## EXECUTIVE SUMMARY

Project: A Study of Marine Recreational Fisheries in Connecticut
Federal Aid Project: F54R-26 (Federal Aid in Sport Fish Restoration)
Annual Progress Report: March 1, 2006 - February 28, 2007
Total Project Expenditures (2006/07): \$652,831 (\$489,623 Federal, \$163,208 State)

## Purpose of the Project

The purpose of this project is to collect information needed for management of the marine recreational fishery. This information includes angler participation, effort, catch, and harvest; the relative abundance of finfish and specific population parameters for important selected species, water quality and habitat parameters, and assessment of fishery related issues such as hook and release mortality. The project also includes an outreach component to inform the public, and increase understanding and support for management programs and regulations.

The project is comprised of six jobs: 1) Marine Angler Survey, 2) Marine Finfish Survey, 3) Inshore Survey (Inactive), 4) Fishing Gear Studies (Inactive), 5) Cooperative Interagency Resource Monitoring, 6) Public Outreach. Job 3 has been inactive since March 1997. Job 4 has been inactive since 2000.

Information on marine angler activity is collected from intercept interviews conducted by DEP staff and through a telephone survey conducted by a National Marine Fisheries Service contractor as part of the coastwide Marine Recreational Fisheries Statistics Survey. The relative abundance of 40 species and more detailed population information on selected finfish are obtained from an annual Long Island Sound trawl survey. The relative abundance of young-of-year winter flounder and nearshore finfish species is obtained from fall seine sampling conducted at eight sites. Fishing gear and fishing practices are evaluated by conducting studies of hook and release mortality rates and through sampling catches of commercial fishing vessels taking species of recreational interest. Marine habitat is monitored and evaluated through cooperative interagency monthly sampling of water quality parameters (temperature, salinity, dissolved oxygen) at 20 to 25 fixed sites throughout the Sound. Public outreach is performed through speaking engagements at schools, with civic organizations and fishing clubs as well as through displays in the Marine Headquarters lobby and fishing shows. Project staff also keep the Fisheries Advisory Council informed on project activities and frequent media contacts provide broad newspaper coverage of project activities and findings.

## JOB 1: MARINE ANGLER SURVEY

## PART 1: MARINE RECREATIONAL FISHERY STATISTICS SURVEY

## OBJECTIVES (Summary)

- To estimate the number of marine anglers, fishing trips, fish caught, and number and weight of fish harvested.

## KEY FINDINGS:

- An estimated 380,155 anglers made 1.5 million trips in 2006. This is the fifth highest estimated number of anglers since the survey began in 1981. Total estimated trips made in 2006 were above the 1.4 million trip average (1981-2006).
- Marine anglers caught an estimated 6.2 million fish, harvesting 1.5 million in 2006.
- Five species: bluefish, scup, striped bass, summer flounder and tautog accounted for over 90 of both total catch and harvest estimates.
- Winter flounder harvest has declined to fewer than 25,000 fish annually since 2000 and the estimated harvest for 2006 was only 7,714 fish. The long-term average winter flounder harvest was 345,744 fish with peak harvests of over 1 million fish in the early to mid-1980's.

## CONCLUSIONS:

- Coastwide fishery management plans and strong recent year class production are resulting in increases in several fish populations and good catches of many of the primary recreational species.
- The once productive winter flounder resource no longer supports a substantial fishery in Connecticut. Landings (in number) that once ranked second or third behind bluefish and scup now account for less than $1 \%$ of fish harvested.

## RECOMMENDATIONS

Continue to obtain catch and harvest information and angler participation rates through the Marine Recreational Fisheries Statistics Survey in order to monitor the status of the recreational marine fishery.

## JOB 1: MARINE ANGLER SURVEY

PART 2: VOLUNTEER ANGLER SURVEY

## OBJECTIVES (Summary)

To characterize the size and catch composition of both kept and released fish observed by volunteer anglers.

## KEY FINDINGS:

- A total of 68 anglers participated in the survey and made 1,400 fishing trips in 2006. Volunteers including additional anglers involved in a fishing party made a total of 3,472 fishing trips. With multiple species taken per trip anglers reported 1,473 trips targeting bluefish, 2,304 trips for striped bass, 752 trips for summer flounder, 112 trips for winter flounder, 174 trips for scup and 324 trips for tautog.
- Volunteer anglers measured 2,253 individual bluefish measuring > 12 inches in length, 3,108 striped bass, 1,590 summer flounder, 108 winter flounder, 1,043 scup and 560 tautog. Over $60 \%$ of measured fish were released, providing valuable data not available through MRFSS except for the party/headboat at sea sampling survey.

## CONCLUSIONS:

- Volunteer anglers provide a tremendous amount of data on the size and catch composition of popular recreational species in Connecticut, supplying several stock assessments with scarce length information on released fish.

## RECOMMENDATIONS:

- Maintain the Volunteer Angler Survey as an effective means of characterizing angler behavior and particularly in collecting length data on released fish that are not available from the MRFSS survey.

## JOB 2 PART 1: LONG ISLAND SOUND TRAWL SURVEY (LISTS) OBJECTIVES (Summary)

- Provide an annual index of numbers and biomass per standard tow for 40 common species and age specific indices of abundance for scup, tautog, winter flounder, and summer flounder, and recruitment indices for bluefish (age 0 ) and weakfish (age 0 ).
- Provide length frequency distributions of bluefish, scup, striped bass, summer flounder, weakfish, winter flounder, tautog and other ecologically important species that can be converted to ages using modal analysis, age-length keys or other techniques.

## KEY FINDINGS:

- A total of 100,592 finfish, lobster and squid weighing 11,024 kg were collected in 2006.
- Forty-nine finfish species and thirty-eight invertebrate species (or taxa) were collected from 120 tows conducted in 2006. The total fish species count of 49 is the lowest observed in 23 years, the average (1984-2005) is 58 species per year. The Long Island Sound Trawl Survey has collected ninety-six finfish species since the survey began in 1984. No new finfish species were observed in 2006
- Atlantic sturgeon and long-finned squid were the only two species at record high abundances (geometric mean count per tow) in 2006. Hickory shad abundance remained near the record high level seen in 2005. Abundance of spiny dogfish was the highest since 1990.
- Adult scup abundance remains high relative to 1984-1998 levels but has dropped back down to the time series average level after a phenomenal peak in abundance in 2003. Similarly, summer flounder abundance has declined from the high levels recorded between 2001 and 2003 to more average levels as observed from 1996 to 2000.
- Adult bluefish abundance has dropped this past fall from the second highest levels in 2004, to those similar of the mid and late nineties. Young of year weakfish abundance dropped dramatically in 2006 after higher than normal catches from 1999 to 2005. Age 1+ weakfish abundance remains average. Striped bass abundance has been above average for the past 12 years.
- The spring survey index for tautog has remained low and below the time-series average for the past 14 years except for a short-lived increase in abundance recorded in 2002. The past eight years of winter flounder springtime abundance indices have been the lowest on record, with 2006 being a new record low for the time series.
- American lobster spring abundance dropped to a record low again in 2006. The spring index has been declining for seven years now (since 1999) and the past three years have been the lowest since 1988. Fall lobster abundance has also declined for seven years to a record low for the second year (similar to the spring index). Four of the past five years have been the lowest fall indices on record.
- Several other species were at or near record low abundance (by numbers) for both spring and fall surveys in 2006. Springtime indices of abundance have been at or near record lows for a couple years for black sea bass (2 years), cunner ( 3 years), fourspot flounder ( 2 years), red hake ( 4 years), and little skate ( 2 years). Windowpane flounder indices have been at or near record lows for the past seven years. Atlantic herring indices have been below average for the past nine years. Fall indices for butterfish have been hovered at or below average levels for the past seven years, while fall abundance has been below average for blueback herring for the past 9 years. Abundance of striped sea robin dropped significantly in 2006 to the second lowest value in the time series and the lowest since 1995.

## CONCLUSIONS:

- The abundance of recreationally important species in Long Island Sound remains moderate to high including scup, striped bass, and summer flounder. Recent high abundance of young-ofyear scup also bodes well for future catches for this species. The increased abundance of hickory shad in recent years provides an additional recreational fishing opportunity, especially to nearshore anglers. However, some recreational species like winter flounder and tautog have gone through a protracted period of declining abundance and this is cause for concern. Additionally, several species not typically targeted by recreational fishermen are at record low levels and may indicate shifts in species assemblages within Long Island Sound.

## RECOMMENDATIONS:

- Continue monitoring through LIS Trawl Survey to provide information for stock assessment purposes and to evaluate the effectiveness of management measures.

## JOB 2 PART 2: ESTUARINE SEINE SURVEY

## OBJECTIVES (summary)

- To provide an annual index of recruitment for young-of-year winter flounder and all finfish and crab species taken.

## KEY FINDINGS:

- The 2006 winter flounder young of the year index ( 0.9 fish/haul) was the lowest ranking out of 19 annual indices.
- The forage species abundance index was 59 in 2006, the sixth lowest of the time series, and well below the time series average of 93 forage fish/haul. (Atlantic silversides dominate this index).

## CONCLUSIONS:

- A significant decline of the winter flounder young of year index for 2006 following fairly low indices since 2000 and the absence of a strong year class since 1996 is not expected to change the bleak short term outlook for the stock.
- The inshore forage fish abundance index primarily reflects the abundance of Atlantic silversides, followed by striped killifish and mummichog, the dominant forage species taken in the survey.

## RECOMMENDATIONS:

- Continue to monitor young-of-year winter flounder and inshore forage species abundance through the September seine survey.

## JOB 3 A STUDY OF NEARSHORE HABITAT - INACTIVE THIS SEGMENT

## JOB 4 FISHING GEAR SELECTIVITY - INACTIVE THIS SEGMENT

## JOB 5: COOPERATIVE INTERAGENCY RESOURCE MONITORING OBJECTIVES

- Provide monthly monitoring of water quality parameters important in the development of summer hypoxia in Long Island Sound including temperature, salinity, and dissolved oxygen.
- Provide indicators of hypoxia impacts on living resources.

## KEY FINDINGS:

- Hypoxia first developed late in 2006 on or about July 4 and persisted for 57 days ending about August 29, 2006 - an earlier onset and twelve day shorter duration than in 2005.
- Severe hypoxia ( $<1.0 \mathrm{mg} / 1$ dissolved oxygen) affected $45 \mathrm{~km}^{2}$ during 2006. Such areas would be expected to be devoid of finfish, lobsters and crabs.
- Hypoxia ( $<=3.5 \mathrm{mg} / \mathrm{l}$ dissolved oxygen) extended over a maximum area of $896 \mathrm{~km}^{2}$ during early August, a larger area than during the 2004 and 2005 seasons but the shortest duration since 2000.
- The Biomass Area-Day Depletion Index (BADD) index for 2006 was about average at 7,017 or about $3.6 \%$ of the total area-days in the LIS sampling area.

## CONCLUSIONS:

- Although hypoxia developed early in the 2006 season following a late-July/early-August heat wave, a succession of storm events during the middle part of August provided sufficient turnover of the waters in the Sound to lead to a dissipation of hypoxia by the end of August. The end result was a year of average conditions for Long Island Sound.

## RECOMMENDATIONS:

- Continue conducting the water quality monitoring program to provide information needed to evaluate the effectiveness of measures to reduce nutrient loading to LIS and the impact of water quality improvements on marine life.

## JOB 6: PUBLIC OUTREACH OBJECTIVES

- Increase public awareness among anglers and the general public that information provided through this project contributes to state and federal efforts to enhance recreational fisheries conservation and that the majority of marine fisheries research and monitoring activities in Connecticut are funded through the Federal Aid in Sportfish Restoration Program.

## KEY FINDINGS:

- Outreach events directly reached 27,822 people through 19 events during this segment. The largest event was the "CMTA Boat Show" attended by 14,831 fishermen and hunters, followed by "Northeast Hunting and Fishing Show" at Mystic Seaport which had an attendance of 11,711.

## CONCLUSIONS:

- Large numbers of anglers and members of the general public are provided information about Marine Fisheries programs through participation in outdoor fishing \& hunting shows, Science and Career Days, public speaking engagements and displays at the Marine Fisheries Office.

## RECOMMENDATIONS:

- Continue outreach efforts.

EXPENDITURES

## JOB 1: MARINE ANGLER SURVEY

PART 1: MARINE RECREATIONAL FISHERY STATISTICS SURVEY
GOAL

To provide long term monitoring of marine recreational fishing activity including angler participation and catch statistics in a manner that is comparable to other Atlantic coastal states.

## OBJECTIVES

Provide estimates of:

1) Number of marine anglers in Connecticut each year.

A total of 380,155 marine anglers were estimated to have fished in Connecticut during 2006.
2) Total effort (trips) expended by anglers in Connecticut each year.

Marine anglers made 1,447,688 fishing trips in Connecticut during 2006.
3) Total catch (numbers of fish kept and released fish) and harvest (numbers and the weight of kept fish) of the most commonly sought species: bluefish, scup, winter flounder, summer flounder, tautog, and striped bass.

In 2006, marine anglers creeled 500,889 bluefish ( $2,483,854 \mathrm{lbs}$.), 521,303 scup ( $734,117 \mathrm{lbs}$.), 7,714 winter flounder ( $9,140 \mathrm{lbs}$ ), 106,779 summer flounder ( $339,548 \mathrm{lbs}$ ), 171,590 tautog ( $682,619 \mathrm{lbs}$.$) , and 77,665$ striped bass ( $1,309,306 \mathrm{lbs}$.).
4) Length-frequency of harvested bluefish, scup, winter flounder, summer flounder, tautog, and striped bass.

Length frequency distributions (minimum, mean, and maximum) were not available at press time.

## INTRODUCTION

The Connecticut Department of Environmental Protection (DEP), Bureau of Natural Resources, Marine Fisheries Division, has been collecting marine recreational fisheries information along the Connecticut coastline since 1979. However, in order to improve statewide marine fisheries statistics and become more consistent with other states, Connecticut joined with the MRFSS program in July, 1987. Before Connecticut's involvement in the MRFSS, data collection was conducted by NMFS's contractor just as in other states where state agencies do not participate in the program. This report includes state angler intercept survey work in 2006 and MRFSS angler effort and catch statistics from 1981-2006.

## METHODS

The MRFSS is based on two complementary surveys: A random telephone survey of households, and an intercept survey of anglers at fishing sites (NMFS 1992). MRFSS utilized a contractor to conduct the telephone survey to calculate total angler participation and trip estimates. Connecticut performed the angler intercept survey (angler interviews) in order to collect angler catch and effort data, biological data, and socioeconomic and demographic information.

The MRFSS's primary objectives are (1) to provide a collection of accurate and representative data on the marine recreational fishery and (2) to produce accurate and precise regional (e.g. ME-CT) catch estimates which can be used by fishery managers to assess the impacts of recreational fishing on finfish stocks. In order to produce estimates with adequate precision at the state level (where proportional Standard Error (PSE) $\leq 20 \%$, a modified version of Coefficient of Variation = S.E./Mean *100), the MRFSS initial intercept quota was tripled for Connecticut. Telephone and Intercept Surveys are collected in bimonthly time periods (termed Waves) and further broken down by mode in the Intercept Survey. In 2001, NMFS base allocations for the Northeast and Mid-Atlantic sub-regions were increased 1.5 times in order to increase effort and catch precision estimates for those areas. The increase was accomplished through a grant proposal submitted by the Atlantic Coastal Cooperative Statistics Program (ACCSP) Recreational Statistics Technical Committee and later approved by the ACCSP Coordinating Council. ACCSP is comprised of fifteen Atlantic coastal states and two federal agencies, which oversee and administer the collection of commercial and recreational fishery statistics. ACCSP provided funding for the additional intercept sampling as described in Table 1.1. However since state participation in 1987, Connecticut had already tripled NMFS Intercept Survey allocation and provided funding for those increases. ACCSP's involvement basically reduces Connecticut's expenditure toward processing of the additional intercepts. Wave 1 is not sampled in Connecticut or any states in the Mid Atlantic (NY-VA) and Northeast (ME-CT) subregions due to low fishing activity (NMFS 1992).

In addition, the sampling methodology of the party/charter boat mode was modified beginning in Wave 4 (July-August) 2003 in order to improve catch and trip estimates. The new changes in the survey (termed "the For-Hire Survey") called upon each state to provide and update a comprehensive list of current party/charter boat vessels and operators. This list provided a sampling frame where ten percent of for-hire vessel operators would be randomly selected to be contacted by telephone to report their fishing trip effort (angler trips) for a given two week period. Coupled with the telephone survey, pre-validation of vessels was performed where vessels were randomly selected and checked to determine if the vessel was out fishing or not. The same list would generate intercept assignments by wave. For-hire intercept assignments were split by vessel type (charter - 6 or less passengers) and party/head boats (more than 6) since sampling methods differ. Anglers fishing in the charter boat fishery were interviewed at dockside where party/charter boat anglers were interviewed on board while at sea. Dockside sampling of charter boat anglers was selected because of the six passenger limitation. At sea sampling was selected to increase the number of length and weight measurements on creeled fish in addition to length measurements on discarded fish. Intercept collection quotas for the
party/head boat mode were set by the number of trips (based on 2 samplers/trip). All other modes were allocated by the number of intercepts.

In 2006, a National Sport Fishing Expenditure Survey was added to the MRFSS Intercept Survey. The goal of the survey was to collect expenditure data from marine recreational anglers in order to estimate the economic importance of recreational fishing. Anglers interviewed in the Intercept Survey were also given the option of participating in a follow up mail survey. For further information regarding the expenditure survey please visit the following website: http://www.st.nmfs.gov/st1/econ.

## MRFSS Estimation Methods

MRFSS estimation methods used to compute catch and effort statistics were based on the following criteria: (1) improved guidelines for recording proxy data in lieu of missing data, (2) imputation for missing data, (3) telephone survey sample weighting, and (4) cleanup of historical intercept data (NMFS 1994). In cases where gaps or insufficient data occurs, proxy data (information obtained in the Telephone Survey from someone in a fishing household other than the angler) were used to fill voids in the database. In addition, catch and effort statistics for 1979-80 were omitted because of inadequate information (missing files that contained nonfishing household sample size information).

Angler participation and fishing trip estimates were derived primarily from the Telephone Survey and, in special situations, the Intercept Survey (NMFS 1992). In the Telephone Survey, households with telephones located in coastal counties or within 50 miles of the coastline were randomly selected and called to determine if a household fell into either of two categories: (1) households that comprised one or more marine recreational anglers and (2) non-fishing households. Households with anglers were further surveyed in order to collect fishing trip information used in estimating total fishing trips and angler participation. In situations where anglers did not possess a telephone (or live in a household), Intercept Survey data were used in order to account for that segment of the angling population that would otherwise be missed.

## MRFSS Catch Type Categories

Catch estimates were broken down into three categories: Catch Type A, B1 and B2. Catch Type A consisted of catches that were kept by anglers and available for inspection by field interviewers. Catch Type B1 included angler catches that were used for bait, discarded dead, etc., and were not available for inspection, and Catch Type B2 was comprised of fish that were caught and released alive. In this report, total catch estimates consist of Catch Types A+B1+B2. Creeled catch (fish removed from the population) include Catch Type A+B1 only. Catch Types A and B1 were the only catch groups estimated in both numbers and weights. Since Catch Type B1 are unobserved catches, Catch Type A mean weight estimates were used to expand Catch Type B1 estimates. Catch statistics in this document will be reported in numbers caught or as otherwise specified.

## RESULTS AND DISCUSSION

## Connecticut Intercept Survey 2006

During March-December 2006, a total of 1,378 interviews (intercepts) with marine anglers were conducted by Marine Fisheries Division staff for the MRFSS (Table 1.2). Overall intercept collection was lower than normal mainly due to the addition of the Expenditure Survey to the MRFSS and the time expended completing at sea headboat sampling. Intercept shortfalls occurred particularly in Waves 2 and 6 for NMFS + ACCSP quotas because of low fishing activity and poor weather conditions. Furthermore, most Connecticut-based party/charter businesses and marinas terminate their operations by November 1.

Table 1.2: Total Number of Angler Intercepts Collected and Party/Head Boat Trips Taken by Mode and Wave, 2006

## MRFSS 2006 Angler Participation and Fishing Trip Estimates and the MRFSS Time Series from 1981-2006

During 2006, an estimated 380, 155 marine anglers made 1,445,688 trips (Tables 1.3-1.4). The annual estimated number of marine anglers averaged 338,750 participants from 1981-06. The annual total of marine recreational fishing effort averaged $1,445,727$ trips for the same period. Connecticut residents comprised about $80 \%$ of the total marine fishing population whereas nonresident anglers made up the remaining 20\% from 1981-2006.

The three principal modes of marine recreational fishing include Shore Mode (anglers fishing from beach and bank or manmade structure), Private/Rental Mode (anglers fishing from a privately owned or rental boat), and Party/Charter Boat Mode where anglers pay a captain/vessel for hire to fish. The percentage breakdown of trips in 2006 by mode was $38.5 \%$ for shore mode, $3.1 \%$ party/charter boat mode and $58.4 \%$ for the private/rental mode. The percent distribution of fishing trips by mode for the time series was $36.3 \%$ for shore mode, $6.1 \%$ for party/charter mode and $57.7 \%$ in the private/rental mode.

## MRFSS Catch Estimates 2006

Total catch was estimated at 6,155,793 fish and creeled catch at 1,510,618 fish for 2006. Five popular species: bluefish, striped bass, scup, summer flounder, and tautog comprised over $90 \%$ of the estimated total catch and creeled catch (Tables 1.5-1.22). For that reason, these species will be the focus of discussion in this section. Precision estimates for bluefish, striped bass, summer flounder and tautog were near or below a PSE of $20 \%$ for both total and creeled catch. Scup PSE for total catch was below $20 \%$ however the harvested estimate was slightly elevated at $28 \%$. Total creeled catch in pounds for all species combined was estimated at 5.6 million lbs.

Catch estimates vary annually for most species primarily due to changes in abundance and fishing regulations. For more insight to historical accounts of Connecticut's marine recreational fishery regulations please refer to Table 1.23.

## BLUEFISH

Bluefish was the second most frequently caught species in Connecticut in 2006 with over $1,284,559$ million fish for total catch. The creeled catch estimate was 500,889 fish. Bluefish catch estimates in numbers comprised about $21 \%$ of the total catch and $33 \%$ of the total creeled catch for all species (Figure 1.3). Bluefish estimated creeled catch in pounds accounted for $44 \%$ of the total creeled catch. The proportion of bluefish released was $61 \%$.

The private rental boat mode comprised $52 \%$ and $50 \%$ for total catch and creeled catch estimates for 2006 . The shore mode accounted for $37 \%$ and $26 \%$ for total catch and creeled catch estimates. In the time series, however, the shore mode annual mean was approximately $44 \%$ and $46 \%$ for total and creeled catch estimates. Bluefish was the only species where the shore mode harvest was a substantial proportion of the overall catch when compared to other
species. This occurrence was most likely due to young-of-year bluefish (referred to as "snappers") entering into estuarine waters during the summer months becoming readily available to shore based anglers. This fishery is very popular with shore based anglers since "snappers" can be readily accessible and easily caught by anglers of all abilities. Depending on year-classstrength, total bluefish estimates may be driven by the shore based fishery.

In numbers caught, bluefish have been the most commonly caught and harvested species in the MRFSS time series ( $27 \%$ and $33 \%$, respectively). Bluefish total catch estimates range from a record low of 690,694 fish in 1988 to record high of about 6.3 million fish in 1982. The annual mean was about 1.8 million fish for total catch. Creeled catch estimates has ranged from 372,525 fish in 2000 to 3.3 million fish in 1981. The annual mean for creeled catch was 1.3 million fish. The annual mean rate anglers released fish alive was $26 \%$. The time series ranged for released bluefish was about $4 \%$ to a record high of $72 \%$ (2005 estimate).

## STRIPED BASS

Striped bass were the most frequently caught fish by marine recreational anglers in 2006 with an estimated total catch of about 1.7 million fish (comprising $28 \%$ of the total catch for all species). The private/rental boat mode accounted for $82 \%$ of the total catch. The creeled catch was estimated at 77,665 fish, a $28 \%$ reduction over the previous year. Striped bass creeled catch in numbers comprised $5 \%$ for all species. Creeled catch in weight was estimated at 1.3 million pounds and comprised $23 \%$ of the total creeled catch for all species. Approximately $96 \%$ of the total number of striped bass caught were released alive.

Throughout the MRFSS time series, striped bass total catch estimates varied from as low as 27,783 fish in 1981 to a record high of 1.8 million fish in 2005 (Figure 1.4). Low abundance of striped bass in the 1980's due to over-fishing followed by successful stock restoration efforts in the 1990's to present have resulted in a substantial upward trend of total catch. With the exception of 1981, 1983, and 1985 the creeled catch estimate has remained consistently low with an annual mean retention rate of about $7 \%$ (range $\simeq 0.7 \%-15 \%$ ). This is most likely attributed to catch restrictions implemented to curtail harvest in addition to recreational anglers increased awareness of conservation fishing practices (e.g. catch and release fishing).

## SUMMER FLOUNDER (Fluke)

The summer flounder recreational total catch estimate decreased slightly (4\%) from 2005 but was the second highest estimate ( $1,002,693$ fish) recorded in the time series. The estimated total catch comprised $16 \%$ of the total catch for all species (Figure 1.5). The private/rental boat mode accounted for $98 \%$ of the total catch. The 2006 creeled catch, however, dropped substantially from the previous year by $50 \%$. The creeled catch estimate in numbers ( 106,779 fish) accounted for about $7 \%$ of the total creeled catch for all species. The creeled catch in weight was an estimated $339,548 \mathrm{lbs}$. and accounted for $6 \%$ of the total creeled catch in weight for all species. Approximately $90 \%$ of summer flounder caught were released. This increase in release rate was most likely due to an increase in the minimum size from 17.5 to 18 inches in 2006.

In numbers caught, summer flounder comprised $7 \%$ and $5 \%$ of the total and creeled catch estimates in the MRFSS time series. The lowest estimated total catches occurred back to back in 1989 and 1990 with only 44,541 and 56,352 summer flounder, respectively. Creeled catch estimates have been highly variable (range $=17,707$ in $1990-576,160$ fish in 1983).

## WINTER FLOUNDER

Winter flounder total catch increased from an estimated 4,484 fish in 2005 to 31,452 fish in 2006. The total creeled catch estimate was 7,714 fish. Both total and creeled catch estimates comprised only $0.5 \%$ for all species (Figure 1.6). The private/rental mode comprised $67 \%$ of the estimated total catch. Since 1992, winter flounder annual estimates have fallen well below the time series mean of 421,503 fish for total catch and 345,722 for creeled catch. Winter flounder creeled catch in weight was estimated at 9,140 pounds, or about $0.2 \%$ of the total creeled catch in weight for all species. The proportion of winter flounder released increased from $16 \%$ in 2005 to $76 \%$ in 2006.

## SCUP (Porgy)

Scup was the third most frequently caught species (slightly behind bluefish) in Connecticut for 2006 with $1,249,419$ and 521,303 fish estimated for total and creeled catches. The private/rental boat mode accounted for $80 \%$ of the total catch. Scup estimates comprised $20 \%$ and $35 \%$ of the total and creeled catch estimates for all species (Figure 1.7). In weight, creeled catch was estimated at 734,117 pounds in 2006. The proportion of scup released was approximately $58 \%$.

## TAUTOG (Blackfish)

Tautog, locally referred to as blackfish by anglers, are one of the few year round resident species of Long Island Sound. Tautog total catch in 2006 was estimated at 311,174 fish and 171,590 fish for the creeled catch total (Figure 1.8). The creeled catch estimate in 2006 increased 2.3 times from the 2005 estimate. The total and creeled estimates comprised $5 \%$ and $11 \%$ of the total for all species. In weight, the creeled catch was estimated at 682,619 pounds. The proportion of tautog released was $45 \%$.

## LENGTH FREQUENCY DISTRIBUTION FOR BLUEFISH, STRIPED BASS, SCUP, SUMMER FLOUNDER, WINTER FLOUNDER, AND TAUTOG

Length measurements were collected as described in the MRFSS Procedures Manual. Attempts were made to measure all marine finfish when available or in random sub-samples when large catches were encountered. Length frequency distributions for Type A (observed fish) as well as catch and trip statistics can be queried on the following NMFS web site: http://www.st.nmfs.gov/st1/recreational/queries/index.html. However, length frequency data was not available at press time since the web site was currently under construction.

## MODIFICATIONS

None.

## JOB 1: MARINE ANGLER SURVEY

 PART 2: VOLUNTEER ANGLER SURVEY
## OBJECTIVES

Provide estimates of:

1) Size composition data on both kept and released bluefish, striped bass other common species.

Anglers participating in the Volunteer Angler Survey measured bluefish, striped bass and other species. Length frequencies of popular species: bluefish, striped bass, summer flounder, winter flounder, scup, tautog and weakfish are listed in Tables 1.1A-1.7A.
2) Catch frequency (trips catching 0,1,2,...fish) data on both kept and discarded fish.

Catch frequency data and percent distribution on both kept and released are listed in Tables $1.1 \mathrm{~A}-1.2 \mathrm{~A}$.

## INTRODUCTION

The purpose of the Volunteer Angler Survey (VAS) is to supplement the National Marine Fisheries Service, Marine Recreational Fishery Statistics Survey by providing additional length measurement data particularly concerning fish that are released. In 1994, the VAS program was incorporated into the Marine Angler Survey (Job 1) in order to improve and expand the survey.

The survey's initial objective was to collect marine recreational fishing information concerning finfish species with special emphasis on striped bass. In 1994, the collection of bluefish length measurements was added to the survey to fully understand that fishery. In 1997, length measurement information on other marine finfish was added to the survey. This report primarily consists of data collected in 2006.

## METHODS

The VAS is designed to collect trip and catch information from marine recreational (hook and line) anglers who volunteer to record their fishing activities by logbook. The logbook format consists of recording fishing effort, target species, fishing mode (boat vs. shore), area fished (subdivisions of Long Island Sound and adjacent waters), catch information concerning finfish kept (creeled) and released, and striped bass and bluefish length measurements (Appendix 1.1A). In 1997, the logbook was modified in order to collect length measurement data on other species as well. Instructions for volunteers were provided on the inside cover of the postage paid logbook. Each participating angler was assigned a personal numeric code for confidentiality purposes. After the logbook data were computer entered, logbooks were returned to each volunteer for their own personal record. For their participation, volunteers were sent a soft insulated lunch cooler in addition to updates of survey results. Furthermore, to improve communications with recreational anglers and to encourage more public input, volunteers were
notified of upcoming public hearings including proposed and final changes in recreational fishing regulations.

## RESULTS AND DISCUSSION

Over the years the number of participants in the survey ranged from as low as 18 anglers participating in 1979 to a high of 115 anglers in 1997. Advertising the VAS program through the DEP's annually published Connecticut Angler's Guide including the State web site (http://dep.state.ct.us/bunatr/fishing) has helped increase volunteer participation. The guide is distributed to anglers purchasing freshwater licenses in addition to being circulated by bait and tackle shops and other entities.

## VAS 2006

In 2006, a total of 68 anglers participated in the survey which was down from the previous year's 84 anglers. Those 68 anglers took 1,400 fishing trips. Volunteers including additional anglers involved in a fishing party made a total of 3,472 fishing trips (note: targeted trips in the following paragraphs are not additive to the trip total since more than one species may be sought during an angler trip). The percent of successful trips, where at least one fish of any species was caught, was relatively high at $93 \%$ for boat anglers and $78 \%$ for shore anglers. Besides striped bass and bluefish, VAS anglers pursued and caught a wide range of inshore and offshore pelagic species and recorded length measurements on many species. This report contains statistics on species anglers targeted the most and that are under a current fishery management plan (bluefish, striped bass, summer flounder, scup, winter flounder, tautog, black sea bass, and weakfish). Please refer to tables $1.1 \mathrm{~A}-1.2 \mathrm{~A}$ for length frequency distribution tables and catch trip frequency distributions for kept and discarded (released) fish are listed in figures $1.1 \mathrm{~A}-1.7 \mathrm{~A}$.

## Bluefish

VAS participants made 1,473 targeted bluefish trips (boat and shore modes combined) and recorded a total of 2,648 adult bluefish caught (bluefish $>12$ inches). Of the total number of targeted trips, only $8 \%$ were unsuccessful. The overall catch including trips not targeting bluefish was 3,472 fish. Of the overall catch, anglers measured 2,253 adult bluefish (65\%) and released about $69 \%$. The $50^{\text {th }}$ percentile length measurement for bluefish was approximately 25 inches (total length). The targeted catch-per-unit-of-effort (CPUE) was 1.8 and 0.61 fish per angler trip for total and creeled catches.

## Striped bass

Volunteers made 2,304 trips targeting striped bass and caught a total of 4,631 fish (overall catch including trips not targeting striped bass was 4,682 fish). About $10 \%$ or 236 trips targeting striped bass were unsuccessful. Of the overall catch, about $94 \%$ of the catch was released. VAS anglers measured 3,108 striped bass ( $66 \%$ of the overall catch). Legal size striped bass ( $\geq 28$ inches) comprised about $15 \%$ of the measured catch. The percent of legal size striped bass released was estimated at $63 \%$. The $50^{\text {th }}$ percentile length measurement for striped
bass was about 18.5 inches. Striped bass ranged in length from as small as 6 inches to 50 inches. Targeted CPUE was 2.0 and 0.12 fish per angler trip for total and creeled catches.

## Summer flounder

A total of 752 fishing trips were directed toward catching 2,491 summer flounder. Only $6 \%$ of the trips targeting summer flounder were unsuccessful. The overall catch was 2,559 fish. Volunteers measured 1,590 fish or about $62 \%$ of the overall catch. Approximately $80 \%$ of the overall catch was released. About $60 \%$ of the measured catch was comprised of fish less than the legal length limit of 18 inches. VAS anglers released $9 \%$ of summer flounder measuring 18 inches and greater. The $50^{\text {th }}$ percentile length measurement for summer flounder was about 16.5 inches. Length measurements ranged from 5 to 29 inches. Summer flounder targeted CPUE was 3.3 and 0.7 fish per angler trip for total and creeled catches.

## Winter flounder

Volunteers made 112 trips that targeted winter flounder. These targeted trips produced just 74 fish. The overall catch including non-targeted trips was 130 winter flounder. Of the total trips targeting winter flounder, $23 \%$ of the trips were unsuccessful. Of the overall catch, 108 winter flounder ( $83 \%$ ) were measured. Anglers released about $25 \%$ of the overall catch and about $5 \%$ of the measured catch were sub-legal in size ( $<12$ inches). Anglers released $7 \%$ of legal sized fish ( $\geq 12$ inches). The $50^{\text {th }}$ percentile length measurement for winter flounder was about 13 inches. Length measurements ranged from 10 to 19 inches. Winter flounder targeted CPUE was 1.5 and 0.9 fish per angler trip for total and creeled catches.

## Scup

Volunteers made 174 targeted trips for scup producing a total of 1,045 fish. Of the total trips targeting scup, only $6 \%$ of the trips were unsuccessful. The overall total catch was 1,513 fish. Volunteers measured about $69 \%$ ( 1,043 fish) of the overall total catch. Of the overall total catch, $68 \%$ were released. Sub-legal fish ( $<10.5$ inches) comprised $52 \%$ of the measured catch. The proportion of legal sized fish ( $\geq 10.5$ inches) released by anglers was approximately $29 \%$. The $50^{\text {th }}$ percentile length measurement for scup was about 10 inches. Length measurements ranged from as little a 3 inches to 16 inches. Scup targeted CPUE was 6.0 and 2.1 fish per angler trip for total and creeled catches.

## Tautog

VAS anglers made 324 trips that targeted tautog and caught a total of 730 fish. Of the total trips targeting tautog, $7 \%$ of the trips were unsuccessful. The overall total catch was 795 fish. Volunteers measured 560 tautog or about $70 \%$ of the overall total catch. About $30 \%$ of the measured catch was less than the legal size of 14 inches. Of the legal size measured catch, approximately $43 \%$ were released. The $50^{\text {th }}$ percentile length measurement for tautog was about 15.5 inches. Length measurements ranged from 6 to 26 inches. Tautog targeted CPUE was 2.3 and 0.8 fish per angler trip for total and creeled catches.

## Weakfish

There were only 15 targeted weakfish trips and a total of 10 fish were caught by VAS anglers. One fish was incidentally caught by non-targeted trips and none were released of the overall catch. Weakfish ranged in size from 14 to 35 inches in length. Due to inadequate length measurement data, length frequency distribution information was not presented in this report. Depressed catch rates by anglers indicates that weakfish remain in low abundance.

## Black sea bass

VAS angler took 28 trips targeting black sea bass catching 45 fish. However, the overall catch was 368 black sea bass. Of the overall total catch, $94 \%$ were released. Volunteers measured 264 fish or $72 \%$ of the overall total catch. Of the measured catch, $88 \%$ of the catch was below the 12 inch legal length limit. The $50^{\text {th }}$ percentile length measurement for black sea bass was about 7 inches and the percent of legal size fish released was $24 \%$. Black sea bass targeted CPUE was 1.6 and 0.14 fish per angler trip for total and creeled catches. The nontargeted catch rates suggests that the black sea bass fishery in Long Island Sound is an incidental fishery for most anglers.

## CONCLUSIONS

VAS anglers provide valuable recreational fisheries data at a relatively low cost. In addition, collecting length data on released fish is often difficult or unattainable through conventional intercept surveys. The VAS program provides this information which is essential in assessing the recreational fishery. VAS data is also used in monitoring and assessing the recreational striped bass fishery in Connecticut as required through the Atlantic States Marine Fisheries Commission. Furthermore, VAS data is now being used in bluefish, summer flounder, winter flounder and weakfish stock assessments and will most likely be involved in other species as well. Any anglers interested in participating in the program can contact Rod MacLeod at 860-434-6043, or e-mail address: rod.macleod@po.state.ct.us or writing to State of Connecticut, DEP, Marine Fisheries Office, P.O. Box 719, Old Lyme CT 06371.

## MODIFICATIONS

None.

## ACKNOWLEDGMENTS

I am very grateful to all anglers who have participated in the survey. Without their cooperation and assistance, the VAS program would not be possible.

## APPENDIX 1.1A: Connecticut Volunteer Angler Logbook

Volunteer Angler Survey Logbook Instructions: Listed below are instructions for filling out the logbook. Upon logbook completion, tape the prepaid postage logbook shut and drop it off in the mail. All information is kept confidential. Once the information is entered in our computer system and error checked, the logbooks will be returned for your own records. If you any questions or comments regarding the survey, please contact Rod MacLeod at (860) 434-6043 or at E-Mail address rod.macleod@po.state.ct.us.
(1) Please enter the month and day fishing trip took place.
(2) Fishing start time in military time (Example: $11 \mathrm{am}=1100,1 \mathrm{pm}=1300 \mathrm{hrs}, 2 \mathrm{pm}=1400$, etc.).
(3) Actual fishing time or lines wet to the nearest $1 / 2$ hour. Do not include travel time.
(4) Number of anglers in fishing party.
(5) Areas fished most in descending order as described on the chart located on the inside cover of logbook. Also, if most of the fishing took place in a river please place a check mark in the box provided.
(6) Check mark your mode of fishing (boat or shore).
(7) Enter species code for 1st (primary) targeted species and 2nd (secondary) targeted species provided in the species code list below.
(8) Number of anglers that caught fish.
(9) Place a check mark if no fish were caught for the entire fishing party.

Catch Information: Catch information should include the total number of fish caught by the entire party. Enter the number of fish kept and released in the designated boxes. If you caught fish other than those in the pre-coded boxes, please refer to the species code list below and enter the code in the designated blank boxes. If you caught a fish not listed in the species code list, please write down the common name(s) in the blank box(es) provided.

Length Measurement Information: Please try to provide length measurement data on popular species caught including kept and released fish (exclude skates, cunners, etc). Fish must be measured to the nearest $1 / 2$ inch from the tip of the snout to the end of the tail (total length). In case of large catches, try to measure your catch on a random basis. Measuring just large fish will not accurately reflect the actual size or age distribution of the population. When handling and measuring sublegal sized fish, anglers should use their best judgement and experience to insure that those fish are returned to the water unharmed.

## Species Code List:

| 01 Albacore | 12 Cusk-eel |
| :--- | :--- |
| 02 Alewife | 13 Dogfish (all species) |
| 03 Atlantic Salmon | 14 Dolphin (Mahi-Mahi) |
| 04 Blackfish (Tautog) | 15 American Eel |
| 05 Blowfish (Puffer) | 16 Summer Flounder (Fluke) |
| 06 Bluefish (Adults $>$ 12in.) | 17 Goosefish (Monkfish) |
| 07 Atlantic Bonito | 18 Haddock |
| 08 Brown Trout (Sea-Run) | 19 Atlantic Herring |
| 09 Butterfish | 20 Spanish Mackerel |
| 10 Atlantic Cod | 21 Hakes (Red, Spotted) |
| 11 Cunner | 22 Atlantic Mackerel |

23 White Marlin
24 Atlantic Menhaden
25 Pollock
26 Scup (Porgy)
27 Atlantic Sailfish
28 Windowpane Flounder
29 Black Sea Bass
30 Searobins (all species)
31 American Shad
32 Sharks(oceanic)
33 Skates

34 Smelt
35 Spot
36 Striped Bass
37 Swordfish
38 Oyster Toadfish
39 Atlantic Tomcod
40 Bluefin Tuna
41 Weakfish
42 Whiting (Silver Hake)
43 White Perch
44 Winter Flounder

45 Snapper Bluefish ( $\leq 12 \mathrm{in}$.)
46 Yellowfin Tuna
47 Bigeye Tuna
48 Blue Marlin
49 Blueback Herring
50 Hickory Shad
51 Little Tunny (False Albacore)
52 Skipjack Tuna
53 Atlantic Wolffish
54 Northern Kingfish
55 Atlantic Croaker

## JOB 2 PART 1: LONG ISLAND SOUND TRAWL SURVEY (LISTS)

## CRUISE RESULTS FROM THE 2006 SPRING \& FALL SURVEYS

## STUDY PERIOD AND AREA

The Connecticut Division of Marine Fisheries completed twenty-three years of bottom trawl surveys in 2006. The Long Island Sound Trawl Survey encompasses an area from New London, Connecticut to Greenwich, Connecticut and includes waters from 5 to 46 meters in depth in both Connecticut and New York state waters. Long Island Sound is surveyed in the spring during April through June and during the fall from September through October. This report includes results from the 2006 spring and fall sampling periods as well as providing time series information since the commencement of the survey in 1984.

## GOAL

To collect, manage, synthesize and interpret fishery independent data on the living resources of Long Island Sound for the fishery management and information needs of Connecticut biologists, fishery managers, lawmakers and the public.

## OBJECTIVES

1) Provide an annual index of counts and biomass per standard tow for 40 common species.
2) Provide age specific indices of abundance for scup, summer flounder, tautog and winter flounder.
3) Provide a recruitment index for bluefish (age 0) and weakfish (age 0).
4) Provide length frequency distributions of bluefish, scup, striped bass, summer flounder, tautog, weakfish, winter flounder, and other ecologically important species suitable for conversion to age using modal analysis, age-length keys or other techniques.
5) Provide annual total counts and biomass for all finfish species taken.
6) Provide annual total biomass for all invertebrate species taken.
7) Provide a species list for Long Island Sound based on LIS Trawl Survey sampling, noting the presence of additional species from other sampling conducted by the Marine Fisheries Division.

## INTRODUCTION

The Long Island Sound Trawl Survey (LISTS) was initiated in 1984 to provide fishery independent monitoring of important recreational species in Long Island Sound. A stratifiedrandom design based on bottom type and depth interval was chosen and forty sites were sampled monthly from April through November to establish seasonal patterns of abundance and distribution. Seven species were initially of primary interest: bluefish, scup, striped bass, summer flounder, tautog, weakfish, and winter flounder. Length data for these species were collected from every tow; scup, tautog, and winter flounder were sampled for ageing. All fish species were identified and counted.

Since 1984, several changes have been incorporated into LISTS. In 1991, the sampling schedule was changed to a spring/fall format, although sampling is still conducted on a monthly basis (April - June, September, and October). Beginning in 1992, species were weighed in aggregate with an onboard scale to provide indices of biomass. And finally, more species have been sampled for lengths, such as windowpane and fourspot flounders, and important forage species such as butterfish, long-finned squid, and several species of herrings. By 2003, a total of 20 finfish species and two invertebrate species (lobster and long-finned squid) had been added to the original list of seven species measured. Additionally, rarely occurring species (totaling less than 30 fish/year each) are now measured. All of these changes served to improve the quality and quantity of information made available to fishery managers for local and regional assessment of stock condition, and to provide a more complete annual inventory of LIS (Long Island Sound) fishery resources.

In the fall of 1999, an unusual die-off of lobsters occurred, particularly in the western portion of the Sound known as 'The Narrows' (Johnson and Shake 2000). This event lead to speculation that this area, which is adjacent to highly urbanized portions of Connecticut and New York, was experiencing a broad decline in living resources including finfish. Since the standard 40 sites per month did not cover this area, new sites were needed to evaluate finfish and invertebrate species composition and abundance west of a north-south line from Norwalk, CT to Eatons Neck, NY. Therefore, starting in 2000, additional sites in the western portion of the Sound were sampled during each month in addition to the LISTS sites. Sampling and data analysis for the Narrows, although not funded by this project or covered by the objectives, will be discussed in a separate section of this report (see 'Narrows') following the 'Modifications’ section.

## METHODS

## Sampling Design

LISTS is conducted from longitude $72^{\circ} 03^{\prime}$ (New London, Connecticut) to longitude $73^{\circ}$ 39' (Greenwich, Connecticut). The sampling area includes Connecticut and New York waters from 5 to 46 m in depth and over mud, sand and transitional (mud/sand) sediment types. Sampling is divided into spring (April-June) and fall (Sept-Oct) periods, with 40 sites sampled monthly for a total of 200 sites annually. The sampling gear employed is a 14 m otter trawl with a 51 mm codend (Table 2.1). To reduce the bias associated with day-night changes in catchability of some species, sampling is conducted during daylight hours (Sissenwine and Bowman 1978).

LISTS employs a stratified-random sampling design. The sampling area is divided into $1.85 \times 3.7 \mathrm{~km}$ ( $1 \times 2$ nautical miles) sites (Figure 2.1), with each site assigned to one of 12 strata defined by depth interval ( $0-9.0 \mathrm{~m}, 9.1-18.2 \mathrm{~m}, 18.3-27.3 \mathrm{~m}$ or, $27.4+\mathrm{m}$ ) and bottom type (mud, sand, or transitional as defined by Reid et al. 1979). For each monthly sampling cruise, sites are selected randomly from within each stratum. The number of sites sampled in each stratum was determined by dividing the total stratum area by $68 \mathrm{~km}^{2}$ ( 20 square nautical miles), with a minimum of two sites sampled per stratum (Table 2.2). Discrete stratum areas smaller than a sample site are not sampled.

## Sampling Procedures

Prior to towing at each site, temperature $\left({ }^{\circ} \mathrm{C}\right.$ ) and salinity ( ppt ) are measured at 1 m below the surface and 0.5 m above the bottom using a YSI model $30 \mathrm{~S}-\mathrm{C}-\mathrm{T}$ meter. Water is collected at depth with a five-liter niskin bottle, and temperature and salinity are measured within the bottle immediately upon collection.

The otter trawl is towed from the 15.2 m aluminum R/V John Dempsey for 30 minutes at approximately 3.5 knots, depending on the tide. At completion of the tow the catch is released onto a sorting table and sorted by species. Finfish, lobsters and squid are counted and weighed (to the nearest 0.1 kg ) in aggregate by species with a precision marine-grade scale ( $30 \mathrm{~kg},+/-10$ gm capacity). Catches weighing less than 0.1 kg are recorded as 0.1 kg . For the initial two years (1984 \& 1985), lobsters were the only invertebrates recorded. Squid abundance has been recorded since 1986. Since 1992, additional invertebrate species have been weighed in aggregate, and some have been counted. The complete time series of species counted and weighed in the survey is documented in Appendix 2.4.

For selected finfish species, lengths are recorded to the centimeter as either total length or fork length (e.g. measurements from 100 mm to 109 mm are recorded as 10 cm ) and entered in the database as 105 mm (Table 2.3). Lobsters are measured to 0.1 mm carapace length. Squid are measured to the centimeter mantle length and horseshoe crab measurements are taken using the prosomal width (cm).

The number of individuals measured from each tow varies by species, and also depends on the size of the catch and range of lengths (Table 2.3). If a species is subsampled, the length frequency of the catch is determined by multiplying the proportion of individuals in each centimeter interval by the total number of individuals caught. Some species are sorted and subsampled by length group so that all large individuals are measured and a subsample of small (often young-of-year) specimens are measured. All individuals not measured in a length group are counted. The length frequency of each group is estimated as described above, i.e. the proportion of individuals in each centimeter interval of the subsample is expanded to determine the total number of individuals caught in the length group. The estimated length frequencies of each group are then appended to complete the length frequency for that species. This procedure is often used with catches of bluefish, scup, and weakfish, which are usually dominated by young-of-year or discrete age/length classes.

Scup, summer flounder, tautog, weakfish and winter flounder are sampled for age
determination (Table 2.3). Subsamples of scup, stratified by length group, are measured to the nearest mm (fork length) and scales from each individual are taken for ageing. Scup scales are removed posterior to the pectoral fin and ventral to the lateral line. The scales are pressed onto plastic laminate with an Ann Arbor roller press to obtain an impression of the scale, which is then viewed with a microfiche reader at 21x. Scales are also taken from all summer flounder greater than 60 cm . At least 15 scales are removed from the caudal peduncal area. These scales are pressed and aged to supplement the National Marine Fisheries Service age key used to age summer flounder collected by LISTS (see below). Most tautog taken in LISTS are aged due to the low numbers caught in recent years (under 250 fish). Tautog are iced and taken to the lab, where their total length (mm), sex, and total weight (gm) are recorded and their age is determined from opercular bones (Cooper 1967). Subsamples of winter flounder, stratified by length group (Table 2.3), are iced and taken to the lab where they are measured to the millimeter (total length), weighed (gm), sexed, their maturity stage determined (NMFS 1989), and they are aged with whole and sectioned otoliths (Simpson et al. 1988). Weakfish scales are obtained and processed as described above for scup, and otoliths are sectioned and read using procedures described in Simpson et al. 1988.

In reports prior to 2001, three species were not included in annual and seasonal totals: American sand lance, bay anchovy, and striped anchovy. These species, with the possible exception of striped anchovy, can be very abundant in Long Island Sound, but are not retained well in the otter trawl. Additionally, many of these fish are young-of-year and often drop out of the net as it is retrieved and wound on the net reel. For this reason they were not included in the list of species to be counted when LISTS was started in 1984. However, to document the occurrence of these species in LISTS catches, American sand lance was added in 1994, striped anchovy was added in 1996, and bay anchovy was added in 1998. Since 2001, adults of these three species are added to the annual and seasonal totals and the young-of-year are listed if present in the year’s catch but are not quantified (Table 2.7, Appendix 2.4). Young-of-year for these three species are included in the database but are cataloged with a separate species identifier and quantities are considered estimates (Appendix 2.2).

## Data Analysis

## Indices of Abundance: Annual Mean Count and Weight per Tow

To evaluate the relative abundance of common species, an annual spring (April - June) and fall (September-October) geometric mean number per tow and weight per tow (biomass, kg) is calculated for the common finfish and invertebrate species. To calculate the geometric mean, the numbers and weight per tow are logged (loge) to normalize the highly skewed catch frequencies typical of trawl surveys:

$$
\text { Transformed variable = } \ln (\text { variable }+1) .
$$

Means are computed on the log scale and then retransformed to the geometric mean:

$$
\text { geometric mean }=\exp (\text { mean })-1 .
$$

The geometric mean count per tow was calculated from 1984-2006 for 38 finfish species, lobster, and long-finned squid (1986-2006). The geometric mean weight per tow was
calculated using weight data collected since 1992 for the same species, plus an additional 13 invertebrates.

For the seven finfish species that were measured on every tow--bluefish, scup, striped bass, summer flounder, tautog, weakfish, and winter flounder--biomass indices were calculated for the years 1984-1991 by using length/weight equations to convert length frequencies to weight per tow. Bluefish, scup, weakfish and winter flounder lengths were converted using equations from Wilk et al. 1978; striped bass conversions were accomplished using an equation from Young et al. 1994; and summer flounder and tautog conversions were accomplished using equations developed from LISTS data from 1984-1987 and 1984-1996 respectively.

## Indices of Abundance: Indices-at-Age and Age Group

Annual age specific indices (indices-at-age matrices) were calculated for scup, striped bass, summer flounder, winter flounder and tautog. The age data used to calculate the indices came from three sources: striped bass ages were derived using the von Bertalanffy (1938) equation; summer flounder age-length keys were obtained from the National Marine Fisheries Service (NMFS) Northeast Fisheries Science Center spring and fall trawl surveys combined with LISTS ages ( $>59 \mathrm{~cm}$ ); and scup, winter flounder and tautog age-length keys (in 1 cm intervals) were obtained directly from LISTS. Since fish growth can fluctuate annually as a function of population size or other environmental factors, a year and season specific age-length key was used wherever possible. Once lengths have been converted to age, the proportion at age is multiplied by the abundance index of the appropriate season to produce an index of abundance at age.

Recruitment (young-of-year) and age 1+ (all fish age one and older) indices were calculated for bluefish and weakfish. Observed modes in the length frequencies were used to separate the two groups.

The specific methods used to calculate indices-at-age for each species were as follows:

- Bluefish. Since bluefish are not aged, modes observed in the fall length frequencies were used to separate bluefish into age 0 and age 1+ groups, and a geometric mean catch per tow was calculated for each group. Comparison of the mean length-at-ages reported for young-of-year and age 1 bluefish in the New York Bight (Chiarella and Conover 1990) and Long Island Sound (Richards 1976) with LISTS length frequencies suggests that bluefish can easily be identified as either age 0 (snapper bluefish) or adults (age 1+). Richards (1976) and Chiarella and Conover (1990) determined that most bluefish less than 30 cm are age 0 . A discontinuity in the LISTS fall length frequencies occurs most years between 26 cm and 39 cm (Gottschall and Pacileo 2006, Table 2.29). Therefore 30 cm was determined to be a suitable length for partitioning age 0 and age one fish.

Although North Carolina state biologists have aged bluefish, their age keys were not used to age Long Island Sound bluefish because North Carolina mean lengths-at-age are not consistent with modes observed in Long Island Sound bluefish length frequencies. This difference suggests that growth may vary by region, or that early and late spawned bluefish may be differentially distributed along the coast (Kendall 1979).

- Scup. An index-at-age matrix was developed for 1984-2006 using spring (May-June only) and fall (September-October) LISTS data. April data was omitted since very few scup are taken at this time. A total of 8,136 scup aged between 1984 and 2006 were used to make year and season specific age-length keys ( 1 cm intervals). In the relatively few instances when the season/year specific key failed at a given 1 cm length interval, a three-year pooled key was used to determine the age. Three-year pooled keys were calculated using the years preceding and following the "run" year. For the terminal year, only two years were used for the pooled key. The final index-at-age was computed for both spring and fall indices-at-age. Since very few scup older than age 9 are taken, an age $10+$ group is calculated by summing indices for ages 10 and up. To represent the full adult portion of the population an age $2+$ index is calculated by summing the indices for ages 2 through $10+$.
- Striped bass. To approximate the ages of striped bass taken in the survey, the average of the Chesapeake Bay and Hudson River striped bass von Bertalanffy parameters ( $\mathrm{L}_{\max }=49.9 \mathrm{in}$, $\mathrm{K}=0.13, \mathrm{t}_{0}=0.16$, Vic Crecco, pers. comm.) were used in the rearranged von Bertalanffy equation:

$$
t=(1 / K) *\left(-\log _{e}\left(\left(L_{\max }-L_{t}\right) / L_{\max }\right)\right)+t_{0}
$$

Since this equation estimates age $t$ as a fraction of a year, the estimates were rounded to the nearest year (e.g. age 3 = ages 2.5 to 3.4). A spring catch-at-age matrix was developed for 1984 through 2006 by apportioning the spring index by the percentage of fish at each age.

- Summer flounder. The year and season specific age-length keys ( 1 cm intervals) used to age LISTS catches were provided by NMFS from their spring and fall trawl surveys. These keys were supplemented with fish caught and aged by LISTS ( 60 cm and over). Since 2001, whenever the season/year specific key failed at a given 1 cm length interval a pooled year key using only adjacent years was used (Gottschall and Pacileo 2002). Since it is thought that growth rates for summer flounder have changed over time, a pooled key using only adjacent years would more accurately represent fish that could not be aged by the season/year specific key. Using this methodology, the catch-at-age matrix will remain unchanged for all but the terminal year, which will be updated as the following years' data becomes available.
- Tautog. An index-at-age matrix was developed for 1984-2006 using all survey months. A total of 5,308 tautog were aged from 1984 to 2004, however only the 4,266 samples from April, May, June, September and October (standard LISTS months) were used to make year and season specific age-length keys ( 1 cm intervals). Tautog collected in 2005-2006 have been aged, however, a second reading is currently underway because of staff changes in readers, therefore, length frequencies was converted to an age frequency using a pooled age key for these two years. Since the length frequency of tautog collected in LISTS is sparse for fish greater than 60 cm in length and the age determinations are so varied, all fish 60 cm or greater were assigned a length of 60 cm . The final index-at-age was computed as the sum of the spring and fall indices-at-age. Finally, due to the paucity of tautog older than age 20 in LISTS catches, an age 20+ group is calculated by summing indices for ages 20 and up.
- Weakfish. Age 0 and age 1+ indices were calculated for both spring and fall surveys, 1984 2006. Since few weakfish are taken in April, the spring geometric mean was calculated
using only May and June. All weakfish taken in spring are assumed to be age 1+. Similar to bluefish, the fall age 0 and $1+$ index was calculated by using length frequencies to separate the catch. Since a break in the fall length frequencies generally occurs between 24 and 32 cm each year (Gottschall and Pacileo 2006, Table 2.42), weakfish less than 30 cm are considered to be age 0 while those greater than or equal to 30 cm are ages $1+$.
- Winter flounder. An index-at-age matrix was developed for 1984-2006 using April and May LISTS data. June data was not used since length frequency data suggest that many adult winter flounder have left the Sound by this time (an exception was made for 1984, the first year of LISTS, because very few samples were taken in the spring months). A total of 16,960 winter flounder aged between 1984 and 2006 were used to make year and region (east of Stratford Shoal, west of Stratford Shoal) specific age-length keys in 1 cm intervals. Similar to scup and summer flounder, three year pooled keys using only the adjacent years (two years for the terminal year runs) were used to assign ages if year specific keys were not available.

## RESULTS AND DISCUSSION

## Overview of LISTS 2006 Spring and Fall Surveys

The spring survey normally starts during the second week of April each year. The 2006 spring survey was delayed due to several interruptions in rebuilding the main engine on the R/V John Dempsey. The research vessel was hauled in early January and unforeseen problems were encountered after the engine was dismantled and issues with parts availability were encountered. The April cruise was canceled due to these delays, however the May cruise commenced at the normal time on the $10^{\text {th }}$ of the month. This cruise took 11 days to complete and finished on the $31^{\text {st }}$ of May. The June cruise commenced on the $13^{\text {th }}$ of June and finished on the $26^{\text {th }}$ after nine sampling days. Without the April cruise in 2006, only 80 LISTS tows and 6 Narrows tows were completed during the spring survey (Table 2.4, and 2.53). A map for the May and June survey showing the sites selected and sites sampled is provided in Figure 2.2 and 2.3. These figures provide a short description if a site had to be relocated and the reasons why. Two samples were relocated in both the May and June surveys. Additional site information is provided in Table 2.5 (May) and Table 2.6 (June) including date of sample, time, tow duration, latitude/longitude, and surface and bottom temperature and salinity. Spring Narrows sampling information is additionally provided at the bottom of each of the respective figures and tables.

The R/V John Dempsey encountered further mechanical problems during the fall of 2006, which interrupted the sampling schedule again. Twenty tows were completed between September $6^{\text {th }}$ and $11^{\text {th }}$. After completing the fourth tow of the day on September $11^{\text {th }}$ the hydraulic power take off broke down. Again, parts availability and rebuilding the PTO delayed sampling until October $2^{\text {nd }}$ when sampling was resumed. The remaining twenty tows were completed by the $12^{\text {th }}$, and finished up the 40 tows per cruise site selection that was started in September. Three Narrows tows were also completed on October $4^{\text {th }}$. The sites selected for October were never started because of a scheduled haul-out for sand blasting and painting of the hull and installation of a bow thruster. A map for the September-October sampling is provided in Figure 2.4 and sample information provided in Table 2.7.

This year we have provided a list of samples where duration of a tow was less than the
standard 30 minutes, including the reason why that particular tow was interrupted (Table 2.8). Six tows in May were less than the standard thirty minutes; five LISTS tows and one Narrows tow in June were also cut short in duration. There were six short tows in the fall and one of the three Narrows tows was also stopped short. Typical reasons for short tows less than the thirty minute standard is either lack of room at a particular location because of observed pots in a tow lane, or a drop in speed of the vessel because of gear interactions (lobster pots) or other debris in the net, or a complete stop because of a hang (a wreck or rock pile). Survey crew will often attempt to finish an interrupted tow by resetting beyond the obstruction or observed gear and completing the thirty minutes, however, oftentimes this isn't possible and sites will be moved to similar strata as close to the aborted tow as possible. Typically, a minimum of fifteen minute tow duration is required for the LISTS survey and a minimum of 10 minutes duration for the Narrows survey, with some exceptions. Two such exceptions occurred in 2006; one on May $19^{\text {th }}$ (SP2006028-12 minutes) and another during the last tow of the year, October $14^{\text {th }}$ (FA2006040 - 9 minutes).

## Cooperative Sample and Data Collection

Throughout the time series LISTS survey staff have been participating in cooperative efforts for sample collections, data requests, and special projects using survey personnel, equipment, and other resources. Most of these cooperative efforts are with state researchers or agencies, the National Marine Fisheries Service, Atlantic States Marine Fisheries Commission, New England and Mid-Atlantic Councils, and researchers or grad students associated with state or local universities. Table 2.9 illustrates many of the organizations that requested data in 2006 while Table 2.10 shows sample request received and fulfilled (each by month). In recent years many requests for samples have come from high schools, aquariums, or other educational organizations needing finfish and invertebrates for teaching purposes. Additionally, our own staff often have sample or data requests for media or other public outreach events (see job six of this report).

## Number of Species Identified

Forty-nine finfish species were observed in 2006 and no new species were caught (Table 2.11). From 1984 to 2006, ninety-six species were identified (Appendix 2.1), averaging 58 species per year with a range of 49 to 70 species (Fig 2.5). In addition, a total of thirty-eight types of invertebrates were collected in 2006 (Table 2.12). Most invertebrates are identified to species. However, in some difficult cases, invertebrates were identified to genus or higher taxon.

## Total Catch

Appendix 2.4 presents a time series (1984-2006) of the finfish species collected each year and their respective rank by numbers. Annual total biomass of invertebrates are also included in this appendix, and are ranked by weight (kg).

A total of 92,042 finfish weighing $10,500.2 \mathrm{~kg}$ were sampled in 2006 (Table 2.13). In seventeen out of the last twenty-three years butterfish has been the highest-ranking finfish (numbers) in LISTS. In 2006, butterfish ranked first in numbers but second in weight, with 50,022 individuals weighing $1,631.4 \mathrm{~kg}$. Scup (porgy) ranked second in number, with 28,829 individuals and first in weight for the year ( $4,636.1 \mathrm{~kg}$ ). Bluefish ranked third by number ( 2,100 fish), but sixth by weight. During the previous seven years weakfish had been the third most
dominant species by number with good catches of juveniles during fall sampling, however, in 2006 only 241 individuals (ranked $17^{\text {th }}$ ) were recorded. Winter flounder (1,699 fish) ranked fourth numerically and bay anchovy $(1,492)$ ranked fifth this year. Smooth dogfish ranked third in weight for the second year in a row with $1,176.6 \mathrm{~kg}$ followed by striped bass 418.7 kg . Together the top five species, accounted for $91.4 \%$ of total numbers of finfish and $65.8 \%$ of total weight. The top two species (by weight), butterfish and scup, accounted for about $59.7 \%$ of the total biomass.

Scup topped the spring catches with 18,293 fish and accounted for almost half of the total catch and more than half (53.6\%) of the spring biomass (Table 2.14). Scup catches this spring were the forth highest in the time series and the largest since the record catch of 50,651 scup in 2002. Three prominent length groups for scup were seen this past spring with modes peaking at $11-12 \mathrm{~cm}, 18 \mathrm{~cm}$, and $29-30 \mathrm{~cm}$ (Table 2.40). Butterfish were the second most abundant fish taken with 10,914 fish ( 579.1 kg ) being observed in the May and June samples. Winter flounder, most likely undersampled in 2006 because of the lack of April sampling, nonetheless was ranked third with 1,591 fish ( 262.3 kg ) being recorded. Winter flounder ranked first in number of fish taken during spring sampling for sixteen straight years until scup became more abundant in the catches in 2000. Flounder then fell to second rank each year until 2005 when it surpassed scup once again then dropped to the current third rank. The second highest biomass recorded in spring 2006 was from 256 smooth dogfish at 818.7 kg followed by butterfish.

The fall survey in 2006 differed from the previous five years in that few weakfish were seen in the catches. Weakfish typically rank second behind butterfish in recent years, but only 215 fish were seen in the fall survey in 2006 (Table 2.14). This dropped the weakfish rank to seventh. In twenty-one out of twenty-three years butterfish have ranked first. This past fall there were 39,108 butterfish ( $1,052.3 \mathrm{~kg}$ ) recorded and 10,536 scup ( 806.9 kg ). Scup ranked second in both number and biomass followed by bluefish in number with 2,062 fish ( 316.5 kg ). Smooth dogfish again ranked high in biomass (3rd) with 357.9 kg from 76 individuals. Bay anchovy, moonfish, and windowpane flounder were the forth, fifth and sixth most abundant species during the fall period with 534, 361, and 232 fish respectively. The top three species by count; butterfish, scup and bluefish, made up $95.4 \%$ of the total catch in numbers and $64.8 \%$ of the biomass for this survey.

A total of $1,002.6 \mathrm{~kg}$ of invertebrates were taken in 2006 (Table 2.13). Long-finned squid ( 326 kg ), horseshoe crab ( 205.8 kg ) and American Lobster (197.9 kg) were the top three species in biomass. These three species accounted for $72.7 \%$ of the biomass. Seven hundred and forty eight (748) lobsters were recorded in the forty fall tows along with 7,802 long-finned squid and 109 horseshoe crabs. Boring sponge ( 51.3 kg ) and spider crab ( 50.6 kg ) were the forth and fifth most dominant invertebrate species by weight.

The total catch of invertebrates taken in the spring was 534.4 kg (Table 2.15). Longfinned squid had record spring abundance ( 11.55 squid/tow, Table 2.16 ) in 2006 with 1,763 squid caught. Long-finned squid ranked first by weight during the spring and accounted for $35.0 \%$ of the spring biomass followed by American lobster ( $28.6 \%$ or 152.9 kg ). American lobster abundance was at a record low this past spring and only 562 were caught in the eighty tows conducted. Horseshoe crab ( $11.1 \%$ or 59.4 kg ) and spider crab ( $8.4 \%$ or 44.9 kg ) ranked third and forth, respectively, for this survey. Horseshoe crab biomass ( 146.4 kg ) for the fall
survey topped the list with $31.3 \%$, followed by long-finned squid (139.0 kg) with $29.7 \%$ of the total biomass. American lobster abundance for the second fall in a row was at a time series low, dropping another $30 \%$ this past fall. Boring sponge ranked forth with 40.4 kg . These top four species represent $79.2 \%$ of total invertebrate biomass in fall survey.

## Length Frequencies

Length frequency tables are provided primarily to give the reader an understanding of the size range of these species taken in LISTS. Lengths are converted to age frequencies for analysis of principal species such as scup, bluefish, striped bass, summer flounder, tautog, winter flounder, and weakfish. Changes such as an expansion in the size (age) range for some important recreational species are apparent in recent years including more large scup (Table 2.40-2.41), summer flounder (Table 2.44-2.45), and striped bass (Table 2.42-2.43).

Length frequencies were prepared for 19 species:

| alewife | spring and fall | 1989-2006 | Table 2.28; |
| :--- | :--- | :--- | :--- |
| American shad | spring and fall | $1989-2006$ | Table 2.29; |
| Atlantic herring | spring and fall | $1989-2006$ | Table 2.30; |
| Atlantic menhaden | fall | $1996-2006$ | Table 2.31; |
| black sea bass | spring | $1987-2006$ | Table 2.32; |
| blueback herring | spring and fall | $1989-2006$ | Table 2.33; |
| bluefish | spring and fall | $1984-2006$ | Table 2.34, Table 2.35; |
| butterfish | fall | $1986-1990,1992-2006$ | Table 2.36; |
| fourspot flounder | spring and fall | $1989-1990,1996-2006$ | Table 2.37; |
| hickory shad | spring and fall | $1991-2006$ | Table 2.38; |
| long-finned squid | spring and fall | $1986-1990,1992-2006$ | Table 2.39; |
| scup | spring and fall | $1984-2006$ | Table 2.40, Table 2.41; |
| striped bass | spring and fall | $1984-2006$ | Table 2.42, Table 2.43; |
| summer flounder | spring and fall | $1984-2006$ | Table 2.44, Table 2.45; |
| tautog | spring | $1984-2006$ | Table 2.46; |
| weakfish | spring and fall | $1984-2006$ | Table 2.47, Table 2.48; |
| windowpane flounder | spring | $1989,1990,1994-2006$ | Table 2.49; |
| winter flounder | April-May and fall | $1984-2006$ | Table 2.50, Table 2.51; |
| winter skate | spring | $1995-2006$ | Table 2.52. |

For the years where length data are available, length frequencies were prepared for the seasons or months for which the preferred indices of abundance and catch-at-age matrices are calculated; for some species length frequencies are provided for both seasons.

## Seasonal Indices of Abundance

The geometric mean count per tow was calculated from 1984-2006 for 38 finfish species plus lobster and long-finned squid (squid since 1986). All spring (April-June) and fall (September-October) data are used to compute the abundance indices presented in Tables 2.16 (spring) and 2.17 (fall), with the preferred seasonal index (for counts) denoted by an asterisk. Geometric mean biomass-per-tow indices have been calculated for 38 finfish and 15 invertebrate species (or species groups) since 1992, for both spring and fall (Table 2.18 and 2.19,
respectively). Age specific indices of abundance were calculated for specific important recreational species, including scup, striped bass, summer flounder, tautog, and winter flounder (see below). For two other species, bluefish and weakfish recruitment indices were calculated using modal analysis of the length frequencies. For each of the thirty-eight finfish species, plots including catch per tow in numbers and biomass in kilograms are illustrated in Figures 2.6 through 2.11. These figures also include plots of each of the age specific indices and recruitment indices mentioned above. Figure 2.12 provides plots of abundance (biomass) indices for crabs (1992-2006), American lobster (1984-2006), and long-finned squid (1986-2006).

Atlantic Sturgeon (fall, numbers per tow) and squid (spring, numbers per tow) were the only two species that are at recorded high abundance in 2006. Hickory shad were again abundant in Long Island Sound this past fall, dropping slightly from record highs in 2005. Several species were at record low or near record low abundance for both the spring and fall surveys. This includes seven spring species (i.e. where the spring survey provides better estimates of overall abundance); cunner, winter flounder, American lobster (spring and fall are both good estimates), fourbeard rockling, longhorn sculpin, sea raven, and little skate. Two other species, fourspot flounder and windowpane flounder, currently are at the second lowest abundance in the time series following their respective minimums in 2005. Atlantic herring additionally is listed as the second lowest abundance and has been below average for the past nine years. Four species having the preferred index during the fall have logged their respective lows in 2006. These species include; northern kingfish, American lobster, Spanish mackerel and American shad. In addition, striped searobin and weakfish are at near record lows; both recorded the second lowest value in their respective time series during 2006.

The absence of April data should be considered while analyzing spring 2006 catch and abundance information for various species since total catch and abundance could be skewed in one direction or the other. For example, long-finned squid abundance this past spring was at a record high abundance of 11.55 squid per tow. Squid do not show in LISTS catches typically until May and June, as noted with only 30 squid being taken in April since 2000, thus, not including the 40 April samples in the calculation will produce a unusually high estimate for this species. Calculating squid abundance and assuming no April catch in the time series produces an index of 4.40 squid per tow or slightly below average spring abundance. The other extreme is observed with two other species such as longhorn sculpin and sea raven that have the highest percent occurrence in April (Gottschall et. el., 2000). These two species indices were at a time series low in 2006, probably because no sampling occurred while they were still present in the Sound. The history of survey sampling intensity by month is presented in Table 2.4.

## Indices of Abundance: Important Recreational Species

Spring and fall abundance indices are presented in Tables 2.16-2.17. Indices of abundance at age were also calculated for seven important recreational species: bluefish (Table 2.20), scup (Table 2.21), striped bass (Table 2.22 age frequency, Table 2.23 index at age), summer flounder (Table 2.24), tautog (Table 2.25), weakfish (Table 2.26) and winter flounder (Table 2.27). Bluefish and striped bass indices-at-age are based on the fall and spring surveys, respectively, whereas winter flounder indices-at-age are based on only a portion of the spring survey (April-May). Two hundred and eighty-six (286) winter flounder collected and aged from LISTS 2006 were used for development of the age key and age matrix. Indices-at-age for tautog
are based on a combination of the spring and fall surveys and a pooled age key was used for the catch-at-age matrix (see methods). Both scup and weakfish indices-at-age are calculated and presented separately for each season. Five-hundred and seven scup were collected and aged in 2006 for use in age keys and calculations of the age matrix. Weakfish and bluefish use modal distributions for calculating their respective recruitment index although a small number of weakfish are taken each year for ageing purposes (see methods).

## Bluefish

The fall bluefish index dropped in 2005 to 18.89 fish/tow and again in 2006 to 15.66 fish/tow, after varying around the mean for the previous five years (Table 2.17, Figure 2.6). Average overall abundance for the time series is 24.80 fish/tow, and like weakfish, this index is composed of a high percentage of young-of year individuals that roughly make up about $70 \%$ of the bluefish catch. The 2006 young-of-year index of 12.43 fish/tow is also currently below the series average ( 17.13 fish/tow, Table 2.20). Higher abundances of age 0 fish were observed in 1997-1999, however, for the last seven years abundances have been at or slightly below average. A sixty-eight percent (68\%) drop in age 0 abundance occurred from the time series high (39.19/tow) in 1999 to 2006 (Table 2.20, Figure 2.6). Catches of age 1+ fish this past season ( 2.14 fish/tow) dropped sharply from a 21-year record high abundance (in numbers) and the second highest biomass index of age 1+ fish in 2004 ( 10.38 fish/tow, $13.96 \mathrm{~kg} / \mathrm{tow}$ ). The age $1+$ bluefish abundance ( $>29 \mathrm{~cm}$ ) increased by a factor of twelve from 1999, when a time series low was recorded ( $0.86 /$ tow $)$, to the anomalous high in 2004. At the inception of the survey, adult abundance increased to just above average levels in 1985 ( 3.56 fish/tow) then decreased steadily by $54 \%$ to 1.92 fish/tow in 1989. For the next three years, a large increase nearing record abundance levels was observed in 1992 (8.44/tow). The following seven years marked a declining trend to less than 76\% of average and the lowest abundance recorded in 1999.

## Scup

Scup abundance indices have increased by nearly an order of magnitude since about 1998 (Table 2.17, Figure 2.9). However, since 1999 abundance has been highly variable and changing between roughly 143 to 343 fish/tow from one year to the next. Excluding the exceptional, but short lived 1991 year class which produced an overall index of 311.6 fish/tow, fall abundance indices early in the survey time series (1984 through 1997) ranged between 10.7 (1984) and 92.5 fish/tow, averaging 52 fish/tow. Since 1998 the fall index has ranged from 103.3 (1998) to 537.7 (1999), averaging 297 fish/tow, almost than six times the pre-1998 average. High numbers of fish per tow result primarily from strong young-of year indices (1999-2002, 2004-2005), as high as 498 fish/tow in 1999 (Table 2.21). However, unlike the strong 1991 year class signal (291 fish/tow at age 0) which produced only one subsequent double-digit index (26.5 at age 1 in Fall 1992), several recent strong year classes have persisted at double digit strength through age 3 (2000, 2001 year classes) or age 4 (1999 year class) and have produced record abundance indices at age through at least age 6 .

Another very strong young-of-year index was recorded in 2005; the second highest in the time series. This cohort followed through in 2006 to the second highest age 1 index in the time series ( 51.02 fish/tow). Age two abundance in 2006, similarly, had an above average index with 9.52 fish/tow, however, for all older scup, with the exception of age 7, indices have dropped in the last year. Only two year classes, 2003 and 2006, stand out as weak to moderate recruitment in the last several years. The 2006 young-of-year index is at 52.16 fish/tow and is well below the
123.86 series mean. The 2003 year class also produced the lowest age 1 index in the last twelve years and the lowest age 2 index in the last six years.

The new scale of elevated scup abundance has also been apparent in the Spring survey. Spring indices of adult (age 2+) fish jumped from 2 to 21.7 fish/tow between 1999 and 2000, and have remained elevated since. During the spring 2002 survey, unusually high availability of scup resulted in an age $2+$ index of 208.8 fish/tow, almost 14 times the series average. Age 3 fish from the 1999 year-class were particularly abundant at 123.2 fish/tow. Spring age $2+$ indices in 2006 are currently at the second highest abundance observed at 40.57 fish/tow (Table 2.21, Figure 2.9). Additionally, this past year, ages 6 through 9 are at record high abundance for springtime sampling.

## Striped bass

Similar to scup, striped bass abundance in recent years has been highly variable. Three of the highest abundances were recorded during the spring of 1999, 2002, and 2005 (Table 2.16, Figure 2.11). Abundance during the first six years of the survey was relatively small, averaging only 0.03 fish/tow. Indications of a stock recovery first appeared in 1990 and during the next five years a moderate upward trend in abundance was observed, however in 1995 a $97 \%$ increase started the trend toward high abundance. Each year thereafter abundance increased in the Sound until 2000 and 2001 when LISTS started to observe decreases in abundance and 'jumpy’ indices (indices that jump up or down from one year to the next). Still, for the last 12 years abundance hasn't dipped below the series mean of 0.49 fish/tow. After the second spike in 2002, abundance again was followed by two years of decline. Currently, catch in numbers per tow dropped from the second highest in LISTS during 2005 ( 1.17 fish/tow) to ninth this past season ( 0.61 fish/tow). Overall abundance is still considered high and on average, over the last ten years, LISTS is capturing twelve times the number of stripers as it did in the first ten years of the survey. Since 1999, larger fish from 53 cm to 73 cm length have also been common during the spring and comprised $19 \%$ to $49 \%$ of the annual catch. Prior to the mid 1990's only 125 striped bass exceeding 52 cm in length were taken during the spring surveys. During 2006, the age structure was comprised predominately of three (25.8\%), four (15.5\%) and five year old fish (22.7) (Table 2.23). All indices-at-age for ages three through eleven in 2006 were above the respective averages for the time series. Contrary to the spring catch, LISTS fall sampling during 2006 produced a substantially higher index than a year earlier and is currently at second highest rank with 0.47 fish/tow (Table 2.17). Average fall abundance is 0.17 fish/tow for the series and 0.33 fish/tow in the last ten years.

## Summer flounder

Summer flounder rebounded from record low abundances in the early and mid-nineties and have shown above average fall survey abundance ( 1.89 fish/tow) for nine out of the last twelve years. Fewer summer flounder were seen in 2006 this past year ( 1.35 fish/tow) as the index dropped below the long-term average for the first time in eight years (Table 2.17, Figure 2.7). LISTS first observed a jump in abundance during the fall of 1996 to over 2 fish per tow. Abundance then hovered around this level for the next four years then increased in 2001 to 4.42 fish/tow. Summer flounder fall abundance peaked at 6.12 fish/tow in 2002 then dropped $45 \%$ in 2003 to 3.39 fish/tow and another $42 \%$ in 2004 to 1.95 fish/tow. Although the preferred fall index has declined sharply since 2002 (and is currently below the series average), abundance still remains about $32 \%$ above the average of the first twelve years of the survey (1984-1995).

Summer flounder have become more common in the spring survey since the mid-nineties when this increasing abundance trend began. Excellent springtime catches in 2003 resulted in record abundance and an index that exceeded the fall numbers. Spring abundance generally follows the same trend as the fall, with decreasing abundance in the last few years to a level that has dropped below the long-term average. Abundance during spring sampling is now reminiscent of the early nineties with the exception of older fish being seen in the catch in recent years.

Spring 2006 indices-at-age for age one through three dropped this year with each index being below the time series average (Table 2.24). Nonetheless, the one through three year old fish comprised $76 \%$ of the springtime catch in 2006. Age four fish during the spring are about average for the time series and age five and older fish are all above average. Fall indices-at-age showed an increase in young-of year fish this year with 0.98 fish/tow but dropped for ages 1 ( 0.22 fish/tow, ave 0.90 fish/tow) and age 2 ( 0.59 fish/tow, ave 0.66 fish/tow). Abundance for age one fish hasn't been this low since 1989 and, similarly, age two indices haven't been this low since 1995. LISTS is however still capturing some older fish as age 3 and older are all above the respective averages during the fall. This past fall, age one comprised $16.5 \%$, of the catch while age two was $45 \%$, and age three was $17.5 \%$ of the catch. The young-of-year summer flounder index ( $7.4 \%$ of the catch) has been variable throughout the fall time series and may be unreliable. Some of the benefits of higher abundance seen since the mid to late-nineties is the presence of older and larger fish in the population. Eight and nine year old fish are now represented in the age matrix; prior to 1997, the oldest fish were age 7 (Table 2.24). The length frequency distributions in Table 2.44 (spring) and Table 2.45 (fall) also illustrate this, with an increase in larger (>50 cm) fish captured in the past ten years during the spring (average 52 fish compared to 5 fish pre-1996) and fall surveys (average 29 fish compared to 9 fish pre-1996).

## Tautog

Tautog abundance has remained low for thirteen out of the last fourteen years. Tautog underwent a long-term decline from 1984 (2.75/tow) to 1995 (0.15/tow) and, although there was a gradual increasing trend from 1999 to 2002 up to average levels (0.79/tow), the last four years have remained about 28\% below average (Table 2.16, Figure 2.8). The 2006 abundance index is 0.64 fish per tow; up slightly from 2005. Although the fall is not considered the preferred index, the fall abundance this year ( $0.20 /$ tow) was similar to the spring in that it was $17 \%$ below the time series average (Table 2.17). The 2006 indices-at-age for all but age one, and ages four through six were below their respective averages for the time series (Table 2.25). This differed from just two years earlier when none were above their respective calculated averages. Tautog indices-at-age do not track age classes well because of low Survey catch and the overlap of ages at length. Another factor obscuring the catch-at-age matrix is that the age at full recruitment to both the survey gear and the fishery varies between ages 5 and 9 for this species (Johnson and Gottschall, 1999).

## Weakfish

One of the most significant changes in abundance seen during the 2006 fall survey was with weakfish. A ninety-four percent (94\%) drop in abundance ( 1.50 fish/tow, Table 2.17) was recorded this fall, mostly from the age 0 weakfish being absent from LISTS catches (Table 2.26). Age 0 weakfish usually dominate the overall index and have been very abundant in the fall over the last seven years. Although weakfish young-of-year abundances had been high from 19992004 (Table 2.26, Figure 2.11), the abundance dropped by more than $50 \%$ in 2005 and again this
year to only $5.5 \%$ of the 1984-2005 mean (18.94/tow). A strong year class in 2000 drove the overall index to double, reaching a record 63.42 fish per tow. Although the next year class in 2001 caused the overall index to drop to 40.51 fish/tow, abundance for the following three years saw moderate increases up to the second most abundant year, reaching 59.07 fish/tow in 2004 (Tables 2.17 and 2.26, Figure 2.11). The Age 0 catches between 1999 and 2004 ranged from 30.93 fish/tow (1999) to 63.31 fish /tow (2000) and are unprecedented in the time series. The average catch/tow of age 0 fish prior to 1999 was 7.12 fish/tow. Weakfish age $1+$ abundance during the fall has generally fallen since the three years of peak abundance observed between 1995 and 1997. From 2002 through 2005, age $1+$ abundance in the fall remained about $50 \%$ lower than average, however, in 2006 this index rose to about average levels ( 0.29 fish/tow). Similarly, springtime abundance of age $1+$ weakfish had remained at roughly three times higher than the average (1997-1999) before declining to 0.04 fish/tow in 2003 (the lowest since 1994). This past spring, LISTS again recorded about average abundance at 0.14 fish/tow.

## Winter Flounder

Winter flounder generally has had a decreasing trend in abundance since 1996. LISTS has seen lower than normal catches in thirteen of the last fifteen years. The overall winter flounder spring (April-June) index for 2006 (7.50/tow) is the lowest in twenty-three years of LISTS sampling and is currently only $11 \%$ of the long term mean of $66.67 /$ tow (Table 2.16). Average catches for the first ten years of the survey were 94 winter flounder per standard tow. A customized winter flounder index (Table 2.27) that uses aged fish from April and May samples (used to develop indices of abundance at age) is at a historic low with only 5.59 fish/tow being recorded. This index fell for the fifth straight year in 2006. This season's index is the eighth year of low abundance (Table 2.27, Figure 2.7) and illustrates why fisheries managers are concerned about the status of this species. During the beginning of the time series a slight drop in abundance was observed in 1985 and 1986 to just below average levels in 1986 (63.65/tow). This was followed by increasing abundance for the next four years to the height of winter flounder abundance in 1990 (223.09/tow). This period of high winter flounder abundance was short lived as abundance dropped $72 \%$ during the next two years to 61.39 fish per tow in 1992. From 1992 through 1995, abundance varied at or below average levels, however, 1996 showed a more than two-fold increase to 110.62 fish per tow. Since 2001 abundance generally has decline to the current low level.

Only the age-0 index, obtained from the Estuarine Seine Survey (Job 2, Part 2), shows a notable increase in abundance between 2003 and 2005. However, this also was short lived as the 2006 index of 0.74 fish per haul is now at a minimum for the nineteen-year time series. From its second lowest value in 2001, the age 0 index rose to average in 2003 ( 8.07 fish per haul), then increased $35 \%$ in 2004 to 10.96 fish per haul: the highest this index attained since 1996. This year that index dropped to only $11.5 \%$ of average fish per haul for this survey. The single notable increase from mature fish this year comes from age three fish (up $30 \%$ to 1.10 fish per tow) originating from the 2003 year class. This year class also produced an increase in age 2 fish in 2005 (59\%) and age 1 fish in 2004 (156\%). The LISTS age 4+ winter flounder index, however, continues to fall and is currently at 0.74 fish per tow. The age $4+$ abundance currently is at the lowest level in the twenty-three years of the survey and for the past five years, the age 4+ indices have deteriorated to less than 10 fish per tow. The $4+$ index was at its height at the start of the survey in 1984 (27.91/tow) then declined through 1988 to stable and average abundance (around 13.10/tow) for the next three years. Dropping abundance followed, and
during 1995 the lowest observed catch/tow (2.31) at the time was recorded. An unusual increase in abundance occurred in 1996 (15.92/tow) and for the next five years it fluctuated around average levels. The high age 4+ indices from 1996-2001 are probably a result of the strong 1992 and 1994-1996 year classes.

## MODIFICATIONS

None.

## NARROWS

## Methods

The sample design in the Narrows relies upon stratified fixed sites. Initially sites were randomly selected by strata, however, this approach was modified in favor of fixed sites. Typically, this area is so heavily fished by lobstermen that there isn't sufficient area free of pot gear in which to tow the research trawl. In an attempt to reduce gear conflicts and avoid known bottom hangs while still representatively sampling this relatively small area (approximately 240 $\mathrm{km}^{2}$ ), site selection evolved from ten stratified random sites during the spring of 2000 to six fixed sites starting in the fall of 2000. Six sites yield a sampling intensity of about one site per $40 \mathrm{~km}^{2}$, which is a higher sampling intensity than LISTS (1:68 $\mathrm{km}^{2}$ ). Five years of sampling in the Narrows showed comparable overall species richness and abundances in the Narrows as compared to LISTS (Gottschall and Pacileo 2005), therefore, since 2005 the number of sites to be sampled in the Narrows has been reduced to three sites per month with a resultant sampling intensity of $1: 80 \mathrm{~km}^{2}$.

Sampling gear and procedures for the Narrows survey are the same as described for LISTS with one exception, all finfish species collected in the Narrows samples are measured. Although data for these additional sites in the Narrows are collected and analyzed in the same manner as for the LISTS sites, the data are managed and analyzed separately to maintain consistency within the LISTS database.

To compare finfish abundance in the Narrows to other areas of the Sound with similar habitat characteristics, a micro-habitat analysis was initiated using statistical (SAS) and geographic (ESRI ArcView) software to analyze the substrate type underlying the actual path of the research vessel for all LISTS and Narrows tows where continuous position information was recorded. In 1984, when the Long Island Sound Trawl Survey (LISTS) strata designations were developed, the initial bottom type designation for each $1 \mathrm{x} 2 \mathrm{n} . \mathrm{mi}$. site box in the LISTS site grid was based on information from Reid et al. (1979). The same interpretation of the sediment data published in 1979 was used to assign bottom types for the Narrows site boxes in 1999. This micro-habitat analysis will rely on updated sediment information (Poppe et al. 2000) to determine bottom types along the actual towpath for each sample. Data files were converted into geographic information system (GIS) layers and new sediment types assigned following procedures described in Gottschall and Pacileo (2006).

## Results and Discussion

## Summary of Catches in Narrows

During 2006, 9 tows were conducted at three fixed sites in the far western section of Long Island Sound known as the Narrows (Table 2.53). The Narrows were sampled each month of the standard LISTS (May, June, and September), generally after the standard sample sites for each month's cruise had been completed. As explained previously, neither April nor October sampling was conducted this year (see Overview of LISTS 2006 Spring and Fall Surveys section in this report).

Twenty-seven (26) finfish and 16 invertebrate species were captured from the Narrows (Table 2.54). Butterfish was the most abundant finfish by number $(12,977)$ and by weight $(438.3$
kg ). Scup was the second most abundant by number $(2,852)$ and by weight $(359.5 \mathrm{~kg})$. Combined, these two species accounted for $89 \%$ of the catch by number and $68.6 \%$ of the biomass. During the spring, 29 species were observed and a total of 2,817 fish ( 659.6 kg ) were captured, whereas, during the fall, 21 finfish species were observed and a total of 20,443 finfish ( 538.0 kg ) were captured (Table 2.55). Spring catches were dominated by Atlantic herring, winter flounder and butterfish ( $74.9 \%$ of the catch by number) and striped bass accounted for most of the biomass even though only 131 were caught. By comparison, scup dominated the fall catches by number (77.6\%) and weight (42.6\%).

The bulk of the invertebrate biomass recorded in the Narrows in 2006 was horseshoe crabs ( 20 crabs, $43.5 \%$ of the catch by weight). Although more American lobsters were caught (41), they only accounted for $11.5 \%$ of the invertebrate biomass. Since regular sampling began in the Narrows in 2000, horseshoe crab and American lobster have been the two most abundant invertebrate species (by weight), except in 2006. This past year, although horseshoe crab was still the most abundant invertebrate, lobster abundance only ranked fourth. Long-finned squid, typically one of the top two invertebrate species by number, was the most abundant invertebrate by number (304) again in 2006, even though it accounted for a small amount of the biomass ( $9.7 \%$ ). When the catch is broken out by season, we can see that both lobster and horseshoe crab abundance in the spring fell below the biomass recorded for rock crab and hydroid spp. in 2006 (Table 2.56). Fall catches were dominated by horseshoe crab and long-finned squid, accounting for $94.4 \%$ of the biomass.

Species richness (measured as the mean number of species per tow) is one way to compare general ecosystem health for the Narrows with the rest of Long Island Sound if one equates diversity with a healthy ecosystem. The general trends described previously (Gottschall and Pacileo, 2007, and Gottschall and Pacileo, 2006) continued in 2006. Overall, the species richness values were fairly similar, both among years and between surveys (Table 2.57). When the lobster die-off occurred in the late 1990's, there was concern that whatever factors had reduced lobster abundance would disproportionately affect the Narrows. There is little indication of reduced finfish species richness in the Narrows versus the rest of the Sound. In fact, in six of the past seven spring surveys ( $86 \%$ ), and four of seven fall surveys ( $57 \%$ ), finfish species richness has been slightly greater in the Narrows than in LISTS samples. On the other hand, invertebrate species richness tends to be lower at Narrows sites than in the rest of the Sound, particularly in the fall (only once in seven years has the invertebrate diversity been higher in the Narrows in the fall). Finfish species richness is generally higher in the fall for both surveys. However, invertebrate species diversity, while usually higher in the fall for the LISTS survey, was lower in the fall Narrows survey for five of the seven years (71\%). Lower species richness during the fall in the Narrows may be hypoxia related. Kaputa and Olsen (2000) documented dissolved oxygen concentrations decline from east to west in LIS, with the lowest levels occurring in the Narrows in the late summer.

For the majority of finfish species monitored with indices of abundance (geometric mean count/tow) in LISTS, springtime abundance trends for the time series (2000-2006) have been similar between the LISTS and Narrows surveys (Tables 2.16 and 2.58, respectively). For example, tautog indices show virtually the same pattern of increasing abundance (2000-2002), followed by a decline in 2003 and then some slight improvement to 2005. Black sea bass is another example of similar abundance patterns in the two surveys, with an increase 2000-2002, followed by a decline in 2003. Since 2003, however, abundance has continued to drop in LISTS
while remaining steady in Narrows. Other species show similar patterns in the indices but are more abundant in the Narrows than in LISTS; namely cunner, fourspot flounder and fourbeard rockling. The species that tend to have higher indices in LISTS are also those that tend to be caught in the eastern part of LIS during April-June LISTS sampling, such as northern searobin, little skate, spiny dogfish and sea raven. One species with a notable difference in abundance trends between the surveys is winter flounder. Although the LISTS index was higher than Narrows in 2000, since then winter flounder have declined continuously in LISTS (2001-2006) while indices have increased fourfold in the Narrows.

Indices of abundance for finfish in the fall tend to be higher in Narrows than in LISTS (Tables 2.58 and 2.17, respectively). This is true for bluefish, butterfish, spotted hake, menhaden, moonfish, striped searobin, scup and weakfish. For a couple species, fall indices of abundance are higher in LISTS but still show similar trends as the indices in Narrows. Examples would be smooth dogfish, summer flounder, blueback herring (except for 2005), hogchocker, and squid. One notable difference between fall indices in the Narrows versus indices in LISTS is the higher frequency of unusually large indices in some years, although this may be an artifact of the much smaller sample size in the Narrows (3-12 tows/yr) as compared to LISTS (40-80 tow/yr).

Seasonal biomass indices (geometric mean kg per tow) for a number of invertebrate species (Tables 2.18-2.19 and 2.60, for LISTS and Narrows data, respectively) show similar trends in abundance for many species. Of particular interest is whether epibenthic invertebrates (like lobsters and crabs) show similar trends between the surveys (Figure 2.13). Although individual annual index values vary a bit, the overall trends in American lobster biomass indices have shown a marked decline in both Spring Surveys (2000-2006) by a factor of 4.6; from 3.90 $\mathrm{kg} /$ tow to $0.84 \mathrm{~kg} /$ tow in LISTS (Table 2.18) and from $4.06 \mathrm{~kg} /$ tow to $0.88 \mathrm{~kg} / \mathrm{tow}$ in Narrows (Table 2.60). Fall lobster indices have also followed the same declining trend of roughly the same magnitude in both surveys, except for two years (2003-2004) when the biomass per tow recorded in the Narrows showed a promising increase that was short-lived (Tables 2.19 and 2.60 for LISTS and Narrows data, respectively). Blue crab abundance (2000-2006) has been relatively low and stable in the spring in both LISTS ( $0.0-0.04 \mathrm{~kg} / \mathrm{tow}, 2000-2006$ ) and Narrows surveys ( $0.0-0.03 \mathrm{~kg} /$ tow) except for one increase in Narrows 2002 to $0.08 \mathrm{~kg} /$ tow. In the fall, the Surveys again show similar trends, albeit decreasing from highs in 2000 to consistently low levels 2003-2006. Spring spider crab indices also show some similarities between the Surveys; increasing from 2000-2004, then dropping sharply for 2005 \& 2006. Rock crab indices are quite similar for the spring 2000-2005 period but then show a divergence in 2006 with abundance increasing threefold to its highest level in the Narrows but remaining low in LISTS. Fall biomass indices for rock crabs also show similar patterns between the Surveys from 2000 to 2004 but then diverge with abundance in the Narrows increasing substantially while abundance in LISTS remains low.

## Micro-Habitat Analysis

New sediment types have been determined for all tows with usable position data (20002006) in both LISTS and Narrows surveys (resultant sample sizes of 1,279 tows and 166 tows, respectively). To determine whether the new sediment types will help explain more of the
variability in catches between LISTS and Narrows, analysis of variance procedures (SAS PROC GLM) were performed. The Duncan Multiple Range Test option was used to test for differences in mean natural log catches by different sediment classifications. Preliminary results for three species, American lobster, winter flounder and scup (porgy), are presented here.

Since American lobster is an epibenthic invertebrate, one would expect survey catches to be different over different bottom types, and in fact the difference between catches is significantly different over different bottom types. The Reid et al. (1979) sediment classifications for each site box account for roughly 35\% of the variability in the standard LISTS catches ( $\mathrm{P}<0.0001, \mathrm{R}^{2}=0.3473, \mathrm{df}=2,1278$ ) versus only $7 \%$ of the variability in the Narrows catches ( $\mathrm{P}=0.0008, \mathrm{R}^{2}=0.0659$, $\mathrm{df}=1,165$ ). By comparison, the Poppe et al (2000) sediment classifications at three points along each towpath account for $33-39 \%$ of the variability in the catches ( $\mathrm{P}<0.0001-0.02, \mathrm{R}^{2}=0.3264-0.3895$, $\mathrm{df}=6,1250$ ) but show a much weaker relationship to the lobster catches in the Narrows ( $\mathrm{P}<0.0001-0.1045, \mathrm{R}^{2}=0.0277-0.2430, \mathrm{df}=2,163$ ). For the Reid classifications, a Duncan multiple range test ( $\mathrm{p}=0.05$ ) showed there are significant differences in the LISTS catches over each of three bottom types (mud, transition or sand) with the highest catches occurring over mud bottom and the lowest catches occurring over sand bottom. For the Poppe classifications, a Duncan multiple range test ( $p=0.05$ ) showed more overlap between the mean LISTS catches over different bottom types with the softest three sediment types producing significantly higher catches than the hardest four sediment types.

Mean catches over different bottom types were also compared for winter flounder, a vertebrate with close association with the bottom and, consequently, one would expect to see significant differences in the catches of winter flounder related to bottom type. However, the Reid sediment classifications account for roughly $10 \%$ of the variability in the standard LISTS catches ( $\mathrm{P}<0.0001, \mathrm{R}^{2}=0.1035$, $\mathrm{df}=2,1278$ ) and were not significantly related to variablity in the Narrows catches ( $\mathrm{P}=0.6351, \mathrm{R}^{2}=0.0014$, $\mathrm{df}=1,165$ ). By comparison, the Poppe sediment classifications account for only $7 \%$ of the variability in LISTS catches ( $\mathrm{P}<0.0001, \mathrm{R}^{2}=0.0685-$ $0.0696, \mathrm{df}=6,1250$ ) and, similar to the Reid classifications, do not show a significant relationship to Narrows catches of winter flounder.

Similar statistical analyses for mean catches of scup (porgy) over different bottom types, using both Reid and Poppe classifications, were significant only for the Reid classifications in LISTS catches ( $\mathrm{P}<0.0001, \mathrm{R}^{2}=0.0291, \mathrm{df}=2,1278$ ). Tows over sand produced significantly less scup but there was no significant difference between tows over mud and transition bottom types. There were no significant relationships between the Poppe classifications and LISTS catches, nor between either classification method and Narrows catches of scup.

Relationships between catch and bottom sediment types are expected to be very speciesspecific and further analyses with additional specie are planned. Depth is also a large component of habitat utilization patterns and it is expected to have an impact on trawl survey catches. Future work will include assigning updated depth information to the same three points along each towpath that now have updated sediment types. Statistical procedures will be run against both updated depth and sediment type to determine to what extent these variables account for differences between LISTS and Narrows catches, or even if they account for more variability in the catches within a survey than the old sediment or depth classifications.

TABLES 2.1-2.27
LISTS

Table 2.1. Specifications for the Wilcox 14 m high-rise trawl net and associated gear.

| Component | Description |
| :--- | :--- |
| Headrope | 9.1 m long, 13 mm combination wire rope |
| Footrope | 14.0 m long, 13 mm combination wire rope |
| Sweep | Combination type, 9.5 mm chain in belly, 7.9 mm chain in wing |
| Floats | 7 floats, plastic, 203 mm diameter |
| Wings | 102 mm mesh, \#21 twisted nylon |
| Belly | 102 mm mesh, \#21 twisted nylon |
| Tail Piece | 76 mm mesh, \#21 twisted nylon |
| Codend | 18.2 mm long, $6 \times 7$ wire, 9.5 mm diameter |
| Ground Wires | top legs 27.4 m long, $6 \times 7$ wire, 6.4 mm diameter |
| Bridle Wires: | 27.4 m long, $6 \times 7$ wire, 11.1 mm, rubber disc type, 40 mm diameter |
| Bottom Legs | Steel "V" type, 1.2 m long x 0.8 m high, 91 kg |
| Doors | $6 \times 77 \mathrm{wire}, 9.5 \mathrm{~mm}$ diameter |
| Tow Warp |  |

Table 2.2. The number of sites scheduled for sampling each month within the 12 depth-bottom type strata.

|  | Depth Interval (m) |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Bottom type | $\mathbf{0 - 9 . 0}$ | $\mathbf{9 . 1 - 1 8 . 2}$ | $\mathbf{1 8 . 3 - 2 7 . 3}$ | $\mathbf{2 7 . 4 +}$ | Totals |
| Mud | 2 | 3 | 5 | 5 | 15 |
| Sand | 2 | 2 | 2 | 2 | 8 |
| Transitional | 3 | 5 | 5 | 4 | 17 |
| Totals | $\mathbf{7}$ | $\mathbf{1 0}$ | $\mathbf{1 2}$ | $\mathbf{1 1}$ | $\mathbf{4 0}$ |

Table 2.3. Length and age data collected in 2006.
In addition to the species listed below, other rarely occurring species (totaling less than 30 fish/year each) were measured. During 2006, nineteen other species were measured during LISTS sampling as either rarely occurring species or for other research related projects

| Species measured | Measurement | \# tows/day | \# fish measured |
| :---: | :---: | :---: | :---: |
| Alewife | FL (cm) | All | min of 15 / tow |
| American lobster | CL ( 0.1 mm ) | All | min of 50 / tow |
| American shad | FL (cm) | All | min of 15 / tow |
| Atlantic herring | FL (cm) | All | min of 15 YOY and min of 30 adults / tow |
| Atlantic menhaden | FL (cm) | All | min of 15 / tow |
| Atlantic sturgeon | FL (cm) | All | All |
| blueback herring | FL (cm) | All | min of 15 / tow |
| bluefish | FL (cm) | All | min of $30 \mathrm{YOY} /$ tow, all adults |
| black sea bass | TL (cm) | All | All |
| butterfish | FL cm) | $1^{\text {st }}-3^{\text {rd }}$ | min of 15 YOY and 15 adults / tow |
| cunner | TL (cm) | All | All |
| dogfish, smooth | FL (cm) | $1^{\text {st }}-3^{\text {rd }}$ | All |
| dogfish, spiny | FL (cm) | All | All |
| fourspot flounder | TL (cm) | $3^{\text {rd }}$ on | min of 30/tow |
| hickory shad | FL (cm) | All | All |
| horseshoe crab | PW (cm) | All | All |
| northern searobin | FL (cm) | $3^{\text {rd }}$ on | min of $30 /$ tow |
| moonfish | FL (cm) | Occasional | min of $10 /$ tow |
| smallmouth flounder | TL (cm) | Occasional | min of 10/tow |
| striped bass | FL (cm) | All | All |
| striped searobin | FL (cm) | $3^{\text {rd }}$ on | min of 30/tow |
| scup | FL (cm) | All | min of 15 YOY and 30 / mode for age 1+ |
| long-finned squid | ML (cm) | $1^{\text {st }}-3^{\text {rd }}$ | min of 30 / tow |
| summer flounder | FL (cm) | All | All |
| tautog | TL (cm) | All | All |
| weakfish | FL (cm) | All | min of $15 \mathrm{YOY} /$ tow, all adults |
| windowpane flounder | TL (cm) | $1^{\text {st }}-3^{\text {rd }}$ | min of 50 / tow |
| winter flounder | TL (cm) | All | min of 100 / tow |
| winter skate | TL (cm) | All | All |

| Species aged | Structure | Subsample |
| :---: | :---: | :---: |
| scup | scales | Collected every month. For each month scales are taken from the following: 3 fish/cm $<20 \mathrm{~cm}$; $5 / \mathrm{cm}$ from $20-29 \mathrm{~cm}$; and all fish $>30 \mathrm{~cm}$. |
| summer flounder | scales | all fish $>=60 \mathrm{~cm}$ |
| tautog | opercular bones | Collected from a minimum of 200 fish/year. |
| weakfish | scales / otoliths | Collected each season. For each season, 1 scale and one otolith sample / cm up to 19 cm and all scales and otoliths $>=20 \mathrm{~cm}$. |
| winter flounder | otoliths | Collected during April and May from two areas in the Sound: eastern-central and western. For each month and area, subsamples are taken as follows: in the easterncentral area 7 fish / cm $<30 \mathrm{~cm}, 14 / \mathrm{cm}$ from $30-36 \mathrm{~cm}$, all fish $>36 \mathrm{~cm}$. In the western area 5 fish $/ \mathrm{cm}<30 \mathrm{~cm}, 10 / \mathrm{cm}$ from $30-36 \mathrm{~cm}$, all fish $>$ than 36 cm . |

Notes: min = minimum; YOY = young-of-year; $F L=$ fork length; $T L=$ total length; $C L=$ carapace length; $M L=$ mantle length; $P W=$ prosomal width.

Table 2.4. Number of Long Island Sound Trawl Survey (LISTS) samples taken by year and cruise
In 1984, thirty-five sites per monthly cruise from April through November were scheduled for sampling. Starting in 1985, forty sites per cruise were scheduled. In 1991, the Trawl Survey was modified to a spring (April - June) and fall (September - October) format--July, August and November sampling was suspended. In 1993 and 1994, an additional cruise of 40 sites was added to the fall period. The additional fall cruise was suspended in 1995. One hundred twenty tows were conducted in 2006 due to delays in rebuilding the main engine on the R/V John Dempsey (spring) and mechanical failure/overhaul of the hydraulic power take-off (fall).

| Cruise | Year |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 2.9. Data requests by month, 2006.

| MONTH | REQUEST | ORGANIZATION OR PURPOSE |
| :---: | :---: | :---: |
| January | tautog count \& biomass indices and catch at length | Uconn |
|  | winter flounder indices at age | Dominion Annual Report |
|  | scup indices at age, biomass indices and length frequencies | ASMFC Technical Committee |
|  | weakfish indices ( $0,1+$ ) | ASMFC Technical Committee |
|  | maps of bottom temperatures in LIS (from LISS) | for Fishery Advisory Council |
|  | maps of horseshoe crab survey sites and bird info | for meeting with concerned citizens and Nature Cons |
|  |  |  |
| February | tow info for tows where windowpane flounder were measured | NEFMC |
|  | All trawl tow records (SP,SU,FA,WI,LT) | NEFMC |
|  | spiny dogfish indices, lengths and length frequencies by season | NMFS |
|  | black sea bass indices and length frequencies | NMFS |
|  | summer flounder indices, indices at age and length frequencies | NMFS |
|  | Atlantic herring indices | ASMFC Compliance Report |
|  | winter flounder catch at age and length frequencies | ASMFC Technical Committee |
|  |  |  |
| March | Summer Survey tow data | NEFMC |
|  |  |  |
| April | LISTS sampling grid and site info | NY DEC staff |
|  | bluefish indices | ASMFC Compliance Report |
|  | menhaden indices | ASMFC Compliance Report |
|  |  |  |
| May | tautog indices at age | ASMFC Technical Committee |
|  | tautog indices | ASMFC Compliance Report |
|  |  |  |
| July | maps of beam trawl survey grid | for DEP project documentation |
|  | tautog catch at age matrix | ASMFC Technical Committee |
|  |  |  |
| August | skates (all species) count and weight indices | NMFS |
|  |  |  |
| September | river herring count \& weight indices and length freqs | Environmental Defense Org |
|  | maps of proposed closed areas for horseshoe crab | for public hearing |
|  |  |  |
| October | skates (various species) counts and indices | NMFS |
|  | winter flounder indices | ASMFC Compliance Report |
|  |  |  |
| November | count data 2000-2006 for eastern LIS | NMFS |
|  | indices and counts from LISTS and Narrows for Status Report | DEP / EPA |
|  | tautog indices | ASMFC Public Hearing |
|  | cunner counts and indices | Queens College research on cormorant feeding habits |
|  | maps of LIST catches of potential prey items for terns | for meeting with FWS |
|  |  |  |
| December | SFL indices at age using NMFS and LISTS data | NMFS / ASMFC |

Table 2.10. Sample requests by month, 2006.

| MONTH | REQUEST | ORGANIZATION OR PURPOSE |
| :---: | :---: | :---: |
| May | Loligo paeleii tentacles | NMFS Woods Hole - Loligo DNA Study |
|  | misc critters for biology class | Illing Middle School |
|  | squid for dissection class | Illing Middle School |
|  | butterfish \& whiting for dissection class | Putnam High School |
|  | collected various species for fish isotope study re: cormorant food habits | Yale graduate student |
|  | striped bass and bluefish | EPA-residual chemical tissue analyisis (e.g. PCBs) |
|  |  |  |
| June | collected various species for fish isotope study re: cormorant food habits | Yale graduate student |
|  | striped bass and bluefish | EPA-residual chemical tissue analyisis (e.g. PCBs) |
|  |  |  |
| September | specimens of various species for teaching class on Biology of Fishes | Ecology and Evolutionary Biology, UCONN |
|  | squid for dissection class | SCSU |
|  | striped bass and bluefish | EPA-residual chemical tissue analyisis (e.g. PCBs) |
|  | scup, bluefish, summer flouner and lobster | EPA/NCA-tissue contaminant analysis |
|  |  |  |
| October | specimens for teaching class on Biology of Fishes | Ecology and Evolutionary Biology, UCONN |
|  | striped bass and bluefish | EPA-residual chemical tissue analyisis (e.g. PCBs) |
|  | scup, bluefish, summer flouner and lobster | EPA/NCA-tissue contaminant analysis |
|  | lobster for dissection class | SCSU |
|  | squalus specimens requested: none provided $\mathrm{b} / \mathrm{c}$ done sampling for yr | Ecology and Evolutionary Biology, UCONN |

Table 2.11. List of finfish species observed in 2006.
Forty-nine species were observed in 2006. (No new species were observed in 2006). Since 1984, ninety-six species of finfish have been identified in LISTS (see Appendix I for the full list of species).

| Common Name | Scientific Name | Common Name | Scientific Name |
| :--- | :--- | :--- | :--- |
| anchovy, bay | Anchoa mitchilli | jack, yellow | Caranx bartholomaei |
| black sea bass | Centropristes striata | lizardfish, inshore | Synodus foetens |
| bluefish | Pomatomus saltatrix | menhaden, Atlantic | Brevoortia tyrannus |
| bonito, Atlantic | Sarda sarda | moonfish | ocean pout |
| butterfish | Peprilus triacanthus | pipefish, northern | Macrozoarces americanus |
| cunner | Tautogolabrus adspersus | pollock | Syngnathus fuscus |
| dogfish, smooth | Mustelus canis | rockling, fourbeard | Pollachius virens |
| dogfish, spiny | Squalus acanthius | sand lance, American | Enchelyopus cimbrius |
| filefish, planehead | Monacanthus hispidus | Ammodtes americaus |  |
| flounder, fourspot rough | Trachurus lathami |  |  |
| flounder, smallmouth | Paralichthys oblongus | scup | Stenotomus chrysops |
| flounder, summer | Etropus microstomus | searobin, northern | Prionotus carolinus |
| flounder, windowpane | Paralichthys dentatus | Prionotus evolans |  |
| flounder, winter | Scophthalmus aquosus | shad, hickory | Alosa sapidissima |
| flounder, yellowtail | Pseudopleuronectes american | Pleuronectes ferrugineus | skate, clearnose |

Names taken from: Common and Scientific Names of Fishes from the United States, Canada and Mexico, American Fisheries Society, Sixth ed., 2004.

Table 2.12. List of invertebrate species observed in 2006.
In 2006, thirty-eight invertebrate species were identified. In most cases, invertebrates are identified to species; however, species that are very similar are identified to genus, and in difficult cases, to a higher taxon.

| Common Name | Scientific Name | Common Name | Scientific Name |
| :--- | :--- | :--- | :--- |
| arks | Noetia-Anadara spp. | mussel, blue | Mytilus edulis |
| bryozoan, bushy | Phylum Bryozoa | northern moon snail | Lunatia heros |
| bryozoan, rubbery | Alcyonidium verrilli | sea grape | Molgula spp. |
| clam, hard clams | Artica-Mercinaria-Pitar sp. | sea urchin, purple | Arbacia punctulata |
| clam, surf | Spisula solidissima | shrimp, brown | Penaeus aztecus |
| coral, star | Astrangia poculata | shrimp, ghost | Gilvossius setimanus |
| crab, mud | Family Xanthidae | shrimp, mantis | Squilla empusa |
| crab, Japanese shore | Hemigrapsus sanguineus | shrimp, northern red | Pandalus montagui |
| crab, blue | Callinectes sapidus | shrimp, sand | Crangon septemspinosa |
| crab, flat claw hermit | Pagurus pollicaris | slipper shell, common | Crepidula fornicata |
| crab, horseshoe | Limulus polyphemus | sponge spp. | sponge spp. |
| crab, lady | Ovalipes ocellatus | sponge, boring | Cliona celate |
| crab, rock | Cancer irroratus | sponge, deadman's fingers | Haliclona spp. |
| crab, spider | Libinia emarginata | sponge, red bearded | Microciona prolifera |
| cyclocardia | Cyclocardia borealis | squid, long-finned | Loligo pealeii |
| hydroid spp. | Tubularia spp. | starfish spp. | Asteriid spp. |
| jelly, moon | Aurelia aurita | whelk, channeled | Busycotypus canaliculatus |
| jellyfish, lion's mane | Cyanea capillata | whelk, knobbed | Busycon carica |
| lobster, American | Homarus americanus | worms, fan | Myxicola infundibulum |

Names taken from: A Field Guide to the Atlantic Seashore, Peterson Field Guide Series, 1978 (Gosner, 1978).

Table 2.13. Total number and weight (kg) of finfish and invertebrates caught in 2006.
Finfish species are in order of descending count. Invertebrate species are in order of descending weight (nc $=$ not counted). Young-of-year bay and striped anchovy are neither separated by species or quantified; young-of-year Atlantic herring are not quantified. Number of tows (sample size)=120.

| species | count | \% | weight | \% | species | count | \% | weight | \% |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 2.16. Spring indices of abundance for selected species, 1984-2006.
The geometric mean count per tow was calculated for 38 finfish and 2 invertebrates using April-June data. An asterisk next to the species name and time series mean, indicates that the spring index is a better estimate than the fall index (Simpson et al. 1991). Two asterisks indicate that both the spring and the fall indices provide good estimates.

|  | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  | 84-05 <br> Mean |

Table 2.17. Fall indices of abundance for selected species, 1984-2006.
The geometric mean count per tow was calculated for 38 finfish and 2 invertebrates using September-October data. An asterisk next to the species name and a time series mean, indicates that the fall index provides a better estimate than the spring index (Simpson et al. 1991). Two asterisks indicate that both the spring and the fall indices provide good estimates.

Table 2.18. Finfish and invertebrate biomass indices for the spring sampling period, 1992-2006.
The geometric mean weight (kg) per tow was calculated for 38 finfish and 15 invertebrate species for the spring (AprilJune) sampling period.

Table 2.19. Finfish and invertebrate biomass indices for the fall sampling period, 1992-2006.
The geometric mean weight (kg) per tow was calculated for 38 finfish and 15 invertebrate species for the fall (Sept-Oct) sampling period.

|  | Fall |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 2.20. Bluefish indices of abundance, 1984-2006.
Using September and October length data, the geometric mean catch per tow was calculated for two age groups of bluefish: age-0 and all fish age 1 and older. Age-0 was defined as bluefish less than 30 cm fork length.

| Year | Fall |  |  |  |
| :---: | :---: | :---: | :---: | :---: |

Table 2.21. Scup indices-at-age, 1984-2006.
Spring (May and June) and fall (September and October) catch and age data were used to determine the geometric mean indices-at-age ${ }^{1}$. The spring and fall age keys were used to expand length frequencies to age frequencies and then the spring and fall overall indices were proportioned by the percentage of fish in each age. The $0-10+$ index represents the overall index (sum of ages 0-10+), and the adult $2+$ index is provided as the sum of ages 2-10+ index. All fish older than age 9 were included in the age $10+$ index ${ }^{2}$.

| Year | Spring (May-June) |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

(1) In 1984, 1985, 2003, 2004, and 2006 less than the number of scheduled tows were conducted in some months: in 1984, thirteen tows were conducted in May and nineteen in June; in 1985, five tows were conducted in June; in 2003, the 40 scheduled October tows were conducted in November and thus dropped; in 2004, thirty-nine tows were conducted in June; and in 2006, twenty tows were conducted in September and twenty tows were conducted in early October (see Table 2.4).
(2) A total of six fish were taken age 10+, all of which were taken between 1984 and 1988. The oldest fish aged was a 14-year-old taken in 1985.

Table 2.22. Age frequency of striped bass taken in spring, 1984-2006.
Ages were derived from trawl survey length data using the average of Hudson River and Chesapeake Bay von Bertalanffy parameters (Vic Crecco, pers. comm.).

Note: number of fish taken but not measured = one in 1984, one in 1988, two in 1990.

Table 2.23. Striped bass indices-at-age, 1984-2006.
Spring length data was converted to ages using the average of Hudson River and Chesapeake Bay von Bertalanffy parameters (Vic Crecco, pers comm). Indices-at-age were then determined by apportioning the spring indices (from Table 2.10) by the percentage of fish in each age.

| Spring |  |  |  |  |  |  |  |  |  |  |  |  |

Table 2.24. Summer flounder indices-at-age, 1984-2006.
Year and season specific age keys obtained from the NMFS spring and fall surveys were used to convert LISTS length frequencies to ages. Starting in 2000 LISTS ageing data ( 60 cm and over) were added to the age key to supplement the older age groups. Indices-at-age were determined for each season by apportioning the spring and fall overall indices (from Table 2.10 and Table 2.11) by the percentage of fish in each age. The age 0-7+ index is the sum of indices ages 0-9.

| Year | Spring |  |  |  |  |  |  |  |  |  |  |

Table 2.25. Tautog indices-at-age, 1984-2006.
Year and season specific age keys obtained from the LISTS spring and fall surveys were used to convert LISTS length frequencies to ages. Indices-at-age were then determined for each season by apportioning the spring and fall overall indices (from Table 2.10 and Table 2.11) by the percentage of fish in each age, and then summing the spring and fall indices-at-age. The age 1-20+ index is the sum of indices ages $1-20+$. The age 20+ category includes 33 fish ranging from 20 to 30 years of age.

| Age |  |  |  |  |  |  |  |  |  |  |  |

Table 2.26. Weakfish age 0 and age $1+$ indices of abundance, 1984-2006.
Using spring (May, June) and fall (September, October) length data, the geometric mean catch per tow was calculated for three groups of weakfish: fall age-0, spring - all fish age 1 and older ( $1+$ ), and fall - all fish age 1 and older ( $1+$ ). Weakfish less than 30 cm fork length in the fall were defined as age-0.

| Year | Fall |  | Fall |  | Spring (May-June) |  |

Table 2.27. Winter flounder indices-at-age, 1984-2006.
The Long Island Sound Trawl Survey April and May catch and age data was used to calculate the geometric mean indices-at-age. An April-May age key was used to convert lengths to ages, and an overall April-May index (the ages 1-13 index in the table) was apportioned by the percentage of fish at age. The 4+ index is the sum of indices ages 4-13 and represents the abundance of winter flounder that are recruited to the fishery. The age-0 indices were obtained from the Estuarine Seine Survey (Job 2 Part 2).

Note: 1984: April = 0 tows, May = 13 tows, and 19 tows in June used to increase sample size; 1985: April = 0 tows, May = 41 tows; 1986-1991: April = 40 tows, May $=40$ tows; 1992: April $=0$ tows, May $=40 ; 1993-1995$ : April $=40$ tows, May $=40$ tows; 1996: April $=17$ tows, May $=63$ tows; 1997-2004: April $=40$ tows and May $=40$ tows; 2005: April $=35$ tows, May $=45$ tows; 2006: April $=0$, and May $=40$ tows.

Table 2.29. American shad length frequencies, spring and fall, 2 cm intervals, 1989-2006.
From 1989-1990, lengths were recorded from the first three tows of each day; since 1991, lengths have been recorded from every tow.

Table 2.33. Blueback herring length frequencies, spring and fall, $1 \mathbf{c m}$ intervals, 1989-2006.
From 1989-1990, lengths were recorded from the first three tows of each day; since 1991, lengths have been recorded from every tow.

Table 2.38. Hickory shad length frequencies, spring and fall, 1 cm intervals, 1991-2006.
Hickory shad were measured from every tow, with the exception of one fish in each of fall 1996, fall 1997, and fall 1998.

| length | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 2.39. Long-finned squid length frequencies, spring and fall, 2 cm intervals (midpoint given), 1986-1990, 1992-2006.
Length frequencies of squid taken from the first three tows of each day.

Job 2 Page 129

Table 2.40. Scup spring length frequencies, 1 cm intervals, 1984-2006.
Lengths were recorded from every tow.

Table 2.42. Striped bass spring length frequencies, 2 cm intervals (midpoint given), 1984-2006.
All striped bass taken in the Survey were measured, with the exception of one fish taken in 1984, one in 1988, and two in 1990.

Table 2.52. Winter skate length frequencies, spring, 1995-2006.
Winter skate were scheduled to be measured from every tow. However, the following numbers of skate were not measured: 4 in 1995, 10 in 1996, and 2 in 1997.

TABLES 2.53-2.60 NARROWS

Table 2.53. Number of additional samples (non-standard LISTS) taken by year and month, 1999-2006.
These additional samples were taken west of Norwalk in a section of the Sound referred to as 'The Narrows' to document species composition and abundance. Precipitated by the lobster mortality events noted in 1999, samples were initially collected ad hoc. In May and June 2000, 10 sites per month were selected. From September 2000 through 2004, six sites were selected for each month that LISTS was conducted. During 2005, sampling was reduced to three sites for each month of LISTS sampling.

| Year |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 2.58. Indices of abundance for selected species in the Narrows, 2000-2006.
The geometric mean count per tow was calculated for 38 finfish and 2 invertebrates. April-June data were used for the Spring indices, September-October data for the Fall (in 2003, there was no October sampling). A time series mean indicates the seasonal index that provides the better estimate of relative abundance in LISTS (Simpson et al. 1991. For American lobster and long-finned squid, both spring and fall indices provide good estimates of abundance.

Job 2 Page 148

Table 2.59. Biomass indices of abundance for selected finfish species in the Narrows, 2000-2006.
The geometric mean weight (kg) per tow was calculated for 38 finfish. April-June data were used for the Spring indices, September-October data for the Fall.

| Species | Spring |  |  |  |  |  |  |

FIGURES 2.1-2.13

Job 2 Page 151

Figure 2.1. Trawl Survey site grid. Each sampling site is $1 \times 2 \mathrm{nmi}$ (nautical miles). A four-digit number identifies the site: the first two digits are the row numbers (corresponding to minutes of latitude) and the last two digits are the column numbers (corresponding to two nautical miles in length on the longitudinal axis). Examples: site 1428 near Guilford and 0028 near Mattituck. (Note: The sites in column 16 are approximately $2 x 1$ nmi. The grid was drawn on the Eastern and Western Long Island Sound 80,000:1 nautical charts, which overlap by the area in column 16.)

Figure 2.2. May 2006 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Narrows sites sampled in western LIS are denoted as green dots. Samples that were collected from a different site than originally selected are noted in table below map.

Job 2 Page 153

Figure 2.3. June 2006 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Narrows sites sampled in western LIS are denoted as green dots. Samples that were collected from a different site than originally selected are noted in table below map.

June 2006 samples that were collected from a different site than originally selected:

| Sample | Site <br> sampled | sampled <br> strata | site selected | selected <br> strata | \# Attempts <br> before <br> moving |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| SP20ason moved |  |  |  |  |  |  |
| SP2006065 | 0223 | M4 | 0023 | M4 | 0 | wrong coordinates in database and area is full of pot gear |
|  | 0522 | M4 | 0320 | M4 | 1 | POTS entangled on doors after 5 minutes (looks like pot sets are N-S) |

Job 2 Page 154

Figure 2.4. September 2006 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Narrows sites sampled in western LIS are denoted as green dots. Samples that were collected from a different site than originally selected are noted in table below map.

Figure 2.5. Number of finfish species observed annually, 1984-2006.

Figure 2.6. Plots of abundance indices for: black sea bass, bluefish (total, age 0, and ages $1+$ ), butterfish, cunner, and dogfish (smooth and spiny).

Legend: $\square=$ count $/$ tow; $\triangle=\mathrm{kg} /$ tow; ---- $=$ mean count $/$ tow

Figure 2.7. Plots of abundance indices for: flounders (fourspot, summer, windowpane, winter, and winter ages $4+$ ) and hakes (red, silver, and spotted).

Legend: $\square=$ count $/$ tow; $\triangle=\mathrm{kg} /$ tow; ---- $=$ mean count $/$ tow

Figure 2.8. Plots of abundance indices for: herrings (alewife, Atlantic, and blueback), hogchoker, Northern kingfish, Spanish mackerel, Atlantic menhaden, and moonfish.

Legend: $\square=$ count $/$ tow; $\triangle=\mathrm{kg} /$ tow; ---- $=$ mean count $/$ tow

Figure 2.9. Plots of abundance indices for: ocean pout, fourbeard rockling, rough scad, longhorn sculpin, and scup (all ages, age 0, and ages 2+).

Legend: $\square=$ count / tow; $\triangle=\mathrm{kg} /$ tow; ---- = mean count $/$ tow

Figure 2.10. Plots of abundance indices for: sea raven, searobins (striped and northern), shad (American and hickory), skates (little and winter), and spot.

Legend: $\square=$ count $/$ tow; $\triangle=\mathrm{kg} / \mathrm{tow} ;----=$ mean count $/$ tow

Figure 2.11. Plots of abundance indices for: striped bass, Atlantic sturgeon, tautog, and weakfish (all ages, age 0 , and ages $1+$ ).

Legend: $\square=$ count / tow; $\triangle=\mathrm{kg} /$ tow; ---- = mean count $/$ tow

Figure 2.12. Plots of abundance and biomass indices for: crabs (lady, horseshoe, rock, and spider), American lobster, and long-finned squid.

$$

Figure 2.13. Plots of spring and fall biomass indices for LISTS vs. Narrows: blue crab, American lobster, rock crab, and spider crab.

## APPENDICES

Appendix 2.1. List of finfish species identified by A Study of Marine Recreational Fisheries in Connecticut (F54R) programs. LISTS has collected ninety-six species from 1984-2006.
This appendix contains a list of 118 species identified (Bold type indicates new species) from all sampling programs conducted since 1984. Species are listed alphabetically by common name (AFS 1991). Sampling program abbreviations are as follows: ESS = Estuarine Seine Survey; IS = Inshore Survey of Juvenile Winter Flounder; LISTS = Long Island Sound Trawl Survey; SNFH = A Study of Nearshore Finfish Habitat. Gear codes are as follows: BT = beam trawl; OT = otter trawl; PN = plankton net; $S=$ seine .

| Common Name | Scientific Name | Sampling Program | Gear |
| :---: | :---: | :---: | :---: |
| anchovy, bay | Anchoa mitchilli | ESS; IS; LISTS | BT; OT; S |
| anchovy, striped | Anchoa hepsetus | LISTS | OT |
| banded rudderfish | Seriola zonata | LISTS | OT |
| bass, calico | Pomoxis sp. | SNFH | PN |
| bass, striped | Morone saxatilis | LISTS | OT |
| bigeye | Priacanthus arenatus | LISTS | OT |
| bigeye, short | Pristigenys alta | LISTS | OT |
| black sea bass | Centropristes striata | ESS; IS; LISTS | BT; OT; S |
| bluefish | Pomatomus saltatrix | ESS; LISTS | OT; S |
| bonito, Atlantic | Sarda sarda | LISTS | OT |
| burrfish, striped | Chilomycterus schoepfi | ESS | S |
| butterfish | Peprilus triacanthus | ESS; IS; LISTS | BT; OT; S |
| cod, Atlantic | Gadus morhua | LISTS | OT |
| cornetfish, bluespotted | Fistularia tabacaria | IS | BT |
| cornetfish, red | Fistularia petimba | IS; LISTS | BT; OT |
| croaker, Atlantic | Micropogonias undulatus | LISTS | OT |
| cunner | Tautogolabrus adspersus | ESS; IS; LISTS | BT; OT; S |
| cusk-eel, fawn | Lepophidium profundorum | LISTS | OT |
| cusk-eel, striped | Ophidion marginatum | LISTS | OT |
| dogfish, smooth | Mustelus canis | ESS; LISTS | OT; S |
| dogfish, spiny | Squalus acanthius | LISTS | OT |
| eel, American | Anguilla rostrata | ESS; IS; LISTS; SNFH | BT; OT; PN; S |
| eel, conger | Conger oceanicus | LISTS | OT |
| filefish, orange | Aluterus schoepfi | LISTS | OT |
| filefish, planehead | Monacanthus hispidus | LISTS | OT |
| flounder, American plaice | Hippoglossoides platessoides | LISTS | OT |
| flounder, fourspot | Paralichthys oblongus | IS; LISTS | BT; OT |
| flounder, smallmouth | Etropus microstomus | ESS; IS; LISTS | BT; OT; S |
| flounder, summer | Paralichthys dentatus | ESS; IS; LISTS | BT; OT; S |
| flounder, windowpane | Scophthalmus aquosus | ESS; IS; LISTS | BT; OT; S |
| flounder, winter | Pleuronectes americanus | ESS; IS; LISTS; SNFH | BT; OT; PN; S |
| flounder, yellowtail | Pleuronectes ferrugineus | IS; LISTS | BT; OT |
| glasseye snapper | Priacanthus cruentatus | LISTS | OT |
| goatfish, dwarf | Upeneus parvus | LISTS | OT |
| goatfish, red | Mullus auratus | LISTS | OT |
| goby, code | Gobiosoma robustrum | ESS | S |
| goby, naked | Gobiosoma bosci | ESS; IS,LISTS | BT; OT, S |
| goosefish | Lophius americanus | IS; LISTS | BT; OT |
| grubby | Myoxocephalus aeneus | ESS; IS; LISTS; SNFH | BT; OT; PN; S |

Appendix 2.4. cont. Total number and weight (kg) of finfish and invertebrates caught in LISTS in 2006.
Finfish species are in order of descending count. Invertebrate species are in order of descending weight (nc $=$ not counted). Young-of-year bay and striped anchovy are neither separated by species or quantified; young-of-year Atlantic herring are not quantified. Number of tows (sample size)=120.

## JOB 2 PART 2: ESTUARINE SEINE SURVEY

## OBJECTIVES

1) Provide an annual index of recruitment for winter flounder (Age0, 1+), all finfsh species taken, and all crab species.

The 2006 annual index of recruitment for young-of-year winter flounder ( 0.9 fish/haul) was the lowest ranking out of 19 annual indices, and just $12 \%$ of the series average of 7.7 flounder/haul.

## 2) Provide an annual total count for all finfish taken.

Mean catch of all finfish ( 118 fish/haul) ranked ninth out of 19 annual indices but was below the series average of 136 fish/haul (Figure 2.2). Geometric means were calculated for 22 species commonly captured since the survey began in 1988 (Table 2.1).

## 3) Provide an index for shallow subtidal forage species abundance.

An index of forage abundance was generated using the catch of four of the most common forage species caught: Atlantic silversides, striped killifish, mummichog, and sheepshead minnow. The index for 2006 ( 59 forage fish/haul) was the sixth lowest of the time series, and well below the time series average of 93 forage fish/haul.

## METHODS

Eight sites (Figure 2.1) are sampled with an eight meter ( 25 ft .) bag seine with $6.4 \mathrm{~mm}(0.25$ in.) bar mesh during September 2006. Area swept was standardized to 4.6 M ( 15 ft .), width by means of a taut spreader rope and a 30 meter ( 98 ft .), measured distance, parallel to, or at a $45^{\circ}$ angle to the shoreline, against the current or tide if present. At each site, six seine hauls were taken within two hours before and after low slack tide during daylight hours. Sites in Groton, Waterford, Old Lyme, Clinton, New Haven, Bridgeport and Greenwich have been sampled since 1988. The Milford site was added in 1990.

Finfish and crabs taken in each sample are identified to species or lowest practical taxon (full listing given in Appendix 2.1, 2.2) and counted. One exception is inland silversides, which are not separated from Atlantic silversides because they are rare and difficult to identify. Qualitative counts were used for menhaden when abundant ( $\mathrm{A}=1000$ ) to minimize discard mortality. Winter flounder are measured to total length (mm), and classified as young-ofyear (YOY) if less than 12 cm and age $1+$ if 14 cm or larger. The age of flounder near this size was verified in 1990-1992 by examination of the sagittal otolith. Physical data recorded at each seine location included water temperature and salinity at one-meter depth. The geometric, or retransformed natural log mean catch per standard haul is calculated for catches at each site and collectively for the 22 most abundant species, with separate indices for young-of-year and winter flounder age 1 and older. Confidence intervals ( $95 \%$ ) for each geometric mean are retransformations of the corresponding log intervals. Frequency of
occurrence is given as a percentage of all samples taken each year.

## RESULTS

A total of 48 seine hauls were taken in 2006 at eight sites, yielding a total catch of 5,653 fish of 29 species and 7,991 invertebrates of 13 species. Mean catch of all finfish ( 118 fish/tow) was the ninth highest in the time series (Figure 2.2). This catch is slightly below the longterm mean of 136 fish /tow is attributed to average or below average catches of Atlantic silversides, striped killifish, mummichog and sheepshead minnnow. Geometric means were calculated for 22 species commonly captured since the survey began in 1988 (Table 2.1). The most frequently caught species was Atlantic silversides, which occurred in 100 percent of all samples, followed by striped killifish ( $65 \%$ ), mummichog ( $48 \%$ ), YOY winter flounder ( $46 \%$ ), northern puffer and pipefish ( $29 \%$ ), grubby ( $27 \%$ ), black sea bass ( $23 \%$ ), tautog ( $17 \%$ ) and cunner ( $13 \%$ ). This rank order has changed from the previous years, with a notable decrease in winter flounder and tautog occurrence rate along with an increase in grubby, pipefish, black sea bass and northern puffer occurrence. Tautog abundance and occurrence rate increased significantly in 1998-99, returned to the series average in 2005, and was below the series average in 2006. Previous to 2005, tautog relative abundance had significantly increased to all-time abundance levels in 2002-04 (Figure 2.4). Summer flounder and inshore lizardfish abundance and occurrence were the highest in the 19 year time-series in 2006. Black sea bass abundance and occurrence were the second highest in the 19 year time-series in 2006. Snapper bluefish were above average in abundance in 2006. Grubby, cunner, northern kingfish, northern pipefish, northern puffer and winter flounder (age $1+$ and older) abundance and occurrence was average for the 19 year time-series in 2006. All other species occurred in less than $15 \%$ of all samples, with occurrence rates similar to previous years. Two new species of finfish were captured in 2006, a northern sennet and a web burrfish.

## Relative Abundance of Juvenile Winter Flounder and Tautog

The 2006 index of YOY winter flounder ( 0.9 fish/haul) was the lowest ranking out of 19 annual indices (Table 2.2, Figure 2.3 and 2.7), and just $12 \%$ the series average of 7.7 flounder / haul. Overall, the time series indicates that relatively strong year classes were produced in 1988, 1992, 1994, and 1996 (Figure 2.3).

The 2006 index of YOY tautog ( 0.4 fish/haul) was the eighth lowest ranking out of 19 annual indices (Table 2.1, Figure 2.3 and 2.7), but below the series average of 0.65 tautog / haul. Overall, the time series indicates a significant increasing trend in abundance of young-of-year tautog from 1988 to 2006, even though the 2006 mean was below the longterm average. $(\mathrm{P} \leq 0.01, \mathrm{t}=2.8, \mathrm{df}=18)$, (Table 2.1, Figure 2.3).

## Presence of Other Important Recreational Finfish

Juvenile striped bass first occurred in the survey in 1999 with one individual captured. In 2003 six more YOY stripers were taken (Table 2.4, Figure 2.8). However, no striped bass were captured in 2006. YOY summer flounder have occurred in five years of the 19 year time series (1993, 1994, 1996, 1998 and 2006). The 2006 summer flounder abundance was the highest of the time series. YOY black sea bass first appeared in 1991 and every year since 1997, reaching their highest abundance in 2001, (Figure 2.7). Snapper bluefish have occurred in 14 out of 19 years of the time series, reaching peak abundance in 1999. YOY scup is another recent addition to the seine survey, first occurring in 1999, with the highest relative abundance in the last six years of the time series, a reflection of strong recruitment in recent years (Table 2.4, Figure 2.8). Juvenile tautog have occurred every year in the seine survey except 1989.

## Relative Abundance of Forage Species

Seine survey catches are dominated by forage species, defined here as short-lived, highly fecund species that spend the majority of their life cycle inshore where they are common food for piscivorous fish. An index of forage abundance was generated using the catch of four of the most common forage species caught: Atlantic silversides, striped killifish, mummichog, and sheepshead minnow (Figure 2.5, Figure 2.6). The index for 2006 was the sixth lowest in the 19 year time series. Atlantic silversides were the most abundant, and the only species present at all sites in all samples (Table 2.1). There was a slight decrease in abundance in 2006. An increase in this species' abundance in 2002 through 2005 reversed a two-year decrease from 2000-2001. Mummichog abundance (2.5) was above the longterm average of 2.0 in 2006. Sheepshead minnow was similar to 2005, ranking ninth highest in the 19 year time series in both total catch and percent occurrence. Striped killifish abundance and occurrence decreased in 2006. Striped killifish abundance was the tenth highest in the 19 year time series and slightly below the series mean of 7.8 fish/haul.

Forage fish abundance has generally been increasing since 1997 (Figure 2.5) after a period of lower abundance (decreasing trend) since 1991. In 2006, forage fish abundance dipped below the series mean of 93 fish/haul, with a mean catch of 59 fish per haul. Forage fish abundance is driven numerically by the occurrence of adult Atlantic silverside (Figure 2.6) and more recently striped killifish, the second most abundant forage species. Striped killifish are more suited to marine habitats, than other 'Fundulus' species captured in the estuarine seine survey. Both Atlantic silverside and striped killifish were captured in slightly below average numbers in 2006, suggesting relatively poor year class production $2-3$ years ago, since the survey captures adults more effectively. Mummichog, the third most abundant forage fish (Table 2.3) in the survey, peaked in abundance in 1994 followed by the lowest time series abundance in 1995, appears to be increasing slightly with an above average catch in 2006. Sheepshead minnow the least abundant of the four forage fish species monitored has recently shown elevated abundance in 2002-2006.

## Relative Abundance of Invertebrate Species

A total of 7,991 invertebrates of 13 species were captured in 2006 (Table 2.3), (Appendix 2.2). Seven crab species were present in the seine hauls, along with three shrimp species and two gastropods. Mud snail, Shore shrimp, sand shrimp, hermit crab, green crab and blue crab were the most abundant, and only hermit crabs were present at all sites (Table 2.3).

## MODIFICATIONS

None.

Table 2.2: Mean catch of young-of-year winter flounder at eight sites sampled by seine, 1988-2006.
The $95 \%$ confidence interval, rounded to the nearest whole number, for each geometric mean per haul is given in parentheses. Sites are listed west to east, left to right.

| Year | Greenwich | Bridgeport | Milford | New Haven | Clinton | Old Lyme | Waterford | Groton | All Sites |

## LIST OF TABLES

Table 5.1. Area $\left(\mathrm{km}^{2}\right)$ by survey and $1.0 \mathrm{mg} / \mathrm{l}$ dissolved oxygen interval during 2006. Actual start and end dates are listed along with number of stations sampled for each survey. 150

Table 5.2. Area-days exposure by survey and dissolved oxygen interval during 2006. Dates are interpolated values between surveys, yielding the days used in area-day calculation. 150

Table 5.3. Biomass-Area-Day-Depletion (BADD) values by survey and dissolved oxygen interval during 2006. BADD values are calculated as area-days x percent impairment (shown in parentheses) associated with each dissolved oxygen interval. Impairment based on demersal finfish biomass response. BADD values were recalculated using area-days calculated in the 3$3.5 \mathrm{mg} / \mathrm{L}$ interval as DO’s above $3.5 \mathrm{mg} / \mathrm{l}$ are not limiting. Previously these results used one-half the area-days calculated for the interval $3-3.99 \mathrm{mg} / \mathrm{L}$.

## LIST OF FIGURES

Figure 5.1. Timing and duration of hypoxia in Long Island Sound from 1991 through 2006. In 2006 hypoxia developed on or about July 4 and persisted 57 days, ending on or about August 29, 2006.

Figure 5.2. a) Maximum area $\left(\mathrm{km}^{2}\right)$ less than $1.0 \mathrm{mg} / \mathrm{l}$ DO, b)maximum area $\left(\mathrm{km}^{2}\right)$ less than 3.5 $\mathrm{mg} / \mathrm{l}$ DO, c) duration (days) of hypoxia ( $\mathrm{DO}<3.5 \mathrm{mg} / \mathrm{l}$ ), d) biomass area-day depletion (BADD) index of temporary habitat loss to demersal finfish associated with hypoxia conditions each year.

Figure 5.3. Surface and bottom salinity calculated from six axial water quality stations (B3, D3, F3, H6, I2 and M3) for the period between 1991 and 2006. Monthly (survey) means are plotted against the 1991-2006 time series mean.

Figure 5.4. Surface and bottom temperature calculated from six axial water quality stations (B3, D3, F3, H6, I2 and M3) for the period between 1991 and 2006. Monthly (survey) means are plotted against the 1991-2006 time series mean.

## JOB 5: COOPERATIVE INTERAGENCY RESOURCE MONITORING

## GOAL

To provide long-term monitoring of physical, chemical and biological indicators of environmental conditions in order to evaluate the effects of non-fishing activities on the health and abundance of valued recreational species.

## OBJECTIVES

1) Provide monthly monitoring of water quality parameters important in the development of summer hypoxia in Long Island Sound including temperature, salinity, and dissolved oxygen, at eighteen fixed axial and lateral stations throughout Long Island Sound.
2) Provide estimates of the area and duration of summer hypoxia (low oxygen) in Long Island Sound based on sampling at an additional 30 fixed sites semi-monthly between June and September.

## INTRODUCTION

## Long Island Sound, Living Resources and Hypoxia

Long Island Sound (the Sound) is a semi-enclosed estuary that encompasses $3,370 \mathrm{~km}^{2}$ (337,000 ha) including embayments (Wolfe et al., 1991) and receives runoff from a $41,400 \mathrm{~km}^{2}$ drainage basin that includes Long Island, New York and much of New England to the Canadian border. More than 7 million people live within the state of Connecticut and New York counties bordering the Sound (LISS 1990). The Sound has typically acted as the receiving body of domestic, agricultural and industrial waste generated within the region.

Excessive nutrient inputs (most notably nitrogen) from atmospheric deposition, runoff and sewage discharges as well as natural sources results in a high rate of primary (phytoplankton) production within the Sound. Summer warming of surface water results in a temperature and density stratification within the water column, known as the pycnocline. As phytoplankton blooms die off and decompose, oxygen in bottom waters is used up, often resulting in hypoxia (low dissolved oxygen, $\mathrm{DO}<=3.5 \mathrm{mg} / \mathrm{l}$ ) and in some cases, anoxia ( $\mathrm{DO}<0.2$ $\mathrm{mg} / \mathrm{l}$ ). These periodic hypoxic events generally develop by early July and may persist until late September.

Simpson et al, (1995) identified low oxygen tolerance thresholds for 16 individual species of finfish and lobster, and six aggregate species indices. For the most sensitive species (scup, striped sea robin) dissolved oxygen becomes limiting at over $4.0 \mathrm{mg} / \mathrm{l}$, whereas more highly tolerant species (Atlantic herring and butterfish) did not decline in abundance until oxygen levels were below $2.0 \mathrm{mg} / \mathrm{l}$. Both demersal species biomass and demersal species richness begin to decline when dissolved oxygen levels fall below about $3.5 \mathrm{mg} / \mathrm{l}$. No finfish or macroinvertebrates were observed when dissolved oxygen fell below $1.0 \mathrm{mg} / \mathrm{l}$.

An index of habitat impairment (Biomass Area-Day Depletion, BADD) was developed based on the percent reduction in demersal finfish biomass associated with each $1 \mathrm{mg} / \mathrm{l}$ interval below $3.5 \mathrm{mg} / \mathrm{l}$. In addition to BADD, inter-annual trends in the severity of hypoxia are monitored using duration (weeks where $\mathrm{DO}<3.5 \mathrm{mg} / \mathrm{l}$ ) and maximum areal extent of waters with severe hypoxia ( $\mathrm{DO}<1.0 \mathrm{mg} / \mathrm{l}$ ). Together, these three indices are used to relate dissolved oxygen trends to conditions for living resources in the Sound.

## Water Quality Monitoring Program

In January 1991, Connecticut DEP initiated a water quality and hydrographic survey to provide continuity to a time series begun in 1988 under the National Estuaries Program's, Long Island Sound Study. This survey continues in an expanded form with EPA (and Federal Aid in Sportfish Restoration) support as the Department's "Long Island Sound Ambient Water Quality Monitoring Program."

In the first three years of this study (1991-1993), sampling was conducted cooperatively between Marine Fisheries and Water Management staff to evaluate dissolved oxygen (DO) conditions and coincident fish abundance. With the completion of fishery resource sampling in 1993, emphasis shifted to intensive water quality monitoring under the Bureau of Water Management. In 1994, forty-eight permanent stations were established to monitor summer hypoxia; eighteen of these stations are sampled on a monthly basis year-round. Marine Fisheries staff continue to provide research vessel support and rely on this program to evaluate the effects of hypoxia on living resources through the three indices identified above. In addition, monthly patterns in temperature and salinity have proven useful in understanding both seasonal and interannual trends and in making inferences concerning fishery resources.

## METHODS

## Sampling Design

In 1994, 48 fixed stations were established to monitor hypoxia. Beginning in December 1994, eighteen of these stations were also sampled as part of the monthly water quality monitoring program, an expansion from the previous seven axial station coverage. In 1998 a $49^{\text {th }}$ station (J4) was added in the eastern Sound. Monthly stations were distributed to provide axial coverage over the length of the Sound, including a reference station outside the Sound, southeast of Fishers Island. Transverse stations were located off New Haven, Bridgeport and Norwalk. Summer hypoxia monitoring stations are concentrated in the hypoxia prone western half of the Sound, although Connecticut shoreline coverage extends east of the Connecticut River. The eighteen monthly stations are sampled year round, generally during the first week of the month. Beginning in the end of June, hypoxia monitoring commences and twice monthly hypoxia sampling continues through September. During the summer of 2002 Connecticut DEP modified the summer hypoxia sampling by decreasing the number of stations sampled from 49 down to between 20 and 25 . These changes were made to make better use of the resources available and to better reflect the understanding from eleven years of monitoring. The mid month Hypoxia surveys will be limited to the narrows, western and central basins with a focus on stations that historically have been affected by hypoxic conditions. The number of stations sampled on these surveys will be adjusted according to the severity of the hypoxic event. During years of unusually severe hypoxia additional stations will be monitored to ensure an accurate assessment of the area affected by low dissolved oxygen.

## Sampling Procedures

Water sampling is conducted from the 15.2 m Research Vessel John Dempsey. Conductivity-temperature-depth (CTD) water column profiles are taken with a Sea-Bird model SBE-19 SeaCat Profiler, equipped with dissolved oxygen (YSI model 5739), photosyntheticallyactive radiation (PAR) (Licor spherical underwater model 193SA) and Fluorometer (WET labs WETstar Miniature Fluorometer) sensors. Data are recorded at a rate of twice per second and the instrument is lowered through the water column at a rate of 0.2 m per second. Dissolved oxygen is also measured by Winkler titration as a quality assurance procedure. Nutrients, and chlorophyll a are also measured. See Kaputa and Olsen (2000) for a complete description of the Long Island Sound Water Quality Monitoring Program. Beginning in 2002 CTDEP expanded its monthly monitoring by adding phytopigment analysis (HPLC method) in April of 2002 and Zooplankton analysis in August of 2002. MesoZooplankton samples are collected using a 200micron mesh, 0.5 meter double ring plankton net and MicroZooplankton samples are collected from a multiple depth composite of whole water samples. These changes have been extended and will continue through the end of 2007.

## Area and Duration Estimates

In the initial years of this project (1991-1993) the area affected by hypoxia was estimated using a stratified-random sampling approach where stations were selected at random within five east-west zones, further subdivided by depth at the 18 m contours (Gottschall and Simpson, 1999). Although a fixed station sampling program was adopted in 1994, the method of area calculation remained unchanged. Subsequently, staff from the Bureau of Water Management developed an ArcView based method. This approach is more appropriate for a fixed station design and has been adopted for this report. The historical time series using this new method will be developed and presented in future reports.

To calculate the area affected by hypoxia, the minimum dissolved oxygen and the location of each station sampled during each survey was entered into a Geographic Information System (ArcView) database and plotted. The Spatial Analyst extension in ArcView was used to interpolate DO values between stations using the inverse distance weighted (IDW) method, producing a cell grid of minimum DO values for the Sound. The area within each $1 \mathrm{mg} / \mathrm{l}$ DO interval ( $0-0.99 \mathrm{mg} / \mathrm{l}, 1.0-1.99 \mathrm{mg} / \mathrm{l}$, etc) was estimated by multiplying the number of cells within each DO interval by the area within each cell (approximately 0.1 square km). Area estimates include LIS waters shoreward to the 4.0 m contour, except at the eastern (The Race, Fishers Island, Thames River) and western (Throgs Neck Bridge) boundaries, encompassing a total of 2,723 square km.

The duration of each annual hypoxia event in LIS was estimated using the time series of bottom water dissolved oxygen concentrations at each station. Start and end dates were approximated for each station graphically by determining the intersection of the time series line with the $3.5 \mathrm{mg} / \mathrm{l}$ grid line. The earliest start date and latest end date - regardless of station provided the preliminary start and end date estimates for the year. Data available from the Long Island Sound Trawl Survey (Job 2), other programs and agencies, as well as daily wind and precipitation records were then considered. Such supplementary data improved the date estimates by filling in gaps between sampling events and accounting for substantial wind or storm events that would likely have provided the energy necessary to mix the water column.

## Indices of Habitat Impairment Associated with Hypoxia

An index of habitat impairment (Biomass Area-Day Depletion, BADD) was developed based on the percent reduction in demersal finfish biomass associated with each $1 \mathrm{mg} / \mathrm{l}$ interval below $3.5 \mathrm{mg} / \mathrm{l}$. Based on Simpson et al (1996), demersal finfish biomass is reduced 100\% (total avoidance) in waters with $\mathrm{DO}<1.0 \mathrm{mg} / \mathrm{l}$. From $1.0-1.9 \mathrm{mg} / \mathrm{l}$ biomass is reduced $82 \%$, while a $41 \%$ reduction occurs at $2.0-2.9 \mathrm{mg} / \mathrm{l}$, and a $04 \%$ reduction occurs at $3.0-3.5 \mathrm{mg} / \mathrm{l}$ dissolved oxygen. These rates are applied to the area-days within each DO interval calculated during each survey and summed over the hypoxia season defined here as July 1 - September 10 ( 72 d ). The index is then expressed as a percentage of the available area-days (sample area $2,723 \mathrm{~km}^{2} \times 72$ d, or 196,056 area-days). In addition to BADD, inter-annual trends in the severity of hypoxia are monitored using duration (weeks where $\mathrm{DO}<3.5 \mathrm{mg} / \mathrm{l}$ ) and maximum areal extent of waters with severe hypoxia ( $\mathrm{DO}<1.0 \mathrm{mg} / \mathrm{l}$ ).

## RESULTS AND DISCUSSION

## Hypoxic Area and Duration

During the summer of 2006, seven cruises were conducted, beginning in early June and ending by mid-September. A total of 234 site visits were completed in 2006, with 29 stations affected by hypoxia throughout the season. In 2006, hypoxic conditions were estimated to have begun on 4 July and ended on 29 August, approximately 57 days (Figure 5.1). The peak event occurred in early August. The maximum area with bottom water DO less than $3.5 \mathrm{mg} / \mathrm{L}$ was 896 $\mathrm{km}^{2}$ (Table 5.1). In 2006 the area less than $3.5 \mathrm{mg} / \mathrm{L}$ was larger than during the 2004 and 2005 seasons; however, the duration was the shortest since 2000.

## Habitat Impairment Associated with Hypoxia

During the summer of 2006 an area of $45 \mathrm{~km}^{2}$ was exposed to severe hypoxia ( $<1.0 \mathrm{mg} / \mathrm{l}$ ) (Table 5.1). Such conditions would be expected to completely exclude demersal finfish.

Area-days by DO interval were calculated for each survey (Table 5.2) to produce the biomass-area-day-depletion (BADD) index used to quantify habitat impairment (Table 5.3). The greatest impairment was associated with the $2.0-2.99 \mathrm{mg} / \mathrm{l}$ DO interval due to the wider area of exposure estimated for this interval throughout the summer.

The BADD index was calculated for the 72 day period between June 30 and September 7. The BADD index for 2006 was 7,017 or $3.6 \%$ of the total area-days in the LIS sampling area covered by the Long Island Sound Water Quality Monitoring Program.

## Monthly Salinity and Temperature Trends

Monthly mean surface and bottom water temperature and salinity were calculated from six axial water quality stations (B3, D3, F3, H6, I2 and M3) for the period between 1991 and 2006. Plots of each year against the time series mean illustrate the inter-annual variability in both salinity (Figure 5.2) and temperature (Figure 5.3). In some cases, deviations from the 1991-2006 mean can be associated with fish population events. For example, strong winter flounder recruitment indices observed in 1994 and 1996 (Job 2) are consistent with colder than average late winter water temperatures that are believed to enhance survival of flounder larvae.

Missing stations can affect monthly means. Therefore the plotted values should be regarded
as a qualitative summary of salinity and temperature trends.

## JOB 6: PUBLIC OUTREACH

## GOAL

To increase awareness among anglers and the general public of the information products provided by this project and how this information contributes to state and federal efforts to enhance, restore and protect marine habitat and recreational fish populations.

## OBJECTIVES

1) Increase public awareness that research \& monitoring are essential to good fisheries management and the majority of marine fisheries research \& monitoring activities in Connecticut are funded through excise tax on fishing tackle and motorboat fuels

## SUMMARY

1. A total of 27,822 outdoor and environmental writers, marine anglers and boaters, marina operators, fishing tackle retailers, Fisheries Advisory Council (FAC) members, and members of the general public attended outreach events where the importance of research and monitoring to good fisheries management was incorporated into the program (Table 6.2).
2. These same audiences also learned that good water quality and proper pollution prevention (non-fishing impacts) are essential to good fisheries habitat management.
3. Total attendance at several speaking engagements with sportsmen clubs and other recreational clubs was 413 (Table 6.2). The audience was encouraged to become actively involved in the fishery management process by attending public hearings and FAC meetings. Notices of public hearings were sent to hundreds of tackle shops and various media outlets.
4. The message that the majority of marine finfish research and monitoring are funded through excise taxes on fishing and motorboat fuels was emphasized at major department outreach events (Table 6.2).

## INTRODUCTION

Public outreach was formally incorporated into this project in 1997 (segment 17). An outreach plan was developed by project staff working closely with US Fish and Wildlife Service personnel. Six target audiences were identified in priority order (Table 6.1) in the outreach plan. This report summarizes F54R outreach activities conducted from March 2006 to February 2007 (segment 26).

## RESULTS AND DISCUSSION

## Outdoor and Environmental Writers

## Table 6.1

Priority Audiences for Outreach Activities

1. Outdoor/environmental writers
2. Marine anglers
3. Marine boaters and marina operators
4. Fishing tackle retailers
5. Fisheries Advisory Council (to CT DEP)
6. General public

DEP press releases, project summaries and full annual reports were mailed out to several outdoor writers and members of the CT Outdoor Recreation Coalition (CORC). Project staff were also interviewed concerning F54R activities in person, at public and regulatory hearings, and over the telephone by writers and reporters for the news media. One article written by Connecticut reporters describing Long Island Sound and Lobster health was published in the Connecticut Post in April of 2006. (see Appendix 6.1).

## Marine Anglers and Marine Boaters

Project personnel organized and assisted in DEP, Marine and Inland Fisheries Division displays at two statewide fishing shows. The shows were sponsored by CMTA, Dodge Trucks, Channel 3 and Connecticut Outdoor Recreation Coalition and were held in January and February 2007 at the Connecticut Convention Center. These shows attracted 26,542 anglers, non-anglers, boaters, tackle retailers, legislators and general outdoor recreation enthusiasts. The theme for this show was "No Child Left Inside" and Trophy Fish Close to Home". F54R activities were highlighted at this shows in displays entitled "Trophy Fish Award Program" and "Marine Regulations, (A fisheries management explanation)". Audiences learned the importance of research and monitoring which are funded through excise taxes on fishing tackle and motorboat fuels. Colorful posters and pictures, brief project specific text and taxidermy reproductions helped draw attention to marine species monitored under F54R programs and solicit questions and discussion of those programs.

Several outreach displays were developed by project staff and mounted in the lobby and hallways at the Marine Fisheries Headquarters in Ferry Point State Park. These displays highlighted unique characteristics of Long Island Sound, public access, species identification, the trophy fish award program, and gave a brief description of current F54R programs designed to protect the Sound's resources. These fisheries displays can easily be viewed by anglers, boaters, and their families at this popular fishing and picnic area.

## Fishing Tackle Retailers

Fishing tackle retailers provide an important avenue for communication between the department and anglers. A complete list of fishing tackle retailers is maintained and updated yearly. Timely DEP press releases, species fact sheets, and Connecticut angler guides are mailed to tackle retailers to keep them informed. Correspondence between the marine fisheries office staff and retailers are ongoing.

## Fisheries Advisory Council

The Fisheries Advisory Council, which represents a cross section of Connecticut residents with interests in fisheries issues, met quarterly to discuss statewide fisheries issues. After each meeting most Council members report Council discussions back to the fishing and environmental groups they represent. Council members also discussed monitoring and funding issues at meetings with state legislators. Several Council members visited Marine Fisheries displays at the Northeast Fishing and Hunting Expo, CMTA Boating and Fishing Show and other activities the Fisheries Division held during National Fishing Week. 'A Study of Marine Recreational Fisheries in Connecticut' was mailed to Fishery Advisory Council members to keep them informed.

## General Public

Marine Headquarters is open daily Mon-Fri. attracting hundreds to the public outreach displays at the office. Display topics included all F54R projects. Activities funded under other Federal Aid in Sport Fish Restoration projects were also highlighted; including Connecticut Pumpout Stations and Waste Reception Facilities (V-4), Motorboat Access Renovation and Development (F60D), Motorboat Access Area Operation and Maintenance (F70D), and Habitat Conservation and Enhancement (F61T).

Sport Fish Restoration projects were also highlighted in a one-day environmental science festival "Marine Science Day" program held in May at the UCONN Avery Point Campus in Groton CT. Presentations titled "Marine Fisheries Management / Sportfish Restoration and Marine Resources" were provided to students. This event highlighted the importance of coastal resources and all facets of marine resource resource protection. Approximately 325 students attended the Marine Science Day at the University of Connecticut.

Finally, project staff lead numerous workshops and speaking engagements throughout the state, as well as informational tours and talks at the Marine Fisheries Office (Table 6.2). These talks and tours reached all target audiences, especially the business community, teachers and students. Audiences learned how to become active participants in the management process, through public hearings and FAC Meetings.

## APPENDIX 6.1

Warming Sound has lobsters in a pinch
By John Nickerson
Staff Writer

April 9, 2006
BRIDGEPORT -- Rising water temperatures could be to blame for the steep decline in lobsters and other cold-water species once found in abundance in Long Island Sound. According to researchers gathered yesterday in Bridgeport for the $16^{\text {th }}$ annual Long Island Sound Summit, the Sound is experiencing a dramatic change in the types of wildlife that reside there. Trawling surveys over the past 20 years show the number of cold-water species such as winter flounder, American lobster, cunner and spiny dogfish are declining while warm-water species such as bluefish, menhaden, hickory shad, black sea bass and summer flounder are turning up far more regularly.

For example, Connecticut landings of the American lobster, which peaked at 3.7 million pounds in 1998, was down to about 710,000 pounds last year, according to the state Department of Environmental Protection. One significant reason for that decline is probably rising water temperatures, said Lawrence Swanson of Stony Brook University's Marine Sciences Research Center. Swanson said that from 1991 to 2002, water temperature at the bottom of the Sound increased by about 1 degree and put the Sound's lobster at the knife's edge of its survivable habitat.

Robert Whitlatch, a marine science professor at the University of Connecticut, said climate change not only affects traditional denizens of the Sound, it also opens the door to a host of invasive species. From the 1940s to 1970 -- a time of little temperature change -- few if any non-native species gained a foothold in local waters, Whitlatch said. But since the mid-1970s, when water temperatures began to climb, four types of soft-bodied tunicates -- commonly called sea squirts - have invaded the Sound.

The most recent sea squirt, Didemnum, which grows at unrivaled speeds into thick pancake batter-like globs, has covered much of the sea floor in the eastern part of the Sound. "It is marching down the Sound," Witlatch said. "A few degrees
difference in mean winter temperatures correlates with a large reversal in the relative dominances of resident and invader species."

Wesleyan University professor Johon Varekamp said water levels in the Sound are climbing three times faster than 1,500 years ago. After years of collecting core samples of mud from all over the Sound, Varekamp said he has determined that at about the year 500, the sea level was increasing by nearly a millimeter per year. In about 1850, the sea level grew by about 1.7 millimeters per year, and in the 1900s, it has increased to 3 millimeters per year. As an example of what sea levels have done, Varekamp compared pictures of Scotts Cove in Darien from 1965 to now, showing marsh areas that are now covered with water. Varekamp said the reason for the change is global warming. Nitrogen in the Sound, which robs the water of oxygen and causes fish kills, has risen in seemingly exact correlation with the population and the amount of sewage dumped in the water, Varekamp said. "We are looking for the devil and we have found ourselves," he said.

DEP Commissioner Gina McCarthy said the Sound faces many challenges, not the least of which is sprawl, which is "eating up" the Sound's coast line. "We have to continue to love Long Island Sound, but we can't love it todeath," McCarthy said, Probably the greatest threat to the ecology of the Sound is climate change, she said. "There is more evidence that climate change is real than there is proof that cigarette smoking causes cancer," McCarthy said. "Something is happening, and frankly, we are the reason something is happening here." Copyright (c) 2006, Southern Connecticut Newspapers, Inc.
