Identified

Fifty-five finfish species were observed in the 2013 Long Island Sound Trawl Survey (Table 2.13). This includes one new species for the survey; two bullnose ray (Myliobatis freminvillei, shown at right), were caught on two separate tows during the fall survey. From 1984 to 2013, LIS Trawl Survey has identified one hundred four (104) finfish species (Appendix 2.1), averaging 58 species per year with a range of 43 to 70 species ( Fig 2.7). In addition, a total of 41 types
 of invertebrates were collected in 2013 (Table 2.14). Most invertebrates are identified to species. However, in some cases, invertebrates were identified to genus or a higher level taxon.

## Total Catch

Appendix 2.4 presents a time series (1984-2013) of the finfish species collected each year and their respective rank by numbers. Annual total biomass of invertebrates is also included in this appendix (1992-2013), ranked by weight (kg).

A total of 83,413 finfish weighing $15,844 \mathrm{~kg}$ were sampled in 2013 (Table 2.15). In twenty-one out of the last thirty years butterfish has been the highest-ranking finfish (numbers) in LISTS. In 2013, LISTS caught less than half of the butterfish (29,569 fish) seen just one year earlier yet this species still accounted for $35.4 \%$ of the catch by number and $7.9 \%$ of the biomass. Scup was the second most abundant by number $(24,961)$ and the most abundant by weight, accounting for $37.5 \%$ of the biomass in 2013. Typically, scup and butterfish account for $60 \%$ of the Trawl Survey annual catch (range $27.1 \%-86.0 \%, 1984-2013$, Appendix 2.4) and have been among the five most abundant species caught (by number) each year of the thirty-year LISTS time-series. Scup was more abundant than butterfish in the spring survey, however, butterfish was the more abundant species in the fall (Table 2.16). The top five species (by number) in 2013, in order of decreasing abundance, were butterfish, scup (porgy), Atlantic herring, striped searobin, windowpane flounder and weakfish. These five species accounted for $77.8 \%$ of the total annual catch and $57.8 \%$ of the total biomass.

A total of 39,539 finfish weighing $9,713 \mathrm{~kg}$ were sampled in spring of 2013 (Table 2.16). Scup topped the spring catch both by number and biomass, with 17,037 fish ( $4,690.6 \mathrm{~kg}$ ) accounting for $43.1 \%$ of the catch numerically and $48.3 \%$ by weight. The scup index of abundance for spring 2013 ( 14.23 scup per tow) was the eighth highest in the time-series, making 2013 the eighth time in the past 14 years that the springtime index has been above the time-series mean of 11.66 scup per tow (Table 2.18). Scup from 10 to 32 centimeters fork length were most prominent in the length frequency distribution. Three modes were present at 11, 19, and 29 centimeters. The smaller size group often seen in the spring ( $10-12 \mathrm{~cm}$ ) were much less abundant then what was observed in 2012, but nonetheless present this past spring. The number
of scup greater than 30 cm in springtime catches has been increasing for the past decade (Table 2.52).

Butterfish were much less abundant during the spring of 2013 but still was the second most abundant species with $9.3 \%$ of the springtime catch. Atlantic herring was the third most abundant fish by number ( 3,563 , or $9.0 \%$ of the total). Winter flounder and striped searobin were the third and fourth most abundant, respectively, for the spring. Windowpane flounder, historically one the top five most abundant species, was only the six most abundant species this season by number with 1,624 fish accounting for 265.8 kg . Summer flounder (fluke) springtime catches have been increasing since the mid 1990's, except for a dip in 2005-2006 (Table 2.18). The springtime fluke index was 3.24 fish/tow, roughly three times more than the time-series average of 1.4 fish/tow. An unusually high number of spot (shown to the right) were present not only in LISTS springtime catches but in catches reported by recreational anglers. Although spot have been documented in approximately $75 \%$ of our fall surveys, this is the first time spot have been observed during the spring survey. Spot were the eighth most common species seen during this
 Survey with 1,434 fish observed and a geometric mean of 0.89 fish/tow.

Overall, the number of finfish caught in spring of 2013 was lighter than typical in both numbers and biomass, yet the mean number of finfish species caught per sample ( 11.9 species) was similar to the spring time-series average of 11.4 species per sample (Figure 2.15). An open water forage abundance biomass index was calculated (see Methods section) using both the spring and fall biomass of the Sound's forage base. This index also reflected lighter than normal catch of forage species in 2013 (Figure 2.16). The 2013 forage base index of $6.85 \mathrm{~kg} / \mathrm{tow}$ was $50 \%$ less than the 1992-2013 average ( $14.09 \mathrm{~kg} /$ tow). Squid and butterfish dominate this index and their lower abundance in the Sound is the primary reason for the lower than average index value. The 2013 biomass of the three YOY species (bluefish, weakfish, and scup), which make up about a third of the forage index, was also low. However, the 2013 biomass index of Atlantic herring and menhaden was average, indicating that their availability in the Sound has not declined.

Additionally, a geometric mean weight per tow for aggregated finfish and aggregated invertebrates was calculated for the spring and fall time-series (Figure 2.17). The mean was calculated as described above for individual species but biomass was summed initially for each tow, first for finfish and then invertebrates. Mean biomass per tow of finfish was calculated as 38.09 kg per tow during the spring of 2013; about $21 \%$ below the 1992-2013 time series average of 48.26 kg per tow. Invertebrate biomass was quite low; a $61.4 \%$ decrease from the average of 8.06 kg per tow.

A total of 43,875 finfish weighing $6,131 \mathrm{~kg}$ were sampled in fall of 2013 (Table 2.16). Catches in the fall survey have consistently been dominated by four species: butterfish, scup, weakfish and bluefish (Table 2.16). In fact, three of the four (butterfish, scup and bluefish) have been the five most abundant fish in each fall survey in the LISTS time-series. In 2013, the four named species comprised $85.5 \%$ of the total catch of finfish and $47.8 \%$ of the total fall biomass. Butterfish comprised $59.0 \%$ of the fall catch by number and $16.9 \%$ by weight. The fall catch of 25,876 butterfish was about $65 \%$ below average in 2013, a significant decrease from fall 2012 and the fourth lowest in the time series (geometric mean catch per tow $=60.24$, Table 2.19, Figure 2.8). Scup abundance fell precipitously to about $23 \%$ of average fall levels with 7,924 fish $(1,255.0 \mathrm{~kg})$ taken or $18.1 \%$ of the fall total count and $20.5 \%$ of the fall biomass. The corresponding fall indices for all sizes of scup (40.68, Table 2.19) and for young-of-year scup (17.74, Table 2.23) were both well below their time-series means of 178.56 and 131.45, respectively (Figure 2.11). Weakfish and bluefish comprised $4.3 \%$ and $4.1 \%$ of the fall catch, with 1,876 fish and 1,809 fish, respectively. Bluefish abundance was at an all time low this past season with an index of 9.71 fish per tow. Overall, bluefish abundance has been trending lower since the peak of 45.3 fish per tow in 1999. The bluefish abundance index is typically driven by young-of-year fish which were noticeably absent from the September and October samples. The 2013 young-of-year bluefish index ( 7.86 fish/tow, Table 2.22) was $49 \%$ of the long term average and the second lowest since 1984. The weakfish index of abundance ( 7.5 fish/tow) again dropped to below average levels for the time-series (Table 2.19). Five out of the last six years have been below average for weakfish in Long Island Sound. Similar to bluefish, weakfish abundance is driven by the young-of year index ( $7.01 \mathrm{fish} /$ tow, Table 2.28). Over the timeseries, $97 \%$ of the fall weakfish catch has been young-of-year weakfish (less than 30 cm TL ). The fall age $1+$ index for weakfish ( 0.52 fish/tow), although lower than the previous two years, still remained $73 \%$ higher than average fall levels ( 0.30 fish/tow). The previous two fall surveys (2011 and 2012) had the most age 1+ weakfish since the peak catch in 1997 (Figure 2.13). Smooth dogfish again ranked high in biomass (2nd) with $1,507.1 \mathrm{~kg}$ from 758 individuals. Overall, the number of finfish caught in fall of 2013 was lighter than typical in both numbers and biomass, yet the mean number of finfish species caught per sample ( 13.6 species) was slightly above the 12.5 species per sample average (Figure 2.15). As described above, geometric means are calculated for finfish biomass per tow and, similar to the spring, finfish biomass per tow is about $22 \%$ less than average since 1992 (Figure 2.17). Invertebrate biomass per tow during the fall survey is 15.40 kg per tow or about $56 \%$ less than average.

A total of $1,947 \mathrm{~kg}$ of invertebrates were taken in 2013 (Table 2.15). Over $75 \%$ of the invertebrate biomass was comprised of four species, namely, blue mussel ( $622.1 \mathrm{~kg}, 31.9 \%$ of total), horseshoe crab ( $531.8 \mathrm{~kg}, 27.3 \%$ ), long-finned squid ( $170.8 \mathrm{~kg}, 8.8 \%$ ), and spider crab ( $156.5 \mathrm{~kg}, 8.0 \%$ ). The total biomass of invertebrate catch taken in the spring of 2013 was 644 kg (Table 2.17). Horseshoe crab had the highest biomass 269.2 kg comprising $41.6 \%$ of the total spring weight followed by spider crab with 130.6 kg ( $20.2 \%$ ) and long-finned squid with 35.3 kg (5.5\%). For American lobsters, the 2013 spring index of 0.44 lobsters/tow was the lowest recorded in the thirty year time series (Table 2.18). The spring 2013 index of long-finned squid (1.47 per tow) was also the lowest observed for the series (Table 2.18, Figure 2.14). Springtime squid abundance has dropped each year since 2009. A total of $1,303 \mathrm{~kg}$ of invertebrates were taken in fall of 2013 (Table 2.17). Blue mussel topped the fall list of invertebrate biomass, with 609.6 kg or $46.8 \%$ of the total invertebrate biomass for fall, however, the majority of the blue mussel catch occurred from only two tows last year. Horseshoe crab was the second most
abundant invertebrate with 262.6 kg or $20.2 \%$ of the biomass, followed by 10.4 kg of longfinned squid. Squid abundance was the third lowest for the time series ( 32.59 squid/tow) and comprised mostly of individuals less than 13 cm in length ( $96 \%$ ). There were only 24 American lobster ( 6.7 kg ), yielding an index of 0.16 lobsters per tow, another record low for fall abundance (Table 2.19, Figure 2.14).

The invasive alga species, Heterosiphonia japonica (HJ), was again documented in a significant number of springtime tows in 2013 ( $48 \%$ of the tows). A total springtime catch of 539.3 kg was recorded and the June survey had the highest monthly biomass, mostly because of a single large haul ( 245.8 kg ) off of the Mattituck sill. Fall samples, however, only had a $29 \%$ occurrence rate. The largest fall sample of 13.8 kg occurred at the mouth of the Thames River in October. HJ has been a significant nuisance for the trawl survey by increasing the time associated with clearing the net for the next set. Even small catches of this alga increase processing time because it does not shake out of the meshes easily. Large catches of this particular alga (see photo at right) likely decrease the performance of the net.

## Length Frequencies

Length frequency tables are provided primarily to give the reader an understanding of the size range of various species taken in LISTS. Lengths are converted to age frequencies for analysis of principal species such as scup, bluefish, striped bass, summer flounder, tautog, winter flounder, and weakfish. Changes such as an expansion in the size (age) range for some important recreational species are apparent in recent years including more large scup (Table 2.52-2.53), striped bass (Table 2.54-2.55), and summer flounder (Table 2.56-2.57).

Length frequencies were prepared for 22 species:
alewife
American shad
American lobster
Atlantic herring
Atlantic menhaden
black sea bass
blueback herring
bluefish
butterfish
clearnose skate
fourspot flounder

For the years where length data are available, length frequencies were prepared for the seasons or months for which the preferred indices of abundance and catch-at-age matrices are calculated; for some species length frequencies are provided for both seasons.

## Seasonal Indices of Abundance

The geometric mean count per tow was calculated from 1984-2013 for 38 finfish species plus lobster and long-finned squid (squid since 1986). All spring (April-June) and fall (September-October) data are used to compute the abundance indices presented in Tables 2.18 (spring) and 2.19 (fall), with the preferred seasonal index (for counts) denoted by an asterisk. Geometric mean biomass-per-tow indices have been calculated for 38 finfish and 15 invertebrate species (or species groups) since 1992, for both spring and fall (Table 2.20 and 2.21, respectively). Age specific indices of abundance were calculated for selected important recreational species, including scup, striped bass, summer flounder, and winter flounder (see below). For two other species, bluefish and weakfish recruitment indices were calculated using modal analysis of the length frequencies. For each of the thirty-eight finfish species, plots including catch per tow in numbers and biomass in kilograms are illustrated in Figures 2.8 through 2.13. These figures also include plots of each of the age specific indices and recruitment indices mentioned above. Figure 2.14 provides plots of abundance (biomass) indices for crabs (lady, rock, spider; 1992-2013), American lobster (1984-2013), horseshoe crab (1992-2013), and long-finned squid (1986-2013).

During the spring survey only two finfish species were at record high levels of abundance (black sea bass and spot). There were six species at record low levels during this past spring (American lobster, fourbeard rockling, ocean pout, sea raven, long-finned squid, and winter flounder). Of the species where the spring index is the preferred index of abundance for the trawl survey (Table 2.18), an additional five species had indices of abundance (geometric mean count per tow) at or above the time-series mean; alewife, Atlantic herring, spiny dogfish, striped bass, and winter skate (Figures $2.8-2.13$ ). Although the fall trawl index is usually the preferred index of scup abundance, even the springtime scup indices have mostly been above average since 2000 (Table 2.18) due to high abundances of age $2+$ scup in recent years (Figure 2.11). Similarly, the fall index is usually preferred for summer flounder, but over the last several seasons, spring catches have risen to levels comparable to the fall. The 2013 spring abundance of 3.24 fish/tow is the third highest index and is above the fall index of 3.07 fish/tow.

During the fall survey, only one species had record high abundance, smooth dogfish. Of the species where the fall index is the preferred index of abundance for the trawl survey (Table 2.19), an additional ten (10) species had indices of abundance (geometric mean count per tow) above the time-series mean; clearnose skate, spotted hake, hickory shad, hogchoker, moonfish, northern kingfish, rough scad, spot, striped searobin, and summer flounder (Figures $2.8-2.13$ ). Conversely, three species had record low indices of abundance; bluefish, blueback herring and American lobster (Table 2.19).

Relative indices of abundance (geometric mean number per tow) of American lobster were at record low levels for both spring and fall surveys in 2013. This continues the decreasing trend begun in the late 1990's. American lobster abundance in spring 2013 remains very low at 0.44 lobsters per tow (Table 2.18). Current springtime abundance is only about $2.5 \%$ of the peak abundance of 18.52 lobsters per tow seen in 1998 (Figure 2.14). In each of the past three fall surveys, the abundance index for American lobster has reached successively new record low levels and is currently less than $1 \%$ of peak abundance seen in the 1997 fall survey (19.60 lobsters per tow, Table 2.19). Catch of long-finned squid has been a bit below average for the past three years and the fall index is currently only the second lowest in the time-series ( 32.59 squid/tow) (Tables 2.18-2.19, Figure 2.14). Lady crab and rock crab indices have been low for the past decade, (Tables 2.20-2.21, Figure 2.14).

## Indices of Abundance: Important Recreational Species

Spring and fall abundance indices are presented in Tables 2.18-2.19. Indices of abundance at age were also calculated for seven important recreational species: bluefish (Table 2.22), scup (Table 2.23), striped bass (Table 2.24 age frequency, Table 2.25 indices at age), summer flounder (Table 2.26), tautog (Table 2.27), weakfish (Table 2.28) and winter flounder (Table 2.29). Bluefish and striped bass indices-at-age are based on the fall and spring surveys, respectively, whereas winter flounder indices-at-age are based on only the April and May cruises of the spring survey. In 2013, LISTS collected otoliths from 688 winter flounder, 685 of which were used in the development of age keys and the final catch-at-age matrix. Both scup and weakfish indices-at-age are calculated and presented separately for each season. Scales from 775 scup were collected and aged in 2013, 773 of which were used in the keys and calculations of the age matrix. Weakfish and bluefish use modal distributions for calculating their respective recruitment index although a small number of weakfish are taken each year for ageing purposes (see methods).

Although the striped bass abundance in spring recently fell below the time series mean from 2010-2012, the current index of 0.67 fish per tow increased modestly and remains well above the average for the first eight years of the time series ( 0.08 fish per tow, 1984-1992). Springtime adult scup abundance remains high relative to 1984-1999 levels; the 2013 spring index of age $2+$ fish ( 53.31 fish/tow) was the sixth highest in the time-series (Table 2.23, Figure 2.11). The index of age $2+$ in the fall ( 16.24 fish/tow) was average for the time series yet relatively high compared to the first half of the time-series average of 2.58 fish/tow. There was a unusual lack of young-of-year scup during the fall of 2013. The abundance abruptly dropped to levels not seen since the first four years of the survey when abundance was at a minimum. Summer flounder (fluke) abundance, in both spring and fall, has generally been increasing for the past 15 years (Tables 2.18-2.19). The fall index of abundance has historically been viewed
as the preferred index of abundance from the trawl survey, however, fluke are now just as abundant in the spring survey. The fluke index for spring 2013 ( 3.24 fish per tow) is more than double the time-series average ( 1.46 fish per tow) and the fall index ( 3.07 fish per tow) is the seventh highest in the time-series. The spring survey index for tautog has remained low and below the time-series average for 20 of the past 21 years, although there was a small, short-lived increase in abundance in 2002 (Table 2.18, Figure 2.13). Abundance indices from 1993-2013 averaged 0.48 fish/tow, only about half the 1984-1992 average of 1.2 fish/tow. Winter flounder springtime abundance (April-May, age4+) has been low and declining for the past twelve years, with 2006 being the lowest index for the time-series and the average for 2007-2013 being approximately one-third the time series average (Table 2.29, Figure 2.9).

A couple of other species of recreational importance were at relatively high abundances in 2013. Black sea bass indices for both spring and fall were record highs or near record levels for the LISTS time-series ( 0.97 fish per tow in the spring and 0.99 fish per tow in the fall, Tables 2.18-2.19). Spot, a popular recreational species further south along the East Coast, showed up in large numbers during the spring of 2013; having a record geometric mean of 0.89 fish per tow. Spot abundance during the fall was also high with at 1.7 fish per tow and was second only to the peak index of 2.67 fish/tow in 2008 (Table 2.19, Figure 2.12). Hickory shad abundance was also relatively high in the fall 2013 survey, with the forth highest index of the time-series $(0.16$ fish/tow) being much higher than the rest of the time-series except for $2005 \& 2006$ (Table 2.19, Figure 2.12). Finally, adult weakfish was also relatively abundant in the 2013 surveys; the 1+ spring index ( 0.52 fish per tow) was the second highest of the time-series, behind 2012 ( 0.62 fish per tow), while the $1+$ fall index (also 0.52 fish per tow) remained well above the time series mean ( 0.30 fish per tow) (Table 2.8, Figure 2.13).

## Winter Flounder Average Size at Maturity

Average size at maturity for winter flounder captured in April and May cruises has increased since maturation data recording began in 1990. The number mature by cm-interval and sex was calculated for the subset of fish examined in the laboratory each year, and a five-year average computed to maximize sample size. The resulting maturation curves (Figure 2.18) skew right for both sexes from 1990-94 to 2010-2013. The 50\%-midpoint for females has increased from 2426 cm in the 1990 s to 27 cm after 2000. The $50 \%$-midpoint for males has increased from 1619 cm in the 1990 s to $20-22 \mathrm{~cm}$ after 2000. These results indicate not only a larger average size at maturation but also a greater synchronization of the maturation process over a smaller size range.

## Species Richness by Group

The number of cold temperate and warm temperate species captured in each tow was averaged by seasonal cruise (April-June and September-October) for each year from 1984-2013 as an indicator of annual biological diversity or species richness. Trends in these indicators were tested for statistical significance by regression analysis. Results (Figure 2.19) show that the average number of warm temperate species captured/tow in spring and fall cruises has increased ( $\mathrm{F}=22.6$ and 64.0 respectively, $\mathrm{p}<0.001$ ); while the average number of cold temperate species has decreased, especially in spring ( $\mathrm{F}=22.9$, $\mathrm{p}<0.001$ ) but also in fall cruises ( $\mathrm{F}=8.6, \mathrm{p}=0.007$ ).

## MODIFICATIONS

Ecosystem health relates to the diversity of species and the abundance of numerous species (not just recreationally important species or forage species), yet the LIS Trawl Survey collects only minimal data for some of these other species (e.g. only count and weight are recorded). Therefore, in 2014, lengths will be collected from all finfish species on each tow. The same sub-sampling procedures will be employed for large catches as has been done in the past. To help offset the increase in time needed to process the catch (due to more species being measured), to handle an expanding number of sample requests, and to acquire age structures from additional species (bluefish and menhaden) as required by ASMFC fishery management plans, LISTS will no longer collect weakfish otoliths or process weakfish for ageing purposes. Connecticut has been de minimus status under the ASMFC weakfish fishery management plan for years and has minimal commercial ( $<5,000 \mathrm{lbs}$ ) and recreational (no MRIP intercepts since 2004) fisheries.

Table 2.1. Specifications for the Wilcox 14 m high-rise trawl net and associated gear.

| Component | Description |
| :--- | :--- |
| Headrope | 9.1 m long, 13 mm combination wire rope |
| Footrope | 14.0 m long, 13 mm combination wire rope |
| Sweep | Combination type, 9.5 mm chain in belly, 7.9 mm chain in wing |
| Floats | 7 floats, plastic, 203 mm diameter |
| Wings | 102 mm mesh, \#21 twisted nylon |
| Belly | 102 mm mesh, \#21 twisted nylon |
| Tail Piece | 76 mm mesh, \#21 twisted nylon |
| Codend | 51 mm mesh, \#54 braided nylon |
| Ground Wires | 18.2 m long, $6 \times 7$ wire, 9.5 mm diameter |
| Bridle Wires: | top legs 27.4 m long, $6 \times 7$ wire, 6.4 mm diameter |
| Bottom Legs | 27.4 m long, $6 \times 7$ wire, 11.1 mm, rubber disc type, 40 mm diameter |
| Doors | Steel "V" type, 1.2 m long x 0.8 m high, 91 kg |
| Tow Warp | $6 \times 7$ wire, 9.5 mm diameter |

Table 2.2. The number of sites scheduled for sampling each month within the 12 depth-bottom type strata.

|  | Depth Interval (m) |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Bottom type | $\mathbf{0 - 9 . 0}$ | $\mathbf{9 . 1 - 1 8 . 2}$ | $\mathbf{1 8 . 3 - \mathbf { 2 7 . 3 }}$ | $\mathbf{2 7 . 4 +}$ | Totals |
| Mud | 2 | 3 | 5 | 5 | 15 |
| Sand | 2 | 2 | 2 | 2 | 8 |
| Transitional | 3 | 5 | 5 | 4 | 17 |
| Totals | $\mathbf{7}$ | $\mathbf{1 0}$ | $\mathbf{1 2}$ | $\mathbf{1 1}$ | $\mathbf{4 0}$ |

Table 2.3. Length and age data collected in 2013.
In addition to the species listed below, other rarely occurring species (totaling less than 30 fish/year each) were measured. During 2013, twenty-six other species were measured during LISTS sampling as either rarely occurring species or for other research related projects

| Species measured | Measurement | \# tows/day | \# fish measured |
| :---: | :---: | :---: | :---: |
| Alewife | FL (cm) | All | min of 15 / tow |
| American lobster | CL ( 0.1 mm ) | All | min of $50 /$ tow |
| American shad | FL (cm) | All | min of 15 / tow |
| Atlantic herring | FL (cm) | All | min of 15 YOY and min of 30 adults / tow |
| Atlantic menhaden | FL (cm) | All | min of 15 / tow |
| Atlantic sturgeon | FL (cm) | All | All |
| Blueback herring | FL (cm) | All | min of $15 /$ tow |
| Bluefish | FL (cm) | All | min of 30 YOY / tow, all adults |
| black sea bass | TL (cm) | All | All |
| butterfish | FL cm) | 1st -3rd | min of 15 YOY and 15 adults / tow |
| cunner | TL (cm) | All | All |
| dogfish, smooth | FL (cm) | All | All |
| dogfish, spiny | FL (cm) | All | All |
| fourspot flounder | TL (cm) | 3 rd on | min of $30 /$ tow |
| hake, red | TL (cm) | 3 rd on | min of $30 /$ tow |
| hake, silver (whiting) | TL (cm) | 3 rd on | min of $30 /$ tow |
| hake, spotted | TL (cm) | 3 rd on | min of $30 /$ tow |
| hickory shad | FL (cm) | All | All |
| horseshoe crab | PW (cm) | All | All |
| northern searobin | FL (cm) | 3 rd on | min of 30/tow |
| moonfish | FL (cm) | Occasional | min of $10 /$ tow |
| smallmouth flounder | TL (cm) | Occasional | min of $10 /$ tow |
| striped bass | FL (cm) | All | All |
| striped searobin | FL (cm) | 3 rd on | min of $30 /$ tow |
| scup | FL (cm) | All | min of 15 YOY and $30 /$ mode for age $1+$ |
| long-finned squid | ML (cm) | 1st -3rd | min of $30 /$ tow |
| summer flounder | FL (cm) | All | All |
| tautog | TL (cm) | All | All |
| weakfish | FL (cm) | All | min of $15 \mathrm{YOY} /$ tow, all adults |
| whelk, channeled | PW (mm) | All | All |
| whelk, knobbed | PW (mm) | All | All |
| windowpane flounder | TL (cm) | 1st -3rd | min of 50 / tow |
| winter flounder | TL (cm) | All | min of $100 /$ tow |
| winter skate | TL (cm) | All | All |
| Species aged | Structure | Subsample |  |
| bluefish | scales / otoliths | Collected each season. For each season, minimum of 50 scale and otolith samples collected from full length distribution. Spring collection may use other means of sampling to obtain the required minimum. |  |
| Menhaden | scales | Collected ea length distrib minimum. | r each season, minimum of 30 scale samples collected from full tion may use commercial sampling to obtain the required |
| scup | scales | Collected ev $<20 \mathrm{~cm}$; 5/c | or each month scales are taken from the following: 3 fish/cm cm ; and all fish > 30 cm . |
| summer flounder | scales | all fish $>=6$ |  |
| tautog | opercular bones | Collected fro | of 200 fish/year. |
| weakfish | scales / otoliths | Collected ea and all scale | r each season, 1 scale and one otolith sample / cm up to 19 cm $>=20 \mathrm{~cm}$. Ageing/collections discontinued in October 2014 |
| winter flounder | otoliths | Collected du <br> For each mo <br> fish / cm < 3 <br> $\mathrm{cm}<30 \mathrm{~cm}$, | May from two areas in the Sound: eastern-central and western. subsamples are taken as follows: in the eastern-central area 7 from $30-36 \mathrm{~cm}$, all fish $>36 \mathrm{~cm}$. In the western area 5 fish / $30-36 \mathrm{~cm}$, all fish > than 36 cm . |

Notes: $\min =$ minimum; YOY = young-of-year; $\mathrm{FL}=$ fork length; $\mathrm{TL}=$ total length; $\mathrm{CL}=$ carapace length; $\mathrm{ML}=$ mantle length; $\mathrm{PW}=$ prosomal width.

Table 2.4. Number of Long Island Sound Trawl Survey (LISTS) samples taken by year and cruise.
In 1984, thirty-five sites per monthly cruise from April through November were scheduled for sampling. Starting in 1985, forty sites per cruise were scheduled. In 1991, the Trawl Survey was modified to a spring (April - June) and fall (September - October) format--July, August and November sampling was suspended. In 1993 and 1994 , an additional cruise of 40 sites was added to the fall period. The additional fall cruise was suspended in 1995. One hundred twenty tows were conducted in 2006 due to delays in rebuilding the main engine on the R/V John Dempsey (spring) and mechanical failure/overhaul of the hydraulic power take-off (fall). Delays in overhauling the transmission in the fall of 2008 resulted in missing September sampling. The June cruise and all of fall sampling in 2010 were canceled for an engine replacement in the $R / V$ John Dempsey. Due to delays in engine replacement, begun in 2010 but not completed until late April 2011, April sampling in 2011 was abbreviated.

| Cruise | ${ }^{\prime} 1984$ | ${ }^{\prime} 1985$ | $1986$ | $1987$ | $1988$ | $1989$ | $1990$ | $1991$ | ${ }_{1992}$ | $1993$ | $1994$ | ${ }^{\prime} 1995$ | ${ }^{1996}$ | $1997$ | $\begin{array}{r} Y e \\ \\ \hline 1998 \\ \hline \end{array}$ | $\begin{aligned} & \text { ear } \\ & { }_{1}{ }^{2999} \\ & \hline \end{aligned}$ | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | Total |

Job 2 Page 27

Table 2.8. Station information for LISTS September 2013.
Standard LISTS tows in the spring begin with SP and fall begins with FA. Latitude (N) and Longitude ( $W$ ) are displayed in decimal degrees. Surface and bottom temperature and salinity are labeled as $S_{-}$and $B_{-}$, respectively. Area swept is estimated by assuming the effective sweep is $2 / 3$ rds of the footrope length.

| Sample <br> Number | Date | Site <br> Number | Bottom Type | Depth Interval | Time Start | Duration (min) | Latitude | Longitude | $\begin{gathered} \text { S_Temp } \\ (\mathbf{s f c}, \mathbf{C}) \end{gathered}$ | S_Salinity (sfc, ppt) | $\begin{gathered} \hline \text { B_Temp } \\ \text { (btm, C) } \end{gathered}$ | $\begin{gathered} \text { B_Salinity } \\ \text { (btm, ppt) } \end{gathered}$ | Ave Speed (knots) | Distance (nm) | Area Swept (sq.nm) |

Job 2 Page 28

Table 2.9. Station information for LISTS October 2013.
Standard LISTS tows in the spring begin with SP and fall begins with FA. Latitude (N) and Longitude ( $W$ ) are displayed in decimal degrees. Surface and bottom temperature and salinity are labeled as $S_{-}$and $B_{-}$, respectively. Area swept is estimated by assuming the effective sweep is $2 / 3$ rds of the footrope length

| Sample <br> Number | Date | Site <br> Number | Bottom Type | Depth Interval | Time <br> Start | $\begin{gathered} \text { Duration } \\ (\min ) \end{gathered}$ | Latitude | Longitude | $\begin{gathered} \hline \text { S_Temp } \\ (\mathrm{sfc}, \mathrm{C}) \end{gathered}$ | S_Salinity (sfc, ppt) | B_Temp <br> (btm, C) | B_Salinity (btm, ppt) | Ave Speed (knots) | $\begin{gathered} \text { Distance } \\ (\mathbf{n m}) \end{gathered}$ | Area Swept (sq.nm) |

Job 2 Page 29

Table 2.10. Samples with non-standard tow durations and reasons for incomplete tows, spring and fall 2013.
Standard LISTS tows begin with SP(spring) or FA (fall).

| Sample | Date | Site | Bottom Type | Depth <br> Interval | Time | Duration | Reason | Comments |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| APRIL |  |  |  |  |  |  |  |  |
| SP2013027 | 4/17/2013 | 5709 | S | 2 | 12:01 | 25 | pots | pot gear with expired tags |
| SP2013029 | 4/18/2013 | 0614 | M | 2 | 8:19 | 22 | pots | single pot with expired tags in net; lots of growth on pot |
| MAY |  |  |  |  |  |  |  |  |
| SP2013046 | 5/9/2013 | 5709 | S | 2 | 11:44 | 16 | pots | snagged string of active pots set across our path; also 2 single pots in net, one had 2012 tag and one had no tag |
| SP2013050 | 5/10/2013 | 0114 | M | 4 | 10:37 | 17 | pots | 2 attempts; strings of old gear on both attempts |
| SP2013052 | 5/10/2013 | 0218 | M | 4 | 13:50 | 22 | pots | 2 attempts; strings of old gear on both attempts; some damage to net |
| SP2013057 | 5/14/2013 | 0720 | M | 3 | 12:57 | 23 | pots | string of active gear; no buoy visible - was shrunken and submerged |
| SP2013066 | 5/16/2013 | 0226 | T | 2 | 12:32 | 20 | algae | net clogged with algae |
| SP2013075 | 5/20/2013 | 1029 | S | 3 | 15:16 | 28 | speed drop | speed dropped just before boost but no gear or debris in net |
| JUNE |  |  |  |  |  |  |  |  |
| SP2013091 | 6/17/2013 | 0629 | S | 4 | 14:53 | 28 | weather | had to leave area due to rapidly approaching thunderstorm |
| SP2013092 | 6/18/2013 | 0627 | S | 3 | 8:31 | 22 | pots | pot buoys in our lane; ran out of room to tow |
| SP2013097 | 6/19/2013 | 0823 | M | 3 | 9:53 | 25 | pots | string of pot gear on door |
| SP2013105 | 6/20/2013 | 0218 | M | 4 | 13:20 | 21 | pots | string of ghost pots; net badly torn |
| SP2013110 | 6/25/2013 | 0511 | M | 2 | 8:48 | 24 | pots | string of old gear on door |
| SP2013115 | 6/26/2013 | 0413 | M | 3 | 11:32 | 24 | pots | string of pot gear on door, expired tags |
| SP2013116 | 6/26/2013 | 0514 | M | 2 | 12:52 | 16 | pots | multiple strings of gear; expired tags |
| SEPT |  |  |  |  |  |  |  |  |
| FA2013015 | 9/12/2013 | 1433 | S | 2 | 7:15 | 25 | hang | came off during haul-back; no damage to net |
| FA2013020 | 9/13/2013 | 0418 | M | 4 | 8:27 | 20 | hang | came off during haul-back; no damage to net |
| FA2013026 | 9/16/2013 | 0320 | M | 4 | 13:32 | 22 | pots | string of pots; large tear in net |
| FA2013036 | 9/19/2013 | 0015 | T | 4 | 15:00 | 17 | pots | snagged multiple strings of pot gear, some active but tags expired; some inactive; lots of strain on net; line in prop; damage to net nneded repair |
| OCT |  |  |  |  |  |  |  |  |
| FA2013043 | 10/8/2013 | 1840 | T | 1 | 10:46 | 22 | pots | single ghost pots net; some had expired tags, others had no tags; some pots broken up |
| FA2013046 | 10/15/2013 | 0731 | S | 4 | 8:01 | 25 | speed drop | speed dropped but no gear or debris in net; sand dunes? |
| FA2013064 | 10/21/2013 | 0110 | T | 3 | 10:19 | 28 | hang | large rocks in net; repaired damage to chain/foot rope |
| FA2013069 | 10/22/2013 | 0015 | T | 4 | 11:51 | 20 | pots | gear on both doors |
| FA2013076 | 10/30/2013 | 1221 | T | 2 | 8:10 | 20 | pots | pot buoys in our lane; ran out of room to tow; also one ghost pot in net (expired tags; escape vent released); mended holes in net |
| FA2013079 | 10/30/2013 | 1224 | T | 2 | 12:06 | 21 | hang | came off during haul-back; no damage to net |

Table 2.13. List of finfish species observed in 2013.
Fifty - five finfish species were observed in 2013. (Bold type indicates new species). Since 1984, one hundred-four species of finfish have been identified in LISTS (see Appendix 2.1 for the full list of species).

| Common Name | Scientific Name | Common Name | Scientific Name |
| :---: | :---: | :---: | :---: |
| anchovy, bay | Anchoa mitchilli | menhaden, Atlantic | Brevoortia tyrannus |
| anchovy, striped | Anchoa hepsetus | moonfish | Selene setapinnis |
| black sea bass | Centropristes striata | pipefish, northern | Syngnathus fuscus |
| bluefish | Pomatomus saltatrix | pollock | Pollachius virens |
| butterfish | Peprilus triacanthus | puffer, northern | Sphoeroides maculatus |
| cornetfish, red | Fistularia petimba | ray, bullnose ray | Myliobatis freminvillei |
| croaker, Atlantic | Micropogonias undulatus | rockling, fourbeard | Enchelyopus cimbrius |
| cunner | Tautogolabrus adspersus | sand lance, American | Ammodytes americanus |
| dogfish, smooth | Mustelus canis | scad, rough | Trachurus lathami |
| dogfish, spiny | Squalus acanthius | scad, round | Decapterus punctatus |
| eel, conger | Conger oceanicus | sculpin, longhorn | Myoxocephalus octodecemspin |
| flounder, fourspot | Paralichthys oblongus | scup | Stenotomus chrysops |
| flounder, smallmouth | Etropus microstomus | searobin, northern | Prionotus carolinus |
| flounder, summer | Paralichthys dentatus | searobin, striped | Prionotus evolans |
| flounder, windowpane | Scophthalmus aquosus | shad, American | Alosa sapidissima |
| flounder, winter | Pseudopleuronectes american | shad, hickory | Alosa mediocris |
| glasseye snapper | Priacanthus cruentatus | silverside, Atlantic | Menidia menidia |
| goatfish, red | Mullus auratus | skate, clearnose | Raja eglanteria |
| haddock | Melanogrammus aeglefinus | skate, little | Leucoraja erinacea |
| hake, red | Urophycis chuss | skate, winter | Leucoraja ocellata |
| hake, silver | Merluccius bilinearis | spot | Leiostomus xanthurus |
| hake, spotted | Urophycis regia | stargazer, northern | Astroscopus guttatus |
| harvestfish | Peprilus paru | striped bass | Morone saxatilis |
| herring, Atlantic | Clupea harengus | sturgeon, Atlantic | Acipenser oxyrinchus |
| herring, alewife | Alosa pseudoharengus | tautog | Tautoga onitis |
| herring, blueback | Alosa aestivalis | toadfish, oyster | Opsanus tau |
| hogchoker | Trinectes maculatus | weakfish | Cynoscion regalis |
| kingfish, northern | Menticirrhus saxatilis |  |  |

Names taken from: Common and Scientific Names of Fishes from the United States, Canada and Mexico, American Fisheries Society, Sixth ed., 2004.

Table 2.14. List of invertebrates observed in 2013.
In 2013, forty-one invertebrate" species" were identified. In most cases, invertebrates are identified to species; however, species that are very similar are identified to genus, and in difficult cases, to a higher taxon.

| Common Name | Scientific Name | Common Name | Scientific Name |
| :--- | :--- | :--- | :--- |
| Tubularia hydroids | Tubularia, spp. | northern moon snail | Lunatia heros |
| arks | Noetia-Anadara spp. | oyster, common | Crassostrea virginica |
| bryozoan, bushy | Phylum Bryozoa | sea cucumber | Class Holothuroidea |
| bryozoan, rubbery | Alcyonidium verrilli | sea grape | Molgula spp. |
| clam, hard clams | Artica-Mercinaria-Pitar sp. | sea urchin, purple | Arbacia punctulata |
| clam, surf | Spisula solidissima | shrimp, coastal mud | Upogebia affinis |
| coral, star | Astrangia poculata | shrimp, ghost | Gilvossius setimanus |
| crab, mud | Family Xanthidae | shrimp, mantis | Squilla empusa |
| crab, Japanese shore | Hemigrapsus sanguineus | shrimp, northern red | Pandalus montagui |
| crab, blue | Callinectes sapidus | shrimp, sand | Crangon septemspinosa |
| crab, flat claw hermit | Pagurus pollicaris | sponge spp. | Crepidula fornicata |
| crab, horseshoe | Limulus polyphemus | sponge, boring | sponge spp. |
| crab, lady | Ovalipes ocellatus | sponge, deadman's fingers | Haliclona spp. |
| crab, rock | Cancer irroratus | sponge, red bearded | Microciona prolifera |
| crab, spider | Libinia emarginata | squid, long-finned | Loligo pealeii |
| hydroid spp. | hydroid spp. | starfish spp. | Asteriid spp. |
| jelly, comb | Phylum Ctenophora | whelk, knobbed | Busycotypus canaliculatus |
| jellyfish, lion's mane | worms, fan | Busycon carica |  |
| lobster, American | Cyanea capillata | Myxicola infundibulum |  |
| mussel, blue | Homarus americanus | Mytilus edulis | Geukensia demissa |

Names taken from: A Field Guide to the Atlantic Seashore, Peterson Field Guide Series, 1978 (Gosner, 1978).

Table 2.15. Total number and weight (kg) of finfish and invertebrates caught in 2013.
Finfish species are in order of descending count. Invertebrate species are in order of descending weight (nc $=$ not counted). Young-of-year bay and striped anchovy are neither separated by species or quantified; young-of-year Atlantic herring and American sand lance are not quantified. Number of tows (sample size)=200.

| species | count | \% | weight | \% | species | count | \% | weight | \% |

Table 2.18. Spring indices of abundance for selected species, 1984-2013.
The geometric mean count per tow was calculated for 38 finfish and 2 invertebrates using April-June data. An asterisk next to the species name and time series mean, indicates that the spring index is a better estimate than the fall index (Simpson et al. 1991). Two asterisks indicate that both the spring and the fall indices provide good estimates.

## Table 2.19. Fall indices of abundance for selected species, 1984-2013.

The geometric mean count per tow was calculated for 38 finfish and 2 invertebrates using September-October data. An asterisk next to the species name and a time series mean, indicates that the fall index provides a better estimate than the spring index (Simpson et al. 1991). Two asterisks indicate that both the spring and the fall indices provide good estimates. There was no fall sampling in 2010.

Table 2.20. Finfish and invertebrate biomass indices for the spring sampling period, 1992-2013.
The geometric mean weight (kg) per tow was calculated for 38 finfish and 15 invertebrate species for the spring (April-June) sampling period.

|  | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 2.21. Finfish and invertebrate biomass indices for the fall sampling period, 1992-2013.
The geometric mean weight (kg) per tow was calculated for 38 finfish and 15 invertebrate species for the fall (Sept-Oct) sampling period. There was no fall sampling in 2010.

|  | Fall |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 2.22. Bluefish indices of abundance, 1984-2013.
Using September and October length data, the geometric mean catch per tow was calculated for two age groups of bluefish: age-0 and all fish age 1 and older. Age-0 was defined as bluefish less than 30 cm fork length.

Job 2 Page 42

Table 2.23. Scup indices-at-age, 1984-2013.
Spring (May and June) and fall (September and October) catch and age data were used to determine the geometric mean indices-at-age ${ }^{1}$. The spring and fall age keys were used to expand length frequencies to age frequencies and then the spring and fall overall indices were proportioned by the percentage of fish in each age. The 0-10+ index represents the overall index (sum of ages $0-10+$ ), and the adult $2+$ index is provided as the sum of ages $2-10+$ index. Fish older than age 9 were included in the age 10+ index ${ }^{2}$.

| Year | Spring (May-June) |  |  |  |  |  |  |  |  |  |  |  |  |

(1) In 1984, 1985, 2003, 2004, 2006, 2008,2010 and 2011 less than the number of scheduled tows were conducted in some months (Table 2.4).
(2) Fish in the age 10+ group include: 6 fish taken 1984-1988, 8 fish taken 2002-2010, 81 taken in 2011, 28 taken in 2012, and 26 taken in 2013. The oldest scup aged were two 14-year-old fish taken in 1985 and 2013.

Table 2.24. Age frequency of striped bass taken in spring, 1984-2013.
Ages were derived from trawl survey length data using the average of Hudson River and Chesapeake Bay von Bertalanffy parameters.

| Year |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Note: number of fish taken but not measured = one in 1984, one in 1988, two in 1990.

Table 2.25. Striped bass indices-at-age, 1984-2013.
Spring length data was converted to ages using the average of Hudson River and Chesapeake Bay von Bertalanffy parameters (Vic Crecco, pers comm). Indices-at-age were then determined by apportioning the spring indices (from Table 2.10) by the percentage of fish in each age.

|  |  | Spring |  |  |  |  |  |  |  |  |  |  |  |

Table 2.26. Summer flounder indices-at-age, 1984-2013.
Year and season specific age keys obtained from the NMFS spring and fall surveys were used to convert LISTS length frequencies to ages. Starting in 2000 LISTS ageing data ( 60 cm and over) were added to the age key to supplement the older age groups. Indices-at-age were determined for each season by apportioning the spring and fall overall indices (from Table 2.19 and Table 2.20) by the percentage of fish in each age.

| Year | 0-11 | Age 0 | Age 1 | Age 2 | Age 3 | Spring <br> Age 4 | Age 5 | Age 6 | Age 7 | Age 8 | Age 9 | Age 10 | Age 11 |

Table 2.27. Tautog indices-at-age, 1984-2013.
Year and season specific age keys obtained from the LISTS spring and fall surveys were used to convert LISTS length frequencies to ages. Indices-at-age were then determined for each season by apportioning the spring and fall overall indices (from Table 2.10 and Table 2.11) by the percentage of fish in each age, and then summing the spring and fall indices-at-age. The age 1-20+ index is the sum of indices ages $1-20+$. The age 20+ category includes 36 fish ranging from 20 to 30 years of age.

| Year | Age |  |  |  |  |  |  |  |  |  |  |

[^0]Table 2.28. Weakfish age 0 and age $1+$ indices of abundance, 1984-2013.
Using spring (May, June) and fall (September, October) length data, the geometric mean catch per tow was calculated for three groups of weakfish: fall age-0, spring - all fish age 1 and older (1+), and fall - all fish age 1 and older $(1+)$. Weakfish less than 30 cm fork length in the fall were defined as age-0.

| Year | Fall |  | Fall |  | Spring |  |

Table 2.29. Winter flounder indices-at-age, 1984-2013.
The Long Island Sound Trawl Survey April and May catch and age data was used to calculate the geometric mean indices-at-age. An April-May age key was used to convert lengths to ages, and an overall April-May index (the ages 1-13 index in the table) was apportioned by the percentage of fish at age. The 4+ index is the sum of indices ages 4-13 and represents the abundance of winter flounder that are recruited to the fishery. The age-0 indices were obtained from the Estuarine Seine Survey (Job 2 Part 2).

Note: 1984: April = 0 tows, May = 13 tows, and 19 tows in June used to increase sample size; 1985: April = 0 tows, May = 41 tows; 1986-1991, 1993-1995,
1997-2004, 2009, and 2012-2013: April = 40 tows, May $=40$ tows; 1992 and 2006: April $=0$ tows, May = 40; 1996: April = 17 tows, May $=63$ tows; 2005:
April $=35$ tows, May $=45$ tows; 2007: April $=35$ tows, May $=45$ tows; 2008: April $=36$, and May $=44$ tows; 2010: May $=38$ tows, $2011:$ April $=12$ tows.

TABLES 2.30-2.65 LENGTH FREQUENCIES

LISTS

Job 2 Page 49

Table 2.30. Alewife length frequencies, spring and fall, $1 \mathbf{c m}$ intervals, 1989-2013.
From 1989-1990, lengths were recorded from the first three tows of each day; since 1991, lengths have been recorded from every tow.

| length | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Job 2 Page 50

Table 2.31. American shad length frequencies, spring and fall, 2.0 cm intervals (midpoint given), 1989-2013.
From 1989-1990, lengths were recorded from the first three tows of each day; since 1991, lengths have been recorded from every tow.

| length | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 2.33. American lobster length frequencies-fall, female, 1 mm intervals, 1984-2013.
Lobsters were measured from each tow.

Table 2.34. American lobster length frequencies-spring, male, 1 mm intervals, 1984-2013.
Lobsters were measured from each tow.

| Male | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 2.35. American lobster length frequencies-fall, male, 1 mm intervals, 1984-2013.
Lobsters were measured from each tow.

| Male <br> Length | Fall |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 2.36. Atlantic herring length frequencies, spring and fall, 1 cm intervals, 1989-2013.
Atlantic herring lengths were recorded from the first three tows of each day.

| length | 1989 | 1990 | 1991 | 1992 | 1993 | 1994 | 1995 | 1996 | 1997 | 1998 | $1999$ | ${ }_{2000} \begin{gathered}\text { Spring } \\ 2001\end{gathered}$ |  | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 |

Table 2.37. Atlantic menhaden length frequency, spring and fall, $1 \mathbf{c m}$ intervals, 1996-2013.
Menhaden are scheduled to be measured from every tow. However, the following numbers of menhaden were not measured: 5 juveniles and 4 adults in 1996, and 7 adults in 1997.

| Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Job 2 Page 58

Table 2.39. Black sea bass length frequencies, fall, 1 cm intervals, 1987-2013.
Since 1987, black sea bass have been measured from every tow.

| length | Fall |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 2.40. Blueback herring length frequencies, spring and fall, 1 cm intervals, 1989-2013.
From 1989-1990, lengths were recorded from the first three tows of each day; since 1991, lengths have been recorded from every tow.

Table 2.43. Butterfish length frequencies, 1 cm intervals, spring and fall, 1986-1990, 1992-2013.
Length frequencies of butterfish taken from the first three tows of each day.

| length | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 2.46. Fourspot flounder length frequencies, spring and fall, 2 cm intervals (midpoint given), 1989, 1990, 19962013.

Fourspot lengths were recorded from the first three tows of each day.

Table 2.47. Hickory shad length frequencies, spring and fall, 1 cm intervals, 1991-2013.
Hickory shad were measured from every tow, with the exception of one fish in each of fall 1996, fall 1997, and fall 1998.

Table 2.48. Horseshoe crab length frequencies by sex, spring, 1 cm intervals, 1998-2013.
Horseshoe crabs were measured (prosomal width) from every tow.

Table 2.51. Long-finned squid length frequencies, fall, 1 cm intervals, 1986-1990, 1992-2013.
Length frequencies of squid taken from the first three tows of each day.

| length | 1986 | 1987 | 1988 | 1989 | 1990 | 1992 | 1993 | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | Fall 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 |

Table 2.54. Striped bass spring length frequencies, 2 cm intervals (midpoint given), 1984-2013.
All striped bass taken in the Survey were measured, with the exception of one fish taken in 1984, one in 1988, and two in 1990.

Job 2 Page 84

Table 2.65. Winter skate length frequencies, spring and fall, 2 cm intervals (midpoint given), 1995-2013.
Winter skate were scheduled to be measured from every tow. However, the following numbers of skate were not measured: 4 in 1995, 10 in 1996, and 2 in 1997.

FIGURES 2.1-2.19 LISTS

Figure 2.1. Trawl Survey site grid. Each sampling site is $1 x 2 \mathrm{nmi}$ (nautical miles). A four-digit number identifies the site: the first two digits are the row numbers (corresponding to minutes of latitude) and the last two digits are the column numbers (corresponding to two nautical miles in length on the longitudinal axis). Examples: site 1428 near Guilford and 0028 near Mattituck. (Note: The sites in column 16 are approximately $2 x 1$ nmi. The grid was drawn on the Eastern and Western Long Island Sound 80,000:1 nautical charts, which overlap by the area in column 16.)

Figure 2.2. April 2013 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Samples collected from a different site than published in the "Notice to Fishermen" are noted in table below map.

| Sample | Site <br> Sampled | Sampled Strata | Site Selected | Selected Strata | Reason Moved |
| :---: | :---: | :---: | :---: | :---: | :---: |

Figure 2.3. May 2013 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Samples collected from a different site than published in the "Notice to Fishermen" are noted in table below map.

| Sample | Site <br> Sampled | Sampled Strata | Site Selected | Selected Strata |
| :---: | :---: | :---: | :---: | :---: | Reason Moved |  |
| :--- |
| No sites were moved during this cruise. |

Figure 2.4. June 2013 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Samples collected from a different site than published in the "Notice to Fishermen" are noted in table below map.

Job 2 Page 91

Figure 2.5. September 2013 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Samples collected from a different site than published in the "Notice to Fishermen" are noted in table below map.

Job 2 Page 92

Figure 2.6. October 2013 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Samples collected from a different site than published in the "Notice to Fishermen" are noted in table below map.

| Sample | Site <br> Sampled | Sampled Strata | Site Selected | Selected Strata |
| :---: | :---: | :---: | :---: | :---: | Reason Moved $\quad$.

Figure 2.7. Number of finfish species observed annually, 1984-2013. Note: there was no October sampling in 2006 and there was no June, September or October sampling in 2010. Average number of finfish species caught per year is 57.5 for the time-series. See Table 2.4 for details on number of tows completed each year.

Figure 2.8. Plots of abundance indices for: black sea bass, bluefish (total, age 0, and ages $1+$ ), butterfish, cunner, and dogfish (smooth and spiny).

Legend:

$$
\begin{aligned}
\text { ■ } & =\text { count } / \text { tow } \\
& =\mathrm{kg} / \text { tow } \\
---- & =\text { mean count } / \text { tow }
\end{aligned}
$$

Figure 2.9. Plots of abundance indices for: flounders (fourspot, summer, windowpane, winter, and winter ages 4+) and hakes (red, silver, and spotted).

Legend:

$$
\begin{aligned}
\square & =\text { count } / \text { tow } \\
\boldsymbol{\Delta} & =\mathrm{kg} / \text { tow } \\
---- & =\text { mean count } / \text { tow }
\end{aligned}
$$

Figure 2.10. Plots of abundance indices for: herrings (alewife, Atlantic, and blueback), hogchoker, Northern kingfish, Atlantic menhaden, moonfish, and ocean pout.

Figure 2.11. Plots of abundance indices for: fourbeard rockling, rough scad, longhorn sculpin, sea raven, and scup (all ages, age 0, and ages 2+).

Legend:

$$
\begin{aligned}
\square & =\text { count } / \text { tow } \\
\boldsymbol{\Delta} & =\mathrm{kg} / \text { tow } \\
--- & =\text { mean count } / \text { tow }
\end{aligned}
$$

Figure 2.12. Plots of abundance indices for: searobins (striped and northern), shad (American and hickory), skates (clearnose, little, and winter), and spot.

Legend:

$$
\begin{aligned}
\square & =\text { count } / \text { tow } \\
\boldsymbol{\Delta} & =\mathrm{kg} / \text { tow } \\
--- & =\text { mean count } / \text { tow }
\end{aligned}
$$

Figure 2.13 Plots of abundance indices for: striped bass, Atlantic sturgeon, tautog, and weakfish (all ages, age 0, and ages 1+).

Legend:

$$
\begin{aligned}
\square & =\text { count } / \text { tow } \\
\Delta & =\mathrm{kg} / \text { tow } \\
--- & =\text { mean count } / \text { tow }
\end{aligned}
$$

Figure 2.14. Plots of abundance and biomass indices for: crabs (lady, rock, and spider), horseshoe crab, American lobster, and long-finned squid.

Legend for bottom four graphs:

$$
\begin{aligned}
\square & =\text { count } / \text { tow } \\
\boldsymbol{\Delta} & =\mathrm{kg} / \text { tow } \\
--- & =\text { mean count } / \text { tow }
\end{aligned}
$$

Figure 2.15. Mean number of finfish species per sample, spring and fall, 1984-2013. This index measures the diversity of species supported within the Sound's various habitats.

Figure 2.16. Open water forage abundance, 1992-2013. The geometric mean is calculated as the aggregate sample biomass per tow of 14 of the most common forage species sampled in the survey. This index measures the available food base which supports both resident and migratory species. The average since 1992 is $14.09 \mathrm{~kg} / \mathrm{tow}$ (red line).

Figure 2.17. Geometric mean biomass of finfish and invertebrates per sample, spring and fall, 1992-2013. This index measures the diversity of species supported within the Sound's various habitats.

Figure 2.18: Percent of sampled winter flounder that were sexually mature by length group for female and male flounder captured in LISTS over five time periods, 1990-2013.

Figure 2.19. Trends in the number of cold temperate versus warm temperate species per sample captured in spring and fall LIS Trawl Surveys. See Appendix 2.5 for list of species included in analysis.

## APPENDICES

LISTS

Appendix 2.1. List of finfish species identified by A Study of Marine Recreational Fisheries in Connecticut (F54R) and other CT DEP Marine Fisheries Division programs. LISTS has collected one hundred-four finfish species from 1984-2013.
This appendix contains a list of 146 species identified (Bold type indicates new species) from all sampling programs conducted since 1984. Species are listed alphabetically by common name (AFS 2004). Sampling program abbreviations, survey time periods and gear type are as follows:

| Survey Abbreviation | Survey Description | Time Period | Gear Type |
| :---: | :---: | :---: | :---: |
| CTR | CT River Creel Survey | 1997-1998 | bus stop creel survey mainstem of CT River |
| EPA | cooperative sampling in western LIS with EPA | 1986-1990 | used LISTS net |
| ESS (F54R) | Estuarine Seine Survey | 1988 to present | 7.6 m ( 25 ft ) beach seine |
| IS (F54R) | Inshore Survey of Juvenile Winter Flounder | 1990-1994 | beam trawls (also a little data from 1995-1996) |
| ISS (F54R-starting 2008) | Inshore Seine Surveys in CT \& TH rivers | 1979 to present | $15.2 \mathrm{~m}(50 \mathrm{ft})$ bag seine set by boat |
| LISTS (F54R) | Long Island Sound Trawl Survey | 1984 to present | $14 \mathrm{~m}(50 \mathrm{ft}$ ) trawls with 2 " codend mesh |
| MISC | misc sampling conducted on R/V Dempsey | various | various |
| NCA | "inshore" EPA NCA C2K sampling | 2000 | skiff trawls |
| NRRWS | sampling in western end of LIS, the "Narrows" | 2000-2007 | $14 \mathrm{~m}(50 \mathrm{ft}$ ) trawls with 2 " codend mesh |
| SNFH (F54R) | Study of Nearshore Finfish Habitat | 1995-1996 | plankton net |
| SS (F54R) | Summer Survey | 1991-1993, 1996 | 14 m ( 50 ft ) trawls with codend liner in LIS |
| TN | Trap Net Survey | 1997-1998 | trap nets in rivers |
| Common Name | Scientific Name | Survey |  |

## Appendix 2.2. Annual total count of finfish, lobster and squid taken in the LISTS, 1984-2013.

Counts include all tows- number of tows conducted shown in second row. Refer to Appendix 2.4 for details on number of tows conducted per month. Note: nc $=$ not counted. Anchove spp., (yoy) and sand lance, (yoy) are estimated.

| Common name (number of tows) | $\begin{array}{r} 1984 \\ 200 \\ \hline \end{array}$ | 1985 246 | 1986 316 | $\begin{array}{r} 1987 \\ 320 \\ \hline \end{array}$ | $\begin{array}{r} 1988 \\ 320 \\ \hline \end{array}$ | $\begin{array}{r} 1989 \\ 320 \\ \hline \end{array}$ | $\begin{array}{r} 1990 \\ 297 \\ \hline \end{array}$ | $\begin{array}{r} 1991 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} 1992 \\ 160 \\ \hline \end{array}$ | $\begin{array}{r} 1993 \\ 240 \\ \hline \end{array}$ | $\begin{array}{r} 1994 \\ 240 \\ \hline \end{array}$ | $\begin{array}{r} 1995 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} 1996 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} 1997 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} 1998 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} 1999 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} 2000 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} \mathbf{2 0 0 1} \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} 2002 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} 2003 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} 2004 \\ 199 \\ \hline \end{array}$ | $\begin{array}{r} 2005 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} 2006 \\ 120 \\ \hline \end{array}$ | $\begin{array}{r} 2007 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} \mathbf{2 0 0 8} \\ 120 \\ \hline \end{array}$ | $\begin{array}{r} 2009 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} 2010 \\ 78 \\ \hline \end{array}$ | $\begin{array}{r} 2011 \\ 172 \\ \hline \end{array}$ | $\begin{array}{r} 2012 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} 2013 \\ 200 \\ \hline \end{array}$ | $\begin{array}{r} \text { Total } \\ \mathbf{6 , 3 4 8} \\ \hline \end{array}$ |

## Appendix 2.4. cont. Total number and weight (kg) of finfish and invertebrates caught in LISTS in 2006.

Finfish species are in order of descending count. Invertebrate species are in order of descending weight (nc $=$ not counted). Young-of-year bay and striped anchovy are neither separated by species or quantified; young-of-year Atlantic herring and American sand lance are not quantified. Number of tows (sample size)=120.

## Appendix 2.4. cont. Total number and weight (kg) of finfish and invertebrates caught in 2009.

Finfish species are in order of descending count. Invertebrate species are in order of descending weight (nc $=$ not counted). Young-of-year bay and striped anchovy are neither separated by species or quantified; young-of-year Atlantic herring and American sand lance are not quantified. Number of tows (sample size)=200.

Appendix 2.4. cont. Total number and weight (kg) of finfish and invertebrates caught in 2013.
Finfish species are in order of descending count. Invertebrate species are in order of descending weight (nc = not counted). Young-of-year bay and striped anchovy are neither separated by species or quantified; young-of-year Atlantic herring and American sand lance are not quantified. Number of tows (sample size)=200.

Appendix 2.5: Endangered Species Interactions: Four (4) Atlantic sturgeon were captured on three of the 200 tows completed in 2013. This yields a lower encounter rate $(1.5 \%)$ than the average for the LISTS time series ( $2.4 \%$ ). Two of the three tows occurred over transition bottom type, while the other occurred over sand bottom type. All three tows were in the 18.3-27.3m ( $60-90 \mathrm{ft}$ ) depth interval. All individuals were released alive and uninjured. Each sturgeon received a T-bar tag in the base of the left pectoral fin and were scanned for passive integrated transponders (PIT). Since no PITs were detected, a PIT was inserted near the base of each dorsal fin. All captures were reported to NMFS within 24 hours. Details for each fish are provided below:

Job 2 Page 147

Appendix 2.6: Cold and warm temperate species captured in LISTS. Thirty-three (33) species are included in the cold temperate group, while thirty-four (34) species are included in the warm temperate group. Cold temperate species are defined as being more abundant north of Cape Cod, MA than south of New York, behaviorally adapted to cold temperatures including subfreezing but prefers $\sim 3-15^{\circ} \mathrm{C}$, and spawns at lower end of temperature tolerance. Warm temperate species are defined as being more abundant south of New York than north of Cape Cod, MA, behaviorally avoids temperatures $<7-10^{\circ} \mathrm{C}$; prefers $\sim 11-22^{\circ} \mathrm{C}$, and spawns at higher end of temperature tolerance.

## JOB 2 PART 2: ESTUARINE SEINE SURVEY

## OBJECTIVES

1) Provide an annual index of recruitment for winter flounder (Age0, 1+), all finfsh species taken, and all crab species.

The 2013 annual index of recruitment for young-of-year winter flounder ( 0.275 fish/haul) ranked the lowest out of 26 annual indices.
2) Provide an annual total count for all finfish taken.

Mean catch of all finfish (140 fish/haul) ranked fourteenth highest out of 26 annual indices and was slightly below the series average of 147 fish/haul (Figure 2.2). Geometric means were calculated for 22 species commonly captured since the survey began in 1988 (Table 2.1).

## 3) Provide an index for shallow subtidal forage species abundance.

An index of forage abundance was generated using the catch of four of the most common forage species caught: Atlantic silversides, striped killifish, mummichog, and sheepshead minnow. The index for 2013 ( 46 forage fish/haul) was the fourth lowest of the 26-year series, and well below the time series average of 97 forage fish/haul.

## METHODS

Eight sites (Figure 2.1) are sampled during September using an eight-meter ( 25 ft .) bag seine with 6.4 mm ( 0.25 in .) bar mesh. Area swept is standardized to 4.6 m ( 15 ft .), width by means of a taut spreader rope and a 30 m ( 98 ft .), measured distance, parallel to, or at a $45^{\circ}$ angle to the shoreline, against the current or tide if present. At each site, six seine hauls are taken within two hours before and after low slack tide during daylight hours. Sites in Groton, Waterford, Old Lyme, Clinton, New Haven, Bridgeport and Greenwich have been sampled since 1988. The Milford site was added in 1990. In addition to September sampling, the original seven sites were sampled in June, July, and August 2013 to compare with samples taken in these months in 1988-1990. Sampling methods were the same as described above.

Finfish, crabs, and other invertebrates taken in each sample are identified to species or lowest practical taxon (full listing given in Appendix 2.1, 2.2) and counted. One exception is inland silversides, which are not separated from Atlantic silversides because they are rare and difficult to identify. Qualitative counts were used for menhaden when abundant ( $\mathrm{n}>1000$ ) to minimize discard mortality. Winter flounder are measured to total length ( mm ), and classified as young-of-year (YOY) if less than 12 cm and age $1+$ if 12 cm or larger. The age of flounder near this size was verified in 1990-1992 by examination of the sagittal otolith. Physical data recorded at each seine location included water temperature and salinity at one-meter depth. The geometric or retransformed natural $\log$ mean catch per standard haul is calculated for catches at each site and
collectively for the 22 most abundant species, with separate indices for young-of-year and winter flounder age 1 and older. Confidence intervals ( $95 \%$ ) for each geometric mean are retransformations of the corresponding log intervals. Frequency of occurrence is given as a percentage of all samples taken each year.

Diversity in the catch, or species richness, was computed for finish species captured in the Survey over the time series. Species were divided into three groups based on their temperature preferences and seasonal spawning habits as documented in the literature (Collette and Klein-MacPhee 2002, Murdy et al. 1997). Criteria used to assign species into a cold temperate group, warm temperate group, or subtropical group are listed in Job 2.1.

## RESULTS

A total of 48 seine hauls were taken in 2013 at eight sites, yielding a total catch of 6,704 fish of 26 species and 13,490 invertebrates of eleven species. Mean catch of all finfish ( 140 fish/tow) was the twelfth lowest in the 26 year time series (Figure 2.2). This catch is slightly below the long-term mean of 147 fish/tow which can be attributed to below average catches of all forage fish species. Atlantic silversides were caught in average abundance. All other forage fish abundances were below average.

Geometric means were calculated for 22 species commonly captured since the survey began in 1988 (Table 2.1). The most frequently caught species was Atlantic silversides, which occurred in all samples, followed by northern pipefish ( $60 \%$ ), black sea bass (58\%), striped killifish (58\%), northern puffer (38\%), northern kingfish (35\%), blackfish (33\%), smallmouth flounder (29\%) and mummichog (27\%). This rank order has changed from the previous years, with a notable decrease in winter flounder (age 0 and age $1+$ ), mummichog, striped killifish, grubby and windowpane flounder occurrence rates and an increase in black sea bass, northern pipefish, northern puffer and northern kingfish occurrence. Ten of the 22 species monitored decreased in abundance in 2013, nine other fish species increased slightly and three were unchanged. Tautog abundance and occurrence rate decreased significantly in 2013. Tautog abundance and occurrence rate increased significantly in 1998-99, returned to the series average in 2005, 2010 and 2011 after a record year in 2007. Previous to 2005, tautog relative abundance significantly increased to all-time abundance levels in 2002-04 and 2012 (Figure 2.4). The abundance of cunner the other labridae species commonly seen in the survey fell in 2011 and 2013 but rebounded above the time series averages in 2012 after declining in abundance since 2007.

In 2013, all four of the forage species monitored decreased in abundance from the previous year (Atlantic silverside, especially mummichog and striped killifish). Forage fish species Atlantic silverside was slightly below the 26 year time-series average in 2013. Scup occurrence and abundance decreased below the 26 year time series average in 2013, but increased to its largest abundance in 3 years in 2012, which is the second largest abundance overall. Snapper bluefish occurred in the time series in 2011, 2012 and
again in 2013 after a 2007 absence. Striped bass and weakfish were not observed in the survey in 2013. Weakfish young-of-year were absent and only occurred in 2003. All other species occurred in less than $10 \%$ of all samples, with occurrence rates similar to previous years.

Butterfish (Peprilus triacanthus) a pelagic forage species, occurred for the second time in the time series. Striped Burrfish (Chilomycterus schoepfi) a member of the porcupinefish family re-occurred in 2013, was also present in 2011 and 1999. Seven juvenile summer flounder were captured in 2013. Summer flounder (juvenile) have also occurred in 200608 and 2010 of the 26 year time series. Windowpane flounder re-occurred at low abundance in 2011 after being absent in 2009-10 and 2012-13. Other notable catches: at the Waterford site; lined seahorse, spot, and oyster toadfish along with inshore lizardfish. The Cinton site saw large numbers of YOY black sea bass, butterfish, pipefish, northern puffer and summer flounder. The Greenwich site saw YOY winter founder along with forage species Atlantic silverside and striped killifish. The New Haven site saw many black sea bass and northern kingfish. Summer flounder, northern kingfish, snapper bluefish, striped burrfish and large numbers of forage species were captured at the Old Lyme site. Bridgeport saw the lowest species diversity with Atlantic silverside being common. The Groton (Bluff Point) site saw large numbers of YOY black sea bass, along with YOY winter flounder, grubby and sheepshead minnow.

## Relative Abundance of Juvenile Winter Flounder and Tautog

The 2013 index of YOY winter flounder ( 0.275 fish/haul) ranked lowest out of the 26 annual indices (Table 2.2, Figure 2.3 and 2.7). Overall, the time series indicates that relatively strong year classes were only produced many years ago in 1988, 1992, 1994, and 1996 (Figure 2.3).

The 2013 index of YOY tautog ( 0.6 fish/haul) was the thirteenth highest ranking out of 26 annual indices (Table 2.1, Figure 2.4), slightly below the series average of 0.7 tautog / haul. Overall, the time series indicates an increasing trend in abundance of young-ofyear tautog from 1988 to 2008, with relatively abundant year classes produced in 199899, 2002-04, 2007-08 and 2012. The 2006, 2009-11 and 2013 mean was below the longterm average. $(\mathrm{P} \leq 0.05, \mathrm{t}=2.3, \mathrm{df}=25)$, (Table 2.1, Figure 2.4).

## Presence of Other Important Recreational Finfish

YOY scup is a recent addition to the seine survey. The species occurred in 1999, with the highest relative abundance in the last ten years of the time series. In 2013, the species was present in low numbers, reflecting poor recruitment and survival for the species in 2013 (Table 2.3, Figure 2.7). Juvenile striped bass first occurred in the survey in 1999 with one individual captured. In 2003, six more YOY striped bass were taken (Table 2.3, Figure 2.8). One large individual ( 369 mm ) was captured in 2008. YOY summer flounder have occurred in eleven years (more recently) in the 26-year time series (1993, 1994, 1996, and 1998, 2006 - 2010, 2012-13). The 2006 summer flounder abundances
were the highest of the time series, followed by 2007, 2008, 2010 and 2012. No summer flounder were captured in 2011. YOY black sea bass first appeared in 1991 and every year since 1997, reaching their record highest abundance in 2013 (Figure 2.7). Snapper bluefish occurred in 20 out of 26 years of the time series, reaching peak abundance in 1999. Juvenile tautog occurred every year in the seine survey except 1989. White perch appeared in record numbers in 2008 and only once prior, (2005) were present in 2011, and absent in 2012-13. Atlantic tomcod, a threatened species re-appeared in 2008 and 2011, none were present in 2009, 2010 and 2012-13. Inshore lizardfish were captured at average abundances for the time series in 2013. Fourspine stickleback were absent in 2012-13, and appear to be dropping out of the survey, occurring only 4 times in the past decade.

## Relative Abundance of Forage Species

Seine survey catches are numerically dominated by forage species, defined here as shortlived, highly fecund species that spend the majority of their life cycle inshore where they are common food items for piscivorous fish. An index of forage fish abundance was generated using the catch of four of the most common forage species caught: Atlantic silversides, striped killifish, mummichog, and sheepshead minnow (Figure 2.5, Figure 2.6). The index for 2013 was the fourth lowest in the 26 year time series. All of the four forage fish species decreased in abundance and occurrence in 2013. Atlantic silverside abundance declined in 2013 ( 45 fish /haul) and was below the series mean of 65 fish/haul for the time series (Table 2.1). Atlantic silversides were the most abundant, and the only species present at all sites in all samples (Table 2.1). There was a substantial decrease in striped killifish, and mummichog abundance in 2013. A decrease in these species' abundance in 2012-13 reversed a five-year trend of increasing abundance from 20072011. Striped killifish decreased substantially in abundance in 2013, to the ninth lowest in the time series. This species of killifish abundance and occurrence (3.8fish/tow, 58\% occurrence) was well below the series mean of 10.08 fish/tow. In 2013, mummichog abundance ( 0.9 fish/haul) was also well below the long-term average of 2.35 in 2013. Sheepshead minnow had record abundance (3.35) in 2007 and decreased in 2008 through 2010 and 2013. Sheepshead increased slightly in 2011 and again in 2012, the index of abundance of this forage fish ( 0.2 fish/haul) was substantially lower, ranking fourteenth in the time series. Collectively, forage fish abundance has declined since 2003 (Figure 2.5).

Forage fish abundance had show a general increase since 1997 (Figure 2.5) after a period of lower abundance (decreasing trend) from 1991-1996. In 2013, forage fish abundance was below the series mean of $97 \mathrm{fish} / \mathrm{haul}$, with a mean catch of 46 fish per haul (large decline from 2007). Forage fish abundance is driven numerically by the occurrence of adult Atlantic silverside (Figure 2.6) and more recently striped killifish, mummichog and sheepshead minnow, the second, third and fourth most abundant forage species. Striped killifish are more suited to marine habitats, than other 'Fundulus' species captured in the estuarine seine survey. Striped killifish were captured at extremely low numbers in 201213 , suggesting very poor year class production and survival $2-3$ years ago, since the survey captures adults more effectively. Mummichog, the third most abundant forage fish (Table 2.3) in the survey, peaked in abundance in 2007. The lowest time series abundance occurred in 1997. Mummichog appeared to be stable with an above average
catches since 1999 but are more recently declining in abundance. Sheepshead minnow the least abundant of the four forage fish species monitored has recently shown elevated abundances in 2002-04 and 2007-09, with a record year in 2007 ( 3.35 fish/tow) and above average catches in 2008 ( 1.2 fish/tow) followed by slight decreases in 2009 and 2010. In 2011 and 2012, the sheepshead minnow catch rebounded and was slightly above the series average. The 2013 mean catch was 0.2 fish per tow, well below the series mean of 0.5 fish/tow.

## Comparison of 2013 Summer Samples with 1988-1990

A total of 42 seine hauls (six hauls at seven sites) were taken in June, July, and August 2013. Mean catch of all finfish at the seven sites varied from 17.0-50.1 fish/sample in June and July, respectively, to 92.3-82.4, respectively, in August and September. This seasonal pattern was similar to the pattern seen in 1988-1990 (June= 35.0, July= 44.6, August $=114.0$, September $=100.7$ fish $/$ sample) with lowest abundance in June and peak abundance in August. This seasonal progression probably reflects resident and migrant species moving into the nursery grounds and/or recruiting to the mesh size of the sampling gear. Standard errors for these monthly mean values (CV range of 19-39\%) make them statistically indistinguishable with the exception of the low value in June 2013.

In contrast to the seasonal increase in abundance seen in total finfish from June through September, winter flounder YOY abundance was highest in June and declined linearly over the summer (Figure X1). Although a seasonal decline in abundance was also noted in June-September of 1988-1990 (slope $=-0.13, \mathrm{r}^{2}=0.53$ ), the slope of the decline in 2013 was more than three times as steep (slope $=-0.42, \mathrm{r}^{2}=0.99$ ).

## Finfish Species Richness

Over the time series, the mean number of cold temperate species captured per seine haul (Figure 2.10, Table 2.4) varied from 1.6 to 2.8 with a slight negative trend ( $\mathrm{F}=4.6$, $\mathrm{p}=0.043, \mathrm{r}^{2}=0.12$ ) while the mean number of warm temperate species increased significantly ( $\mathrm{F}=32.3, \mathrm{p}<0.001, \mathrm{r}^{2}=0.56$ ). The mean number of warm temperate species increased from about 3 species/haul to almost 5 over the 25 -year time series. Subtropical species richness showed no trend, averaging about one species per haul almost every year.

## Relative Abundance of Invertebrate Species

A total of 13,490 invertebrates of eleven species were captured in 2013 (Table 2.3), (Appendix 2.2). Seven crab species were present in the seine hauls, along with two shrimp species and one gastropod. Mud snail, sand shrimp, shore shrimp, green crab, and hermit crab were the most abundant. Mud snails, shore shrimp, sand shrimp, and hermit crab had greater than $50 \%$ occurrence in 2013 (Table 2.3). Blue crab abundance continued to remain low in 2013 from an all-time high in 2009 ( 333 crabs). The Asian shore crab (Japanese crab) re-appeared in 2011 and 2012 but were absent from 2008-10 and 2013. Both sand and shore shrimp increased substantially in abundance in 2013 from the previous year (Table 2.3). Mud snail abundance was above the time series average. Mud crabs reached an all-time high abundance in 2013 after dropping in 2011 and 2012 from a high abundance in 2010. Spider crab abundance was at a time-series high in 2011 and increased slightly above the time series average in 2013.

## MODIFICATIONS

In 2014 the seven original seine sites (all sites except Milford) will be sampled in June, July, and August as well as September. These catch data will be compared to catches made in the same summer months in 1988-1990.

## JOB 3: AMERICAN SHAD MONITORING AND INSHORE SEINE SURVEYS

## STUDY PERIOD AND AREA

This report contains information on adult American shad monitoring and seine studies on juvenile American shad, blueback herring, menhaden and common nearshore marine species in 2013. Areas of the Connecticut River sampled range from Holyoke, MA to Essex, CT. The Thames River seine survey begins just south of Norwich Harbor and ends in Uncasville, CT. Time series data collected under a previous funding source are also included.

## GOAL

To monitor relative abundance and distribution of American shad and other fish in Connecticut's nearshore waters.

## OBJECTIVES

Provide:

1) Information on the adult American shad spawning population: commercial catch, age structure, sex ratio and size.
2) Annual indices of relative abundance for juvenile shad, blueback herring and common nearshore marine species.

## INTRODUCTION

Annual spawning migrations of American shad (Alosa sapidissima) in the Connecticut River have supported both recreational and commercial fisheries in the State of Connecticut, as well as recreational fisheries in upriver states, for generations. There is currently a commercial driftnet fishery that occurs in the lower Connecticut River. Connecticut requires an annual commercial shad license for the Connecticut River. The fishery is managed through area, gear, and season restriction as well as rest days. The Connecticut River is the state's only occurrence of a commercial shad fishery. American shad were once one of Connecticut's top five most economically important commercial finfish species in terms of landings. The commercial fishery occurs in the main stem of the Connecticut River south of the Putnam Bridge in Glastonbury, CT. The recreational fishery occurs north of Hartford, CT at River Kilometer (RKM) 83 and south of the Holyoke Dam in Massachusetts (RKM 139).

The Connecticut Department of Energy and Environmental Protection (CT DEEP) has conducted annual research studies on adult American shad in the CT River since 1974, to monitor annual changes in stock composition. Data are collected from mandatory annual reporting of commercial landings. Landings information is compiled and used to estimate the maximum losses to the spawning stock from fishing. The Massachusetts Division of Fish and Wildlife monitors fish passage which includes adult American shad passage at the first main stem dam on the CT River in Holyoke, Massachusetts. Data on the recreational fisheries are monitored periodically by a roving creel survey. Juvenile shad are monitored by CT DEEP through an
annual seine survey conducted since 1978. Sampling was expanded to the Thames River system after 1996 to monitor the effect of the operation of the Greenville Dam fish lift on anadromous fish restoration. The fish lift was constructed to aid in the enhancement of American shad and river herring in the system. CT DEEP initiated the seine survey in the Thames River to estimate juvenile production of shad and blueback herring. Sites were chosen based on previous work conducted by the department. The survey has documented few juvenile shad and river herring, but has been continued to monitor catches of forage fish and juvenile fish of recreationally important species such as menhaden, tautog, winter flounder and bluefish.

## METHODS

American shad adults
Commercial fishermen are required by regulation to report daily landings and fishing effort for American shad annually to CT DEEP. Landings information was compiled and used to estimate the maximum losses to the spawning stock from fishing. Harvest was tallied by pounds and number of shad landed by sex.

The adult American shad age structure and sex ratio were calculated from samples collected at the Holyoke Dam Fish lift, located at river kilometer 140, in Holyoke, MA. Information on the number of fish lifted daily, the number of lift days (days the lift is in operation) and the daily sex ratio at Holyoke were obtained from the Massachusetts Division of Fisheries. The annual sex ratio was calculated by weighting the daily sex ratios by the number of fish lifted daily. A daily subset of fish lifted are sampled for scales.

To estimate the age structure of the fishery, in past years CT DEEP staff have collected biological samples with drift gill nets with a mesh size similar to the commercial fishery and in a similar fashion to that used by commercial operators to assist in characterizing the fishery. Gill nets were fished during daylight hours to avoid interfering with commercial efforts; research nets were shorter in length and drift times were shorter than those employed by commercial netters. Fifty one scale samples were collected. No samples were collected in 2013 and future drift net collection effort will be minimal since it is not a requirement of the sustainability plan mandated by Amendment 3 to the Atlantic States Marine Fisheries Commission (ASMFC) American Shad Fishery Management Plan. Amendment 3 calls for system specific Sustainable Fishery Plans. The Sustainable Fishery Plan for the Connecticut River utilizes juvenile recruitment, Holyoke lift numbers (as a proxy for run size) and total commercial harvest to monitor stock health. Age composition obtained from gillnet collections will continue only if needed to serve coast-wide stock assessment needs.

Age structure of the CT River population was derived from scale samples collected at the Holyoke Fish lift in Holyoke, MA to characterize the population independent of the commercial fishery. Adult shad were sexed, measured to fork length (mm) and $15-25$ scales removed. All scale samples collected were separated by sex and stratified into 1 cm length groups. Scale samples were processed by cleaning with an ultrasonic cleaner and pressed onto acetate for aging. Age determinations were made as the consensus of two or more readers of projected images (43x) counting annuli and spawning scars according to the criteria of Cating (1953).

Repeat spawners were noted by the presence of spawning scar(s) at the periphery of the scale. The age and repeat spawning frequency were extrapolated to the annual lift count by direct proportion.

## Juvenile Surveys: <br> Connecticut River Seine Survey

A single seine haul was conducted at seven fixed locations one day a week from July 17th through October 16th, 2013. Seine haul locations and techniques were identical to those used in past Connecticut River seine surveys. The sampling sites were previously chosen based on location, physical conditions and accessibility (Marcy 2004, Crecco et. al. 1981, Savoy and Shake 1993). The seven stations were sampled during daylight hours with an 18.3 m nylon bag seine ( 0.5 cm delta mesh) and 30.5 m lead ropes. The seine was fished with the aid of a boat to deploy it upstream and offshore to sweep down through the site. Using the lead ropes, the seine was towed in a downstream arc to the shore and beached. All fish species other than family clupeidae, (Alosa sapidissima, A. aestivalis, A. pseudoharengus, and Brevoortia tyrannus) were identified, quantified or estimated and released. Invertebrate species are either counted or noted as present.

## Thames River Seine Survey

Eight fixed stations were sampled twice a month from July 12th through September 6th. The method of seine deployment and gear used in the Thames River was identical to that used for the Connecticut River seine survey.

For both surveys, clupeids (American shad, blueback herring, alewife and menhaden) were returned to the laboratory for measurement and identification. In the laboratory, juvenile clupeids were identified to species by the criteria of Lippson and Moran (1974) and counted. For each sample, up to 40 randomly selected clupeids of each species were measured to total length (mm).

A relative abundance index was calculated as a geometric mean catch per unit effort for both shad and blueback herring. Geometric mean is the preferred method when reporting to ASMFC for annual compliance reports because it normalizes clustered data. See Job 2, part 1 (Gottschall and Pacileo 2013) for methods used to calculate the geometric mean.

## RESULTS

## Commercial Fishery Landings

The Connecticut River American shad commercial fishery took 76,825 fish in 2013 which was a decline from the 2012 landings, and an increase from 2010 and 2011 (Figure 3.1). The 2013 commercial harvest ranked $20^{\text {th }}$ out of 24 years, demonstrating that landings continue to have a small impact on the total stock. The catch is reported as pounds and was converted to numbers of fish by sex (Table 3.1). Fifteen commercial shad licenses were sold in 2013, a number licenses comparable to recent years (Table 3.1, Figure 3.2). Shad landings appear consistent with the
fluctuations of passage at the Holyoke fish lift (Figure 3.3), which supports the assertion that the lift numbers represent a consistent percentage of the annual shad spawning stock in the Connecticut River.

Five boats reported landings in 2013. The number of shad boats fishing annually continues to remain low as few new participants enter the fishery (Figure 3.4). Some shad fishermen continue to purchase the license even if they have not actively fished in several years.

Commercial shad catch reports were skewed towards females ( $89 \%$ ), with males accounting for $11 \%$ of the reported landings (Table 3.1). Males are probably underreported, or less represented in the catch due to mesh size selectivity, or a combination of the two factors. Male shad are less valuable to sell to markets. Repeat spawning rates were not calculated due to the small sample size. Scale samples in the lower river were collected by Marine Fisheries staff in 2012 (Table 3.2) but not collected in 2013 due to staffing shortages.

## Connecticut River Adult American shad

The Holyoke Fish lift was open for fish passage from April 1 through July 17, 2013 except for closings due to high water or operational factors. Total lift numbers of American shad at the Holyoke Dam were obtained from the Massachusetts Division of Fisheries and Wildlife. The number of shad passed at Holyoke in $2013(392,967)$ was the 7th highest value since (Figure 3.3). The number of American shad lifted upstream annually at the Holyoke Dam has been highly variable through the time series, however 2013 was well above the long term mean of 304,000 (median $=289,000$, range 117,000 to 720,000 ).

The 2013 shad run sex ratio was derived from information collected at the Holyoke fish lift which is located at River Kilometer 140, upstream of both the commercial and sport fisheries. The combined impact of these small fisheries is likely not significant enough to affect the composition of the run. The weighted sex ratio of shad sampled at Holyoke was $48 \%$ male and $52 \%$ female (Figure 3.5).

American shad scales ( $\mathrm{n}=577$ ) were collected on 32 days over a 68 day span during lift operation. The shad age structure from scale samples was expanded based on the number of fish lifted at Holyoke Dam. Scales successfully aged totaled 565 ( 307 females and 257 males).

Length frequency of American shad collected at the Holyoke lift ranged from 32.5 to 48.0 cm FL for male shad and 37.5 to 53.0 cm FL among female shad. Length frequencies of both sexes were fairly normally distributed (Figures 3.5 and 3.6). Average size among males was 40.7 cm FL and among females was 46.9 cm FL .

The 2013 male population of spawning adult shad was produced from the 2007-2010 year classes. A large percentage ( $43.2 \%$ ) of male shad scales examined were from five year old fish, while $25 \%$ were from 4 year old fish and $25 \%$ were 6 year old fish. Three and seven year old fish represented $7 \%$ and $0.4 \%$ of the population, respectively (Table 3.3).

The majority of female shad ( $60 \%$ ) sampled in 2013 were six year old fish from the 2007 year class. Five year old fish contributed to $35 \%$ of the 2013 run and $3 \%$ were both four and seven year old fish. The incidence of overall repeat spawning remains low. The percentage of repeat spawners was $13.6 \%$ for males and $7.5 \%$ among females, with an overall repeat spawn rate of $10.3 \%$ (Table 3.3). The shad spawning population continues to rely on a few age classes and low rates of repeat spawners.

## Seine Survey

Juvenile collections in the Connecticut River were conducted from July 17th through October 16th, 2013. A total of 938 juvenile American shad were collected for the season (Table 3.4). The highest catch in 2013 was 159 shad collected at the Wilson site (RKM 89) in early September, representing $59 \%$ of the total Wilson catch for the season and $17 \%$ of the overall catch (Table 3.4). The station with the largest proportion of the season's catch was Wilson. Collectively, stations Wilson, Deep River, Salmon River and Glastonbury, accounted for $78 \%$ of the total 2013 catch. A total of 6,943 blueback herring were collected in 2013 (Table 3.5).

The geometric mean CPUE for shad in 2013 was nearly the same as 2012 and ranks as the 7th lowest in the time series (Table 3.6). The annual index of juvenile abundance (geometric mean catch/haul) has varied without trend over the time series. The geometric mean CPUE for blueback herring was slightly more than double that of American shad.

In the 91 hauls completed in 2013, over 16,000 fish representing 30 species or taxonomic groups were collected (Table 3.7). To minimize mortality and to facilitate returning large catches of fish quickly to the water, some fish were identified only to the family or genus level (e.g. sunfish, catfish, killifish). Large catches of common species were sometimes quantified with a visual estimate to minimize handling and processing time. Estimated catches are noted as such in the database. In 2013, the most abundant species collected were shiners (mixed species), blueback herring, Fundulus spp. and sunfish, followed by American shad ranking $5^{\text {th }}$ highest in total catch. Spottail shiners, American shad, Fundulus spp. and sunfish also had a high frequency of occurrence in the catches (Table 3.7).

Environmental conditions, as monitored by USGS (Figures 3.7 and 3.8), were quite variable in the upper river in 2013. Daily discharge values fluctuated widely and were often well above median gage height values that have been measured for the last 85 years in the Thompsonville stretch of the Connecticut River.

The ratio of blueback catches to shad varied seasonally in 2013 (Figure 3.9) and has been widely variable through the time series (Figure 3.10). In 2011 and 2012, shad catches exceeded blueback catches in the time series. Early in the time series, blueback catches would far exceed those of American shad. The 2013 Alosa spp. CPUE indices were both well below average. However, the blueback geometric mean CPUE is the 18th lowest, which ranks in the middle of the time series.

Annual catches of American shad by station over time has been variable with Holyoke and Wilson typically being the sites with the largest annual catches of juvenile shad (Figure 3.11). The Enfield and Essex sites provided the lowest catches of the season. The Enfield station produced the highest number of zero catches and lowest catch of the season. The Salmon River site ranks as the highest total catch for blueback herring, with $42 \%$ of the season's catch. The single highest seine haul of bluebacks was at Salmon River on August 7th (848) but was only $12 \%$ of the season's total catch of blueback herring (Figure 3.12). The geometric mean catch of juvenile American shad from all stations and all dates was 3.16 (Figure 3.12).

## Thames River Seine Survey

The 2013 Thames River survey was conducted bi-weekly from May 30th through October $10^{\text {th }}$ with 76 seine hauls. Over 14,000 fish were collected representing 45 groups or species (Table 3.8). Atlantic silversides had the highest presence in the catch ( $75 \%$ ), followed by Fundulus spp, bluefish and striped bass. Other notable species caught were: Winter flounder, striped bass, scup, snapper bluefish, and tautog. A few unique catches in 2013 included striped mullet and oyster toadfish.

Over the length of the time series, menhaden catches have had a wide variation ranging from an all time low in 2013 of just 31 fish, to over a million fish collected in 2000. The 2013 menhaden index, geometric mean CPUE of 0.14, ranked lowest out of 16 years (Table 3.9). Juvenile menhaden catches have been variable with the second lowest CPUE in 2010 (0.18) and a peak geometric mean CPUE of 117.46 in 2002.

## Data Requests and Sample Collections

Data requests and sample requests are fulfilled for a number of different government and nongovernment organizations. Six requests were fulfilled in 2013 (Table 3.10).

## MODIFICATIONS

No modifications are expected.

JOB 5: 2013 Long Island Sound Hypoxia Season Review

MONITORING LONG ISLAND SOUND 2013

2013 Long Island Sound
Hypoxia Season Review

## MONITORING LONG ISLAND SOUND 2013

## Program Overview

Since 1991, the Connecticut Department of Energy \& Environmental Protection (CT DEEP, formerly the Department of Environmental Protection, (CTDEP)) has conducted an intensive year-round water quality monitoring program on Long Island Sound (LIS). Water quality is monitored at up to forty-eight (48) sites by staff aboard the Department's Research Vessel John Dempsey.

R/V John Dempsey

These data are used to quantify and identify annual trends and differences in water quality parameters relevant to hypoxia, especially nutrients, temperature, and chlorophyll. These data are also used to evaluate the effectiveness of the management program to reduce nitrogen concentrations. During the summer (June -September) CT DEEP conducts additional summer hypoxia surveys at bi-weekly intervals to better define the areal extent and duration of hypoxia.

## Methods

Dissolved oxygen, temperature, pH , and salinity data are collected in situ using an electronic instrument called a Conductivity Temperature Depth recorder (CTD) that takes measurements from the surface to the bottom of the water column. The CTD, a Sea-Bird model SBE-19 SeaCat Profiler equipped with auxiliary dissolved oxygen, photosynthetically-active radiation (PAR) and pH sensors, is attached to a Rosette Sampler and lowered through the water column at a rate of approximately 0.2 meters per second and measurements are recorded every 0.5 seconds. In situ data are reviewed in real-time.

Water samples are collected using Niskin water sampling bottles that are attached to the Rosette Sampler. The Rosette is lowered off the stern of the Dempsey and the bottles are triggered remotely to take a water sample at any depth. Parameters for which surface and bottom waters are tested include dissolved silica, particulate silica, particulate carbon, dissolved organic carbon, dissolved nitrogen, particulate nitrogen, ammonia, nitrate + nitrite, particulate phosphorus, total dissolved phosphorus, orthophosphate, chlorophyll $a$, and total suspended solids.

Samples are filtered aboard the mini laboratory and preserved for later analyses at the Center for Environmental Science and Engineering at the University of Connecticut. From October to May, in situ and nutrient samples are collected once a month from 17 sites. Biweekly hypoxia surveys start in mid-June and end in September with up to 48 stations being sampled during each survey for in situ parameters.

Since 2002, CT DEEP has collected zooplankton samples from six stations and phytoplankton from ten stations across Long Island Sound. The samples are sent to researchers at the University of Connecticut who identify species composition, abundance, community structure, and spatial and temporal distribution throughout the Sound.

## LISICOS

The Long Island Sound Integrated Coastal Observing System (LISICOS) was established in 2003 as a component of a regional/national ocean observing system. The system was conceptualized as part of a water quality monitoring program that combined the traditional ship-based point sampling surveys with continuous, real-time sampling stations. Funding for the program was first provided through the Environmental Protection Agency EMPACT grant program and is now provided by the National Oceanic and Atmospheric Administration.

The initial goal was to develop "a capability to observe and understand the LIS ecosystem and predict its response to natural and anthropogenic changes".

LISICOS monitors water quality parameters (e.g., salinity, temperature, dissolved oxygen, surface waves, photosynthetically available radiation, chlorophyll) and meteorological parameters (e.g., wind speed, direction, barometric pressure, wave height) at up to eight stations across the Sound. Sensors are attached to a moored buoy at various depths (surface, mid, bottom). Data are transmitted every 15 minutes in real-time via satellite (telemetered) where they are stored in a database and uploaded to the internet. The system is maintained by the University of Connecticut.

This report presents a summary of the 2013 in situ data collected by CT DEEP. Data from LISICOS are presented with permission for informational purposes.

The CT DEEP LIS Water Quality Monitoring Program is synoptic in nature and is intended to characterize water quality conditions at one moment in time over a broad area (the entire Sound). Water column profile data provided by the program are useful for future determinations of volume of hypoxic waters. CT DEEP's program supports a long term monitoring database designed to detect changes in hypoxia due to changing conditions (i.e. management actions, climate change, productivity). The program also provides nutrient and biological data not available from fixed station buoy applications.

The LISICOS water quality sensors are attached to fixed locations and provide a holistic view of the conditions over a long span of time (i.e., continuous data from one station). The LISICOS continuously recording buoys have shown instances where vertical mixing within the water column raises the DO concentrations above the hypoxic thresholds for extended periods of time (e.g., days). These episodic conditions are not captured by CT DEEP surveys which occur bi-monthly during the hypoxic season.

As such CT DEEP's data provides a snapshot of hypoxic condition at one time while the LISICOS data provide a continuous measurement of hypoxia at specific buoy locations. Together these monitoring programs are better able to characterize the extent and duration of hypoxia across LIS. Both types of data contribute to a better understanding of hypoxia in LIS.

## What is Hypoxia?

The term "hypoxia" means low dissolved oxygen ("DO") concentrations in the water. Marine organisms need oxygen to live, and low concentrations, depending on the duration and the size of the area affected, can have serious consequences for a marine ecosystem. As defined by the Long Island Sound Study, hypoxia exists when DO drops below a concentration of 3 milligrams per liter ( $\mathrm{mg} / \mathrm{L}$ ), although ongoing national research suggests that there may be adverse affects to organisms even above this level, depending upon the length of exposure. In 2011,
 Connecticut adopted revised water quality criteria for dissolved oxygen. These criteria, designed to protect the state's waters from degradation, define hypoxia as DO concentrations below $3.0 \mathrm{mg} / \mathrm{L}$. Low oxygen levels can occur naturally in estuaries during the summer, when calm weather conditions prevent the mixing of the water column that replenishes bottom water oxygen during the rest of the year. However, studies of the limited historical data base for the Sound suggest that summer oxygen depletion in Western Long Island Sound has grown worse since the 1950s.

THE FREQUENCY OF HYPOXIA IN LONG ISLAND SOUND BOTTOM WATERS

## How Seriously Does Low Oxygen Impact the Sound?

Each summer low oxygen levels render hundreds of square miles of bottom water unhealthy for aquatic life. DO levels follow seasonal patterns with a decrease in bottom water DO over the course of the summer. Hypoxic conditions during the summer are mainly confined to the Narrows and Western Basin of Long Island Sound. Those areas comprise the section of the Sound west of a line from Stratford, CT to Port Jefferson, NY. The maximum extent of the hypoxic condition typically occurs in early August.

CT DEEP conducted eight cruises during the summer of 2013 between 3 June and 9 September. Over the course of the season, ten (10) different stations were documented as hypoxic and of the 259 site visits completed in 2013, hypoxic conditions were found 16 times. Compared to the 22-year averages, 2013 was below average in area and slightly above average in duration. In fact, 2013 had the third smallest area behind 1997 and 1992 (see page 7).

| Cruise | Start Date | End Date | Number of stations <br> sampled | Number of hypoxic <br> stations |
| :---: | :---: | :---: | :---: | :---: |
| WQJUN13 | $6 / 3 / 2013$ | $6 / 5 / 2013$ | 17 | 0 |
| HYJUN13 | $6 / 21 / 2013$ | $6 / 21 / 2013$ | 23 | 0 |
| WQUUL13 | $7 / 1 / 2013$ | $7 / 3 / 2013$ | 37 | 0 |
| HYJUL13 | $7 / 15 / 2013$ | $7 / 17 / 2013$ | 38 | 2 |
| WQAUG13 | $7 / 29 / 2013$ | $7 / 31 / 2013$ | 40 | 1 |
| HYAUG13 | $8 / 12 / 2013$ | $8 / 14 / 2013$ | 38 | 10 |
| WQSEP13 | $8 / 27 / 2013$ | $8 / 29 / 2013$ | 42 | 3 |
| HYSEP13 | $9 / 9 / 2013$ | $9 / 9 / 2013$ | 24 | 0 |

The peak event occurred during the HYAUG13 cruise between 12 and 14 August. The lowest dissolved oxygen concentration ( $1.34 \mathrm{mg} / \mathrm{L}$ ) was documented during the HYAUG13 cruise at Station A4. The hypoxia area maps for 2013 appear on pages 10-14.

## Based on CT DEEP and NEIWPCC-IEC data

Estimated Start Date
Estimated End Date
Duration (days)
Maximum Area (mi ${ }^{2}$ )

7/8/2013
9/7/2013
62
80.7

The Long Island Sound Study has defined hypoxia as dissolved oxygen concentrations below $3.0 \mathrm{mg} / \mathrm{L}$. On 25 February 2011, CT DEEP adopted revised water quality standards that specified dissolved oxygen in Class SA and SB waters (applicable to LIS) shall not be less than $3.0 \mathrm{mg} / \mathrm{L}$ at anytime.
Start date and end date are estimated by plotting CT DEEP and NEIWPCC-IEC data from stations A4 and B3 in Excel using a line with markers chart and then interpolating when the DO concentration drops below/rises above $3.0 \mathrm{mg} / \mathrm{L}$. Due to issues with the sampling vessel, NEIWPCC-IEC was unable to sample on 9/5/13. For the purposes of estimating the end date, the minimum value from the LISICOS Execution Rocks Buoy for that date was used.

## Timing and Duration of Hypoxia, 1991-2013

The figure and table below display the onset, duration, and end of the hypoxia events from 1991 through 2013 based on the $3.0 \mathrm{mg} / \mathrm{L}$ standard.

| LISS 3.0 mg/L |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| Year | Estimated Start <br> Date | Estimated End Date | Maximum Area <br> $\left(\mathrm{mi}^{2}\right)$ | Duration <br> $($ days $)$ |
| 1991 | July 19 | Aug 28 | 122 | 41 |
| 1992 | July 7 | Aug 30 | 80 | 55 |
| 1993 | July 9 | Sept 10 | 202 | 64 |
| 1994 | July 1 | Sept 6 | 393 | 68 |
| 1995 | July 12 | Aug 15 | 305 | 35 |
| 1996 | Aug 10 | Sept 12 | 220 | 34 |
| 1997 | July 27 | Sept 12 | 30 | 48 |
| 1998 | July 5 | Sept 15 | 168 | 73 |
| 1999 | July 2 | Aug 21 | 121 | 51 |
| 2000 | July 2 | Aug 6 | 173 | 35 |
| 2001 | July 10 | Sept 14 | 133 | 66 |
| 2002 | June 25 | Aug 28 | 130 | 65 |
| 2003 | July 5 | Sept 3 | 345 | 61 |
| 2004 | July 20 | Sept 12 | 202 | 55 |
| 2005 | July 14 | Sept 20 | 177 | 69 |
| 2006 | July 6 | Aug 27 | 199 | 53 |
| 2007 | July 16 | Sept 11 | 162 | 58 |
| 2008 | July 3 | Sept 19 | 180.1 | 79 |
| 2009 | July 19 | Sept 1 | 169.1 | 45 |
| 2010 | July 5 | August 13 | 101.1 | 40 |
| 2011 | July 6 | August 28 | 130.3 | 54 |
| 2012 | July 10 | Sept 10 | 288.5 | 63 |
| 2013 | July 8 | Sept 7 | 80.7 | 62 |
| Average | July 11 | Sept 3 | 179 | 55 |
| Deviation | $\pm 10$ days | $\pm 12$ days | $\pm 87 \mathrm{mi}^{2}$ | $\pm 13$ days |

Based on the LISS standard of 3.0 $\mathrm{mg} / \mathrm{L}$, the average date of onset was July 11 ( $\pm 10$ days), the average end date was September 3 ( $\pm 12$ days), and the average duration was 55 days ( $\pm 13$ days). The earliest onset of hypoxia (red text) occurred on 25 June 2002 and the latest end date (green text) occurred on 20 September 2005. The maximum area of hypoxia was 393 square miles (blue text) and occurred in 1994. The longest hypoxic event occurred in 2008 (magenta text) and lasted 79 days.

Timing and Duration of Hypoxia based on $3.0 \mathrm{mg} / \mathrm{L}$

# Yearly Comparison of Maximum Areal Extent and Duration of Hypoxia 

This graph utilizes the data presented on the previous page to illustrate the year-to-year differences in the maximum areal extent of hypoxic conditions. Based on the $3.0 \mathrm{mg} / \mathrm{L}$ DO standard the average areal extent was $178.8 \mathrm{mi}^{2}$ and the average duration was 55 days.

## Area and Duration of Hypoxia (DO<3.0 mg/L)

## Duration Based on Buoy Data Obtained From the LISICOS Network on 9 October 2013

The figures below are from the LISICOS website and depict the 2013 real-time bottom dissolved oxygen data (blue line); the average of the 9 or 12 year dataset, depending on the station (black line); and the variability observed over the historical station record (gray shading).

There were several periods of increased oxygen in the bottom waters that were not captured by CT DEEP surveys and the LISICOS buoys better reflect these reoxygenation events (blue peaks above the red hypoxia threshold line). The Execution Rocks Buoy showed DO concentrations dipped below $3.0 \mathrm{mg} / \mathrm{L}$ again on 13 and 14 September (just barely at 2.88 and $2.96 \mathrm{mg} / \mathrm{L}$ ) and for only a short duration. This results in an end date that is later than CT DEEP's estimated end date.

Data obtained from the LISICOS Execution Rocks and Western Sound Buoy Bottom Dissolved Oxygen Prediction Tool webpages (http:///lisicos.uconn.edu/do_fcst.php?site=exrx and http://lisicos.uconn.edu/do_fcst.php?site=wlis). Duration is calculated by LISICOS by summing the time (in days) of the number of samples where DO was below the specified value (T. Fake, pers comm. 18 October 2012). Data are provisional and subject to change.

The new ARTG Buoy also exhibited hypoxic conditions with a start date estimated as 7/24/13 and an end date estimated as 9/8/13. The minimum DO was $1.32 \mathrm{mg} / \mathrm{L}$ on $8 / 18$.

## Hypoxia Maps

The following maps depict the development of hypoxia based on CT DEEP cruise data through the 2013 season.

During the HYJUN13 survey all stations had DO concentrations above $4.8 \mathrm{mg} / \mathrm{L}$.

During the WQJUL13 survey DO concentrations were less than $4.8 \mathrm{mg} / \mathrm{L}$ at four stations. Data for all surveys are available upon request.

During the HYJUL13 survey, DO concentrations dropped below $4.8 \mathrm{mg} / \mathrm{L}$ at 18 stations and of those, one station was below $3.5 \mathrm{mg} / \mathrm{L}$ and two stations were below $3.0 \mathrm{mg} / \mathrm{L}$.

During the WQAUG13 survey, DO concentrations at Station A4 dropped below $3.0 \mathrm{mg} / \mathrm{L}$, while Stations B3 and 02 improved slightly, but were still less than $3.5 \mathrm{mg} / \mathrm{L}$. An additional 25 stations exhibited DO concentrations below $4.8 \mathrm{mg} / \mathrm{L}$.

Concentrations continued to decline during the HYAUG13 survey with three stations exhibiting DO concentrations below $2.0 \mathrm{mg} / \mathrm{L}$ and six stations below 3.0 $\mathrm{mg} / \mathrm{L}$. Additionally, eight stations had concentrations below $3.5 \mathrm{mg} / \mathrm{L}$ and ten stations were below $4.8 \mathrm{mg} / \mathrm{L}$. Conditions in 2013 were better than in 2012 when the DO concentration at Station A4 was below $1 \mathrm{mg} / \mathrm{L}$ and 23 stations were below $3.0 \mathrm{mg} / \mathrm{L} .2013$ had the third lowest areal extent over the course of the 22 -year sampling program, with only 1991 and 1997 having lower areal extents.

## Maximum Areal Extent (80.7 mi ${ }^{2}$ ) of Hypoxia

The map illustrates the dissolved oxygen concentrations in the bottom waters of Long Island Sound during the height of the hypoxic event.

The WQSEP13 survey found conditions improving, with no stations exhibiting DO concentrations below $2.0 \mathrm{mg} / \mathrm{L}$. Three stations still had concentrations less than $3.0 \mathrm{mg} / \mathrm{L}$ and five stations had concentrations less than $3.5 \mathrm{mg} / \mathrm{L}$.

Conditions continued to improve through the HYSEP13 survey with only one station exhibiting DO concentrations below $3.5 \mathrm{mg} / \mathrm{L}$ (B3). Eight additional stations continued to show DO concentrations below $4.8 \mathrm{mg} / \mathrm{L}$.

## Area of Dissolved Oxygen Below the Chronic Criterion for Growth and Protection of Aquatic Life for LIS

Aquatic organisms are harmed based on a combination of minimum oxygen concentration and duration of the low DO excursion. A DO concentration of $4.8 \mathrm{mg} / \mathrm{L}$ meets the chronic criterion for growth and protection of aquatic life regardless of the duration.

This chart illustrates the maximum area of bottom waters within Long Island Sound with DO concentrations less than $4.8 \mathrm{mg} / \mathrm{L}$. In 2013, the maximum area occurred during the WQSEP13 survey and was estimated at 466 square miles and was the lowest over the 22-year sampling program. From 1991-2013, the area affected by concentrations less than $4.8 \mathrm{mg} / \mathrm{L}$ averages 603.2 square miles and varies slightly from 466 to 730 square miles.

## Severe Hypoxia

The Long Island Sound Study provides information on LIS Hypoxia for inclusion in EPA's Report on the Environment (http://www.epa.gov/ncea/roe/) which reports on "the best available indicators of information on national conditions and trends in air, water, land, human health, and ecological systems...". The ROE Report uses $2.0 \mathrm{mg} / \mathrm{L}$ as a benchmark to liken conditions in the Gulf of Mexico to LIS. In this report, the term severe hypoxia is used to describe $\mathrm{DO}<2.0 \mathrm{mg} / \mathrm{L}$ and is discussed below.

This chart illustrates the maximum area of bottom waters of Long Island Sound with concentrations less than 2 $\mathrm{mg} / \mathrm{L}$. In 2013, the maximum area of LIS affected by severe hypoxia was $33.2 \mathrm{mi}^{2}$, a decrease from 2012. The average area, calculated from 1991-2013, is $58.1 \mathrm{mi}^{2}$. Based on CT DEEP data there were 15 days when DO was less than $2.0 \mathrm{mg} / \mathrm{L}$. Based on the LISICOS Execution Rocks data there were 4.73 days below $2.0 \mathrm{mg} / \mathrm{L}$.

For comparisons, the average size of the hypoxic zone in the northern Gulf of Mexico from 1985-2010 is roughly $5330 \mathrm{mi}^{2}$ (larger than the State of CT). The maximum area of the Gulf of Mexico hypoxic zone occurred in 2002 and was estimated at $8,841 \mathrm{mi}^{2}\left(22,898 \mathrm{~km}^{2}\right)$. The 2013 hypoxic zone covered $5837.9 \mathrm{mi}^{2}$ $\left(15,120 \mathrm{~km}^{2}\right)$ and was one of the largest areas on record exceeding the long -term average (http://www.gulfhypoxia.net/Research/Shelfwide\ Cruises/2013/PressRelease2013.pdf).

In LIS, 1994 and 2003 appear to be especially bad years for concentrations less than $2 \mathrm{mg} / \mathrm{L} .1994$ had cold winter bottom water temperatures and an unusually warm June which led to the establishment of strong stratification. The highest average Delta T in July 1994 was $8.54^{\circ} \mathrm{C} .2003$ was the second hottest summer since 1895 and the 28th wettest which also led to the Sound being very strongly stratified. Strong stratification (Delta T greater than 4) lasted for four months in 1994 (May-August) and only one month (July) in 2003.

According to the Northeast Regional Climate Center, (www.nrcc.cornell.edu/page_summaries.html) August 2013 was cooler than normal, although the three prior months were above normal across the Northeast. Additionally, precipitation was above normal for the summer period (June-August) with both Connecticut and New York receiving about 5 inches more than their averages.

## Anoxia D.O. $<1 \mathrm{mg} / \mathrm{L}$

For management purposes the Long Island Sound Study defines anoxia as DO concentrations less than $1 \mathrm{mg} / \mathrm{L}$. In ten of the twenty-two years there was no anoxia reported by CT DEEP. The greatest area with D.O. below $1 \mathrm{mg} / \mathrm{L}$ observed in LIS, based on ~biweekly sampling by CT DEEP, was during the summer of 2003. Prior to 2002, the average area of bottom waters affected by anoxia was $5.92 \mathrm{mi}^{2}$. From 2002-2012 the average area affected was $22.24 \mathrm{mi}^{2}$. The overall average area affected from 1991-2013 is $13.5 \mathrm{mi}^{2}$. A consistent decline was observed from 2003-2007. During the summer of 2008 three stations (A4, B3, and 02) were observed to have gone anoxic. In 2009, 2010, and 2011 CT DEEP did not document any stations with DO $<1 \mathrm{mg} / \mathrm{L}$. However, in 2009 and 2010 the Interstate Environmental Commission documented two stations that were anoxic. In 2011, no stations were documented to have gone anoxic by either the IEC or CT DEEP. However, the lowest concentration reported at the LISICOS Execution Rocks buoy (Station A4) for 2011 was $0.61 \mathrm{mg} / \mathrm{L}$. In 2012, CT DEEP documented two stations that were anoxic (A4 and B3). IEC documented two anoxic stations (A3 (further west than A4, Hewlett Point and H-C in Hempstead Harbor). LISICOS also documented anoxic conditions ( 4.04 days and minimum DO of $0.52 \mathrm{mg} / \mathrm{L}$ ). In 2013, anoxic conditions were not documented by DEEP, IEC or LISICOS.

## HABITAT IMPAIRMENT ASSOCIATED WITH HYPOXIA

Simpson et al, (1995) identified low oxygen tolerance thresholds for 16 individual species of finfish and lobster, and six aggregate species indices. For the most sensitive species (scup, striped sea robin) dissolved oxygen becomes limiting at less than $4.0 \mathrm{mg} / \mathrm{L}$, whereas more highly tolerant species (Atlantic herring and butterfish) did not decline in abundance until oxygen levels were below $2.0 \mathrm{mg} / \mathrm{L}$. Both demersal species biomass and demersal species richness begin to decline when dissolved oxygen levels fall below about $3.5 \mathrm{mg} / \mathrm{L}$. No finfish or macroinvertebrates were observed when dissolved oxygen fell below $1.0 \mathrm{mg} / \mathrm{L}$.

An index of habitat impairment (Biomass Area-Day Depletion, BADD) was developed based on the percent reduction in demersal finfish biomass associated with each $1 \mathrm{mg} / \mathrm{L}$ interval below $3.0 \mathrm{mg} / \mathrm{L}$. Based on Simpson et al (1996), demersal finfish biomass is reduced $100 \%$ (total avoidance) in waters with DO<1.0 mg/L. From 1.0-1.9 mg/L biomass is reduced $82 \%$, while a $41 \%$ reduction occurs at 2.0-2.9 $\mathrm{mg} / \mathrm{L}$, and a $4 \%$ reduction occurs at $3.0-3.9 \mathrm{mg} / \mathrm{L}$ dissolved oxygen. These rates are applied to the area-days within each DO interval calculated during each survey and summed over the hypoxia season defined here as 8 July - 7 September ( 62 d ). The index is then expressed as a percentage of the available area-days (sample area 2,723 $\mathrm{km}^{2} \times 62 \mathrm{~d}$, or 168,826 area-days).

[^2]
## WATER TEMPERATURE AND HYPOXIA

In LIS, water temperature plays a major role in the ecology of the Sound especially in the timing and severity of the summer hypoxia event. CT DEEP's monitoring program records water temperatures and salinity year round, but data collected during the hypoxia monitoring cruises are used to help estimate the extent of favorable conditions for the onset, extent, and end of the hypoxic event. The conceptual diagram below, while developed for Chesapeake Bay, applies to Long Island Sound. In LIS, there are two key contributors to hypoxia: nutrient enrichment and stratification. (Stratification is discussed more on page 22.) Nutrients, especially nitrogen, flow into the Sound from numerous sources including point sources like wastewater treatment plants and nonpoint sources such as stormwater runoff. This enrichment leads to excessive growth of phytoplankton, particularly in the spring. Temperature can stimulate or impede phytoplankton growth. As the plankton die, they begin to decay and settle to the bottom. Bacterial decomposition breaks down the organic material from the algae, using up oxygen in the process.

## 2013 Water Temperature Data

2013 maximum, minimum, and average water temperature $\left({ }^{\circ} \mathrm{C}\right)$ data are summarized below. Data are integrated across Long Island Sound (i.e., all stations and all depths) and are displayed by cruise. Data were obtained using the CT DEEP Sea Bird Sea Cat Conductivity, Temperature, Depth (CTD) profiler.

| Cruise | 2013 <br> Max | $1991-2012$ <br> Max | 2013 <br> Min | $1991-2012$ <br> Min | Average | $1991-2012$ <br> Average |

| WQDEC |  | 12.712 |  | 4.655 |  | 9.205 |

The Sound is coldest during February and March and warmest during August and September. The yearly average surface and bottom temperature of the Sound show slight increases over the period 1991-2013.

## Delta T and Stratification

The temperature difference between the bottom waters and the surface waters is known as "Delta T". This Delta T, along with salinity differences, creates a density difference, or "density gradient" resulting in a separation or "stratification" of water layers that hinders the oxygenated surface waters from circulating downward and mixing with the oxygen starved bottom waters. The pycnocline, or zone where water density increases rapidly with depth due to the changes in temperatures and salinity, inhibits oxygenated surface waters from mixing with oxygen deplete bottom waters exacerbating the hypoxia. The pycnocline typically develops in LIS in late spring/early summer when rapid surface water warming exceeds the rate of warming in the bottom waters and persists into early fall when it is disrupted by strong winds associated with storms which lead to mixing or cooling air temperatures. With the dissolution of the pycnocline, hypoxic conditions are alleviated/eliminated. The smallest Delta Ts occur during the winter when the water column is well mixed. The largest Delta T's occur during the early summer. The greater the delta T the greater is the potential for hypoxia to be
 more severe
The temperature graphs on page 21 show computer interpolations along the west-east axis of LIS generated from profile data collected during two CT DEEP surveys. During the HYJUL13 survey, surface water temperatures had warmed to an average of $23^{\circ} \mathrm{C}$ while the bottom water remained cooler around an average of $19^{\circ} \mathrm{C}$. This set up the largest differences in temperatures between the surface and bottom waters. The second graph shows how the water column was thermally stratified during the HYAUG13 survey when hypoxic conditions were at their worst. The graphs on page 22 show how the Delta T's varied over the course of the summer sampling season. Delta T's increased from the WQAPR13 survey through the WQAUG13 survey, setting up the stratification and leading to the maximum extent of hypoxia in late August. By the September survey Delta T's decreased to around $1{ }^{\circ} \mathrm{C}$ over much of the Sound. Delta T's continued to decrease during the HYSEP13 survey to around $0.1^{\circ} \mathrm{C}$, allowing the oxygenated surface waters to mix through to the bottom, leading to the end of the hypoxic event. The graphs also show how the Delta T varies spatially. The western Sound has higher Delta T's due to the limited flushing capacity, topology, and geology. In the east where cooler, oxygen rich, off- shore ocean water mixes with the Sound water, Delta T's are much lower and hypoxia rarely occurs.

## 2013 Delta-T Maps

| >0.5-1 | >3-3.5 | >5.5-6 | >8-8.5 |
| >1-1.5 | .3.5-4 | >6-6.5 | >8.5-9 |
| >1.5-2 | >4-4.5 | >6.5-7 |  |
| . 2 -2.5 | >4.5-5 | >7-7.5 | >9 |

Delta-T ${ }^{\circ} \mathrm{C}$

This table summarizes the minimum winter temperatures (January, February, and March), the maximum summer temperatures (June, July, August, and September), the maximum Delta T, and maximum hypoxic area at Station D3. Station D3 is located in the eastern-most and deepest portion of the Narrows (see map on page 1). The CT DEP 1991-1998 Data Review report (Kaputa and Olsen, 2000) found a positive correlation between the maximum Delta $T$ observed at D3 and the maximum area of hypoxia in the same year. Delta T was not correlated to the duration of hypoxia. 2012 had the warmest minimum winter temperature, 2004 had the lowest water temperature recorded, 2006 had the highest, 2011 had the highest $\Delta$ Tmax, and 1994 had the largest area of hypoxia.

| Year | Minimum Winter Temp ( ${ }^{\circ} \mathrm{C}$ ) | Maximum Summer Temp ( ${ }^{\circ} \mathrm{C}$ ) | Maximum $\Delta \mathrm{T}\left({ }^{\circ} \mathrm{C}\right)$ | Maximum Area of Hypoxia $\begin{gathered} \left(\mathrm{mi}^{2}\right) \\ \mathrm{DO}<3.0 \mathrm{mg} / \mathrm{L} \end{gathered}$ |

Kaputa, Nicholas P., and Christine B. Olsen. 2000. Long Island Sound summer hypoxia monitoring survey 1991-1998 data review. CTDEP Bureau of Water Management, Planning and Standards Division, 79 Elm Street, Hartford, CT 06106-5127, 45 p.

Date
Time series of $\Delta \mathrm{T}$ (surface water temperature - bottom water temperature) at station D3, 1991 through 2013.

Prior to 2004, when Station D3 became hypoxic the observed maximum delta-T was greater than $5^{\circ} \mathrm{C}$. Since 2004, this trend/pattern does not seem to hold. Over the period of record, 2011 had the highest observed Delta T at Station D3 ( $>8^{\circ} \mathrm{C}$ ) but the lowest dissolved oxygen concentration recorded in 2011 at D3 was $3.22 \mathrm{mg} / \mathrm{L}$. In 2012, the Delta T was again over $5^{\circ} \mathrm{C}$ and D 3 was in fact hypoxic (lowest dissolved oxygen was 2.84 $\mathrm{mg} / \mathrm{L}$ ). In 2013, D3 was not hypoxic despite the Delta T again being over $5^{\circ} \mathrm{C}$ (lowest concentration was $3.13 \mathrm{mg} / \mathrm{L}$ ).

## Salinity

Salinity is a measure of the dissolved salts content of seawater. It is usually expressed in practical salinity units (PSU). Salinity levels across Long Island Sound vary from 23 PSU in the Western Sound at Station A4 to 33 PSU in the eastern Sound at Station M3. The Thames, Connecticut, and Housatonic rivers are the major sources of freshwater entering the Sound. Summary statistics for salinity data collected from seven stations across the Sound from 19912012 are presented in the tables below. Data collected this year are also presented separately.

Boxplot of Surface (2m) Salinity Data from LIS

This box plot, based upon data collected during CT DEEP surveys from January - July 2013 ( $\mathrm{n}=377$, includes BOLD09 survey), shows the median surface salinity, range, interquartile range, and outliers by station. Surface in this case refers to data collected two (2) meters below the air/water interface. Salinity increases from west to east across the Sound.

This box plot, based upon data collected during CT DEEP surveys from January- July 2013 ( $\mathrm{n}=377$, includes BOLD09 survey), shows the median bottom salinity, range, interquartile range, and outliers by station. Bottom in this case refers to data collected five (5) meters above the sediment/water interface. The bottom waters are generally saltier than the surface waters.

Time Series Plot of the Avgerage Salinity Data from LIS
January - July 2013

This time series plot illustrates the temporal variability of the mean salinity values by station from January- July 2013 (WQAUG13 survey).

## Water Clarity

Water clarity is measured by lowering a Secchi disk into LIS by a measured line until it disappears. It is then raised until it reappears. The depth where the disk vanishes and reappears is the Secchi disk depth. The depth to disappearance is related to the transparency of the water. Transparency may be reduced by both absorption and scattering of light. Water absorbs light, but absorption is greatly increased by the presence of organic acids that stain the water a brown "tea" color and by particles. Scattering is largely due to turbidity, which can be attributable to both inorganic silt or clay particles, or due to organic particles such as detritus or planktonic algae suspended in the water. CT DEEP began taking Secchi Disk measurements in June 2000. Since then, 2740 measurements have been entered into our database; of those 1,621 are from the 17 stations sampled annually. The 2000-2013 average Secchi depth is 2.3 m with a minimum depth of 0.4 m (WQSEP05, station A4) and a maximum depth of 6.2 m (WQNOV00 Station K2). Below is a graph depicting Secchi disk depths from six of the axial stations sampled by CT DEEP LISS Water Quality Monitoring Program between May and September 2013.

## 2012 data

- Average Secchi Disk Depth: 2.36 m ( $\mathrm{n}=268$ )
- Minimum Secchi Disk Depth: $\mathbf{1 . 0} \mathbf{~ m}$ on multiple dates/stations
- Maximum Secchi Disk Depth: 4.0 m at Station F3 during the WQJUL12 cruise

## 2013 data

- Average Secchi Disk Depth: 2.33 m ( $\mathrm{n}=260$ )
- Minimum Secchi Disk Depth: 0.9 m at Station A4 during the WQAUG13 cruise
- Maximum Secchi Disk Depth: 4.2 m at Stations J2 during the WQAPR13 cruise 27

## pH and Ocean Acidification

Human activities have resulted in increases in atmospheric carbon dioxide $\left(\mathrm{CO}_{2}\right)$. The ocean absorbs $\mathrm{CO}_{2}$, greatly reducing greenhouse gas levels in the atmosphere and minimizing the impact on climate. When $\mathrm{CO}_{2}$ dissolves in seawater carbonic acid is formed. This acid formation reduces the pH of seawater and reduces the availability of carbonate ions. Carbonate ions are utilized by marine organisms in shell and skeletal formation. According to the NOAA Pacific Marine Environmental Laboratory Ocean Acidification Home Page, the pH of the ocean surface waters has already decreased from an average of 8.21 SU to 8.10 SU since the beginning of the industrial revolution and the Intergovernmental Panel on Climate Change predicts a decrease of an additional 0.3 SU by 2100 . (See http://www.pmel.noaa.gov/co2/OA/background.html.)

With this issue in mind, CT DEEP upgraded its SeaCat Profilers and began collecting and reporting pH data in August 2010. Data collected through the WQSEP13 survey are summarized below.

|  | n | Maximum | Minimum | Mean | Median | SE Mean | StDev | Variance |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Near Btm | 722 | 8.315 | 7.003 | 7.6807 | 7.6915 | 0.00935 | 0.2513 | 0.0632 |
| Bottom | 727 | 8.762 | 6.061 | 7.8195 | 7.815 | 0.0119 | 0.3218 | 0.1036 |
| Surface | 1116 | 8.806 | 6.066 | 7.9059 | 7.932 | 0.00869 | 0.2905 | 0.0844 |

## Chlorophyll a

Chlorophyll is a pigment found in plants that gives them their green color. It allows plants to absorb light from the sun and convert it to chemical energy during photosynthesis. In photosynthesis carbon dioxide and water are combined to produce sugar giving off oxygen as a byproduct. Microscopic plants, called phytoplankton, form the basis of the food web in Long Island Sound. However, as in most cases in nature, too much phytoplankton may not be a good thing. Water temperature, nutrient concentrations, and light availability all factor into the amount of phytoplankton biomass found in the Sound.

The concentration of chlorophyll $a$ is used as a measure to estimate the quantity of phytoplankton biomass suspended in the surface waters. It is most commonly used because it is easy to measure and because photosynthetic production is directly proportional to the amount of chlorophyll present.

Chlorophyll a concentrations are measured in situ using the CTD fluorometer as well as through the collection of grab samples using Niskin bottles. The grab samples are brought back into the onboard lab, filtered, and then sent to UConn for analysis.

The spring phytoplankton bloom occurs in Long Island Sound between February and April. Historically high levels of chlorophyll a in the western Sound during this time have been linked to summertime hypoxia conditions. Grab sample data from stations B3, D3, and F3 during the spring months are averaged together and then plotted to show the spring bloom conditions in the western Sound.

This time series plot illustrates the temporal variability of the surface chlorophyll a values (grab samples) by station from JanuaryApril 2013. The spring bloom was captured during the special CHFEB13 (2/14/13) survey and extended into the WQMAR13 (3/5/13) survey.

## JOB 6: PUBLIC OUTREACH

## GOAL

To increase awareness among anglers and the general public of the information products provided by this project and how this information contributes to state and federal efforts to enhance, restore and protect marine habitat and recreational fish populations.

## OBJECTIVES

1) Increase public awareness that research \& monitoring are essential to good fisheries management and the majority of marine fisheries research \& monitoring activities in Connecticut are funded through excise tax on fishing tackle and motorboat fuels

## SUMMARY

1. A total of 17,463 outdoor and environmental writers, marine anglers and boaters, marina operators, fishing tackle retailers, Fisheries Advisory Council (FAC) members, students, and members of the general public attended outreach events. The importance of research and monitoring to good fisheries management was incorporated into the programs (Table 6.2).
2. These same audiences also learned that good water quality and proper pollution prevention (non-fishing impacts) are essential to good fisheries habitat management.
3. Total attendance at two engagements with sportsmen clubs and other recreational environmental clubs was 65 (Table 6.2). The audience was encouraged to become actively involved in the fishery management process by attending public hearings and FAC meetings. Notices of public hearings were sent to hundreds of tackle shops and various media outlets including the DEEP website (www.ct.gov/deep/fishing).
4. Total attendance at two career day events with Connecticut high schools was 164 (Table 6.2). The students were encouraged to become actively involved in fisheries biology and management.
5. The message that the majority of marine finfish research and monitoring are funded through Federal excise taxes on fishing and motorboat fuels was emphasized at major department outreach events (Table 6.2).

## INTRODUCTION

Public outreach was formally incorporated into this project in 1997 (segment 17). An outreach plan was developed by project staff working closely with US Fish and Wildlife Service personnel. Six target audiences were identified in priority order (Table 6.1) in the outreach plan. This report summarizes F54R outreach activities conducted from March 2013 to February 2014 (segment 31).

Table 6.1:
Priority Audiences for Outreach Activities

1. Outdoor/environmental writers
2. Marine anglers
3. Marine boaters and Marina operators
4. Fishing tackle retailers
5. Fisheries Advisory Council (to CT DEEP)
6. General public

## RESULTS AND DISCUSSION

## Outdoor and Environmental Writers

DEEP press releases, project summaries, FAC quarterly reports and full annual reports were mailed and e-mailed out to several outdoor writers, members of the CT Outdoor Recreation Coalition (CORC) and Fisheries Advisory Council (FAC). Project staff were also interviewed concerning F54R activities in person, at public and regulatory hearings, and over the telephone by writers and reporters for the news media.

## Marine Anglers and Marine Boaters

Project personnel organized and assisted in DEEP, Marine and Inland Fisheries Division displays at two statewide fishing/hunting and boating shows. The shows were sponsored by CMTA, Dodge Trucks, Channel 3, Channel 30 and Connecticut Outdoor Recreation Coalition and were held in January and February of 2014 at the Connecticut Convention Center. These shows attracted 16,750 anglers, non-anglers, boaters, tackle retailers, legislators and general outdoor recreation enthusiasts. The theme for these show were "Enhanced Fishing Opportunities", Trophy Fish Close to Home" and "Marine Fisheries Division Angler Surveys". F54R activities were highlighted at these shows in displays entitled "Trophy Fish Award Program" and "Marine Angler Surveys, (a marine fisheries cooperative management program)". Audiences learned the importance of research and monitoring which are funded through excise taxes on fishing tackle and motorboat fuels. Colorful posters and pictures, brief project specific text and taxidermy reproductions helped draw attention to marine species monitored under F54R programs and solicit questions and discussion of those programs.

Several outreach displays were developed by project staff and mounted in the lobby and hallways at the Marine Fisheries Headquarters in Ferry Point State Park. These displays highlighted unique characteristics of Long Island Sound, public access, species identification, the trophy fish award program, marine angler surveys and gave a brief description of current F54R programs designed to protect the Sound's resources. These fisheries displays can easily be viewed by anglers, boaters and their families at this popular fishing and picnic area.

The Connecticut Department of Environmental Protection (DEEP) hosted the 'Fifth Annual Trophy Fish Award Ceremony' at the Northeast Fishing and Hunting Expo in the Connecticut Convention Center in Hartford on Saturday February 16, 2013. Seventy-five (43 marine anglers) were recognized for their fishing achievements during 2013. Four new state record holders, including the two new species awards, were honored. The Connecticut Department of Energy \& Environmental Protection (DEEP) hosted the ceremony. Seventy anglers were presented framed certificates recognizing their achievement of having caught or landed the largest fish in one of several species categories during 2013. Another five anglers were recognized as angler of the year. For a summary see: 2013 Marine Fisheries Trophy Fish Award Program Summary

## Fishing Tackle Retailers

Fishing tackle retailers provide an important avenue for communication between the department and anglers. A complete list of fishing tackle retailers is maintained and updated yearly on the CTDEEP website. Timely DEEP press releases, species fact sheets, Connecticut angler guides and Marine Fisheries Brochure are mailed to tackle retailers to keep them informed. Correspondence between the marine fisheries office staff and retailers are ongoing.

## Fisheries Advisory Council

The Fisheries Advisory Council, which represents a cross section of Connecticut residents with interests in fisheries issues, met quarterly to discuss statewide fisheries issues. After each meeting most Council members report Council discussions back to the fishing and environmental groups they represent. Council members also discussed monitoring and funding issues at meetings with state legislators. Many Council members visited Marine Fisheries displays at the Northeast Fishing and Hunting Expo, CMTA Boating Show, Trophy Fish Award Program and other activities the Fisheries Division held during 2013-14. 'A Study of Marine Recreational Fisheries in Connecticut' was emailed to Fishery Advisory Council members to keep them informed.

## General Public

Marine Headquarters is open daily Mon-Fri. attracting thousands to the public outreach displays at the office. Display topics included all F54R projects. Activities funded under other Federal Aid in Sport Fish Restoration projects were also highlighted; including Connecticut Pumpout Stations and Waste Reception Facilities (V-4), Motorboat Access Renovation and Development (F60D), Motorboat Access Area Operation and Maintenance (F70D), and Habitat Conservation and Enhancement (F61T).

Sport Fish Restoration projects were also highlighted at public schools and universities throughout the year. Presentations titled "Marine Fisheries Management / Sportfish Restoration and Marine Resource Management" were provided to students. These outreach events highlighted the importance of coastal resources and all facets of marine resource protection. Approximately 339 students attended Marine Fisheries Division presentations.

Finally, project staff led numerous workshops and speaking engagements throughout the state, as well as informational tours and talks at the Marine Fisheries Office (Table 6.2). These talks and tours reached all target audiences, especially the business community, teachers and students. Audiences learned how to become active participants in the fisheries management process, through public informational hearings and FAC Meetings.

## JOB 7: MARINE FISHERIES GIS

## GOAL

To maintain a geographic information system (GIS) of Project data to support map applications and geospatial analyses, assist with planning and executing Connecticut DEEP Marine Fisheries Division (MFD) surveys that support sport fish restoration goals, help people visualize the spatial extent of MFD project sampling efforts, assist in evaluating the effects of fishing and environmental conditions on the distribution and abundance of living resources in Long Island Sound, evaluate effects of marine spatial planning projects on living marine resources and fisheries in Long Island Sound, and improve coordination with other agencies.

## OBJECTIVES

1) Provide GIS-compatible, or GIS-ready, datasets and geo-referenced layers of data collected through other Jobs of this Project that are sanctioned by the Marine Fisheries Division.
2) Provide maps and geospatial analyses of Marine Fisheries Division data or other information relevant to managing living marine resources in Long Island Sound.

## INTRODUCTION

In recent years, there has been an increased need for staff to use geospatial technology to map and analyze marine environmental or fisheries related information. Project staff have also experienced an increasing number of requests to provide geospatial data to others (intra-agency, inter-agency, NGOs, academic institutions, etc) for use in, for example, fisheries stock assessments, habitat assessments, environmental sensitivity maps, and public outreach efforts. Therefore, in 2012, a new job (Job 7) was created within the project to support this need for geospatial datasets, data layers, analyses and products. This report includes results from the second year of Job 7.

## METHODS

GIS work was accomplished using ESRI ArcMap software and extensions licensed by the Connecticut DEEP. Published layers comply with Department policy pertaining to GIS data. Custom scripts were developed using well established scripting utilities (e.g. Python, HTML, CSS, Javascript). Products designed for the Internet adhere to Agency requirements for Agency websites, pages and products. A number of the custom applications, scripts and tools created during this segment can also be used as templates in the future.

## RESULTS

In an effort to encourage more saltwater fishing activity in the state, the CT DEEP Marine Fisheries Division has created an interactive map for the Internet, the "Saltwater Fishing Resource Map," (highlighted on the report cover and shown below) that allows anglers to find saltwater fishing resources in Connecticut and around Long Island Sound.

As shown in a close-up of the map's table of contents (at right), the information provided in the map include where a license can be obtained (sporting licensing agents), bait and tackle shop locations, party and charter boat locations, enhanced opportunity shore fishing sites, and CT boat launches with Long Island Sound Access. Users can select a point on the map directly, search for
 resources in a vicinity around a location, or search for resources by name. Anglers can get directions and more information for each resource, such as the name, phone number, and website.

The "Saltwater Fishing Resources Map" was custom designed in-house to provide an attractive, easy to use, web-based interface the public could use to find various types of information that might be relevant to saltwater fishing. For example, one of the data layers (enhanced opportunity shore fishing sites), shows the location of over forty sites along the CT coast with special regulations designed to improve the shore angling experience, mainly by increasing the likelihood of catching a legal sized summer flounder (fluke) or scup. That program is explained on our agency website: http://www.ct.gov/deep/cwp/view.asp?a=2696\&q=514534\&deepNav_GID=1647.

An example of the screen display for one of these enhanced shore fishing sites in an urban area (Seaside Park in Bridgeport, CT) is shown below: Note the right hand column of the screen displays information for this site from the CT Coastal Access Guide, another Agency website (http://www.lisrc.uconn.edu/coastalaccess/index.asp), and provides an indication of what type of amenities are available.

A number of links at the bottom of the web page also direct viewers to other web pages with information related to saltwater angling and contact information for the Marine Fisheries Division.

A key feature of CT DEEP's 'Saltwater Fishing Resources Map" is the ability to find nearby resources from any one, or all, of the data layers. This example (at left) shows the "Search Nearby" query for resources near Seaside Park, Bridgeport, CT, from all the available data layers, since all the layers are checked.

The results of the query are shown below. Note that information about the query results for each active layer can be expanded or collapsed in the column at right to show more or less information. (Information shown in the display should not be viewed as an endorsement of these entities, rather just an example of what information is available in the map.) In the section of the map displayed, there are results available for licensing agents, bait \& tackle shops, enhanced opportunity shore fishing sites and party/charter boat locations near Seaside Park, but only the information section for the party/charter boats is expanded.

Job 7 Page 5

Users may also select from nine (9) different basemaps and get directions to features in the "Saltwater Fishing Resource Map." The example below shows a relief basemap with a route highlighted from Hartford to New London. The right-hand panel shows the information for the enhanced shore fishing site selected (City Pier and Waterfront Park, New London) and step by step directions.

If the user hovers over an item in the Directions window, the map will zoom in and identify that section of the route (see below).

These features (and more!) make the "Saltwater Fishing Resources Map" a useful tool for saltwater anglers in CT and an impressive addition to the Agency website.

The DEEP receives many data requests regarding information collected during the Long Island Sound Trawl Survey (Job 2). Many of these data requests regard the distribution of different species or groupings of species during specific months and years. In order to make fulfilling these requests more efficient, the Marine Fisheries Division created custom tools for ArcMap using Python scripting that will produce the required maps. The tools can calculate the raw count or weight information directly from the Survey database, as well as the geometric mean by site or area. The tools have an easy to use graphical interface with plenty of "Help" information and allow for customization of the final map by selecting the symbology, modifying the template or incorporating additional GIS data layers. The tools will also catalog the data that they generate, allowing the Marine Fisheries Division to send data along with the maps. The tools will display messages as they run which show their progress. For long series of years, movie files can be created from the individual years to make it simpler to view changes over the time series. A selection of the custom tools, maps and dialog boxes are shown below.

The appearance of one of the custom tools project staff developed for use in ArcMap 10.0. This tool allows users to select which species, months, and years to calculate the statistics for display on the map. It also allows users to select biomass or count as the metric and to add additional GIS layers. Helpful information for the overall tool and individual parameters is displayed on the right to guide users in the use of the tool.

CT DEEP Long Island Sound Trawl Survey
Geometric Mean Biomass (kg) per Area Catch Distribution Map for Vertebrates All Months 2013 central and western LIS

## CT DEEP Marine Fisheries Division

Example map produced by one of the tools. This map shows the geometric mean biomass (kg) of vertebrates for all months of the Trawl Survey in 2013 for the areas of interest. The user selected the areas indicated by the red rectangles in the map extent. The tool defines the titles, labels, and symbology based on the user input.

Progress (status) dialog box that displays while one of the tools runs. It show the execution status, as well as, the name and location of files generated by the tool.

To further improve efficiency within the Department, additional tools were created to automate tasks that are performed on a regular basis. These tools perform tasks such as updating the data for the "Saltwater Fishing Resource Map," creating maps for reports, cataloging the SAS datasets for the Trawl Survey into a format compatible with ArcMap, and updating the datafiles in ArcMap when the SAS datasets are modified. Creating scripts to execute these tasks improves consistency and reduces the amount of time spent on repetitive tasks.

In cooperation with a NOAA data request, GIS layers providing the spatial extent and corresponding metadata files were created and disseminated electronically for sampling locations of Job 2.1 (LIS Trawl Survey), Job 2.2 (Estuarine Seine Survey) and Job 3 (Inshore Seine Survey). An image showing the data layers of the sampling locations in LIS (not including sites up rivers) in relation to historically productive recreational fishing areas in CT marine waters is shown below. This is some of the information to be included in the 2014 revision of the Environmental Sensitivity Index (ESI) Atlases for Long Island Sound. Previous ESI maps focused on fish and invertebrate resources from the Estuarine Living Marine Resources database. Since the updated ESI maps will incorporate relevant human use activities, in addition to biological resources, providing a layer to show the spatial extent of historically productive fishing areas was important. After further refinements, this layer will be made available to a number of public viewers for GIS data on the internet.
