## A STUDY OF MARINE RECREATIONAL FISHERIES IN CONNECTICUT

Federal Aid in Sport Fish Restoration
F15AF00222 (F-54-R-35)
Annual Performance Report
March 1, 2015 - February 29, 2016

## Cover Photos: David (Dave) Simpson during his time spent on the water with the Long Island Sound Trawl Survey over the past 36+ years and how he plans to spend his upcoming retirement (FISHING!)

David G. Simpson, of the Marine Fisheries Division, is featured on the cover of this year's report to honor his significant contributions to the project and to fishery management in Connecticut. After a 36+ year career as a marine fisheries biologist with the department, Dave set his retirement for September 1, 2016. Dave began working for the "Marine Region" as a seasonal resource assistant for $\$ 4.18$ per hour back in 1980 when the office was located on the grounds of Harkness State Park in Waterford. Having been a mate and captain of the Blackhawk party fishing boat in the late 1970's, Dave was the obvious choice to captain the research vessel James P. Galligan II in the inaugural year (1984) of the "F54" Long Island Sound Trawl Survey. Dave subsequently became PI for the trawl survey and eventually became supervising fisheries biologist overseeing the survey PI as well as others. Dave was also instrumental in the design, construction and delivery of the John Dempsey, the division's present research vessel.

As his career developed, Dave served on many interstate committees including the Summer Flounder, Scup and Black Sea Bass Technical Committee, the ASFMC Management and Science Committee, NEAMAP Management Board and a five-year or so stretch as Connecticut's designee to the New England Fishery Management Council. Dave became director of the Marine Fisheries Division in 2008 and set about making his mark on the Division and fishing in Connecticut. Not afraid to depart from convention, Dave applied creativity and innovation in parleying Connecticut's unutilized commercial striped bass quota into the Bonus Striped Bass Fishing Program, which was initially conceived to provide enhanced recreational striped bass fishing opportunity for urban, youth and shore anglers. He similarly instituted the Enhanced Opportunity Shore Fishing Program, giving shore-bound anglers greater chance for fishing success through a reduced size limit for scup and summer flounder at certain designated shore fishing sites.

Dave's steady and unflappable manner and his ability to make well-reasoned decisions and find practical solutions to problems have truly been an asset to the trawl survey and to the Marine Fisheries Division. We sincerely wish him well in his retirement, and hope that he leaves at least a few fish in the Sound for continued success of the LIS Trawl Survey.

Annual Performance Report

## Project Title: A Study of Marine Recreational Fisheries in Connecticut

Period Covered: March 1, 2015 - February 29, 2016

## Job Title

Job 1: Marine Angler Survey
Job 2. Volunteer Angler Survey
Job 3. Enhanced Shore Fishing
Job 4. Tackle Shop Co-Op Survey
Job 5. Long Island Sound Trawl Survey
Job 6. Studies in Conservation Engineering
Job 7. Alosine Survey
Job 8. Estuarine Seine Survey
Job 9. Volunteer Estuarine Fisheries Database
Job 10. Cooperative Interagency Resource Monitoring
Job 11. Public Outreach
Job 12. Marine Fisheries GIS

## Approved by:

David G. Simpson, Director
Date: August 15, 2016

Marine Fisheries Division

## EXECUTIVE SUMMARY

Project: A Study of Marine Recreational Fisheries in Connecticut
Federal Aid Project: F54R-35 (Federal Aid in Sport Fish Restoration)
Annual Progress Report: March 1, 2015 - February 29, 2016

## Purpose of the Project

The Long Island Sound (LIS) drainage basin encompasses more than 16,000 square miles and a population of 8.4 million people. Coastal communities account for $87 \%$ of the population, with an average density of 3,961 persons/sq mi compared to 558 per square mile basin-wide and 64 per sq mi nationally, and so constitutes one of the most densely populated areas in the nation.

This concentrated population has placed a significant burden on the Sound. Nevertheless, Long Island Sound and its tributaries in Connecticut support a wide diversity of marine life including many recreationally valuable species. Recreational fisheries for bluefish, winter flounder, scup, tautog, striped bass, summer flounder, and other species attract approximately 140,000 licensed anglers making on average 1.5 million fishing trips to the Connecticut coastline each year. The total value of the recreational fishery in both New York and Connecticut waters of LIS currently exceeds $\$ 100$ million annually, while the commercial fishery contributes an additional \$80 million each year.

Regionally, the recreational and commercial fisheries for these species have historically been intensive and in several cases overfishing led to depleted stock conditions and lost fishing opportunity during the 1980's and 1990's. Striped bass and summer flounder were reduced to record low levels in the mid to late 1980's whereas scup, winter flounder and tautog abundance reached minimum levels in the mid-1990's. Alarmed by the decline in these resources, fishery managers imposed new restrictions on harvest. Striped bass harvests were cut drastically, initially by the "producer states" of Maryland, then Virginia, and later by the coastal states under the Atlantic Striped Bass Conservation Act of 1984 resulting in the first fishery management plan among Atlantic coastal states with compulsory compliance provisions. Following striped bass, Amendment 2 to the Summer Flounder Fishery Management Plan (FMP) adopted quota based management restricting both recreational and commercial harvest coast-wide beginning in 1993. Scup, tautog and winter flounder FMPS's followed suit with very restrictive harvest limits. Aggressive fishery management has resulted in dramatic stock recovery for striped bass, summer flounder and scup, while helping to mitigate declining trends in tautog abundance. Winter flounder remain seriously depleted as a result of a combination of factors, likely including overfishing, unfavorably mild winter temperatures and increased predation.

The stock assessments for these species are revised and updated routinely to support continued management. These assessments require up-to-date basic population monitoring of age structure, growth and age at maturity. They also require detailed catch and effort statistics, estimates of fishery discarding and discard mortality rates as well as fishery independent measures of abundance, exploitation and size composition. In addition, as stocks of principal inshore predators are restored, questions have arisen concerning the status of the forage base and its ability to support growing predator populations. Finally, evaluating water quality management efforts to increase average summer dissolved oxygen levels in the western Sound through nitrogen reduction programs require oxygen monitoring and direct periodic evaluation of finfish responses.

This project is designed to address all of these issues by monitoring trends in abundance of all common marine finfish, including age and growth of selected sportfish, and by estimating harvest rates and size composition for a variety of important recreational species. Jobs 1-8 are designed to provide the components of stock assessments described above based on the resources and the recreational and commercial fisheries occurring in Long Island Sound. Catch and size composition of the fishery (Jobs 1-4) and fishery independent measures of abundance and size composition (Jobs $5-8$ ) are vital to understanding how regional fishery management plans are likely to affect local stocks and the fishery they support. Each of these jobs also provides the basis for developing state specific strategies for compliance with fishery management plans where such latitude is permitted.

Evaluating the effects of non-fishing human activities on the health and abundance of valued recreational species is critically needed as part of a comprehensive management strategy being implemented for these resources by Long Island Sound Study member agencies (CTDEEP, NYDEC, NYCDEP, USEPA) and the Marine Fisheries Division. As a consequence of Connecticut's urbanized shoreline, LIS waters are subject to multiple impacts from human activities. Continued expansion of these activities has led to conflicts between different users and clashes between human activities and the sustained productivity of this ecosystem. In addition to human alterations, the LIS estuary experiences physical challenges to its productivity due to storms, sea-level rise and other climate effects. Job 10 provides trends in area, duration and intensity of hypoxia, the most significant water quality problem facing the Sound today.

Since its formation in the early 1970s, the Department has placed a high priority on environmental literacy for all of the state's citizens. Job 11 provides for public outreach to communicate with anglers and other interested citizens concerning the benefits of this project in particular and of the Federal Aid in Sportfish Restoration program in general. Several citizens’ groups have formed in response to educational programs and/or to address local environmental issues. These groups have spent thousands of volunteer hours gathering species-specific fisheries abundance data and accompanying water quality information. This piecemeal approach has met local short-term goals but does not lend itself to meeting larger goals. Collectively these data could form a robust context for evaluating region-wide environmental impacts due to human activities, harvest removals, and long-term physical habitat change. Job 9 provides a mechanism for collating these data in a comprehensive manner. Additionally, the Job provides a means for a second critical component of cross-program standardization, or quality assurance, which would be required to join the different datasets. This project addresses these shortcomings by establishing a flexible data framework where historical datasets can be collated, standardized, and accessed.

In recent years, there has been an increased need for staff to use geospatial technology to map and analyze marine environmental or fisheries related information. Project staff have also experienced an increasing number of requests to provide geospatial data to others (intra-agency, inter-agency, private organizations, academic institutions, and concerned members of the public). Job 12 is designed to support this need for geospatial datasets, data layers, analyses and products.

## Job 1: Marine Angler Survey

Goal: To enhance the fisheries management process by providing supplemental catch, effort and size composition data for several important recreational finfish species through a voluntary catch card survey program targeting private boat anglers from specific eastern and western Connecticut boat launches.

## Key Findings:

- DEEP staff completed 788 interviews and distributed 947 catch cards to boat based anglers at launch sites equally distributed in eastern and western portions of the state ( 441 interviews, 478 cards east of CT River; 347 interviews, 469 cards west of New Haven).
- A total of 168 cards were returned (18\%) with 510 anglers reporting their fishing trip activities. Of the 510 anglers, 395 (77\%) caught at least one fish. A total of 1,229 (43\%) fish were kept and 1,655 (57\%) fish were released, including 19 finfish species or species groups.
- There were a total of 2,876 fish reported caught. 1,244 (43\%) were harvested and 1,655 (57\%) were released at sea.
- A total of 1,376 fish reported caught at the eastern locations. 607 (44\%) were harvested and 769 (56\%) were released at sea.
- Another 1,508 fish reported caught at the western locations. 622 (41\%) were harvested and 886 (59\%) were released at sea.
- There were 19 different species of fish reported caught. The most commonly caught species were scup, summer flounder, tautog, black sea bass and striped bass which make up $82 \%$ of the total catch.
- Anglers measured a total of 2,876 fish. The top three species measured scup (609 lengths), summer flounder ( 575 lengths), tautog (438 lengths) and black sea bass (412 lengths).

## Conclusions:

- Coastwide fishery management plans are resulting in increases in several fish populations and good catches of many primary recreational species throughout long island sound.

## Recommendations:

- Continue to obtain catch and harvest information and angler participation rates in order to monitor the status of the recreational fishery. Sampling levels will be curtailed in 2016 due to the Division's increased involvement in the Marine Recreational Information Program (MRIP).

## Job 2: Volunteer Angler Survey

Goal: To enhance the fisheries management process by providing supplemental catch, effort and size composition data for several important recreational finfish species through a voluntary logbook program.

## Key Findings:

- A total of 33 anglers participated in the survey and made 762 trips in 2015. Volunteers made 460 trips with a private boat and 28 from a party/charter boat. Additionally, 220 fishing trips were recorded from shore sites under regular regulations and 54 from enhanced shore sites (see Job 3).
- Volunteer anglers caught a total of 8,216 finfish. A total of 2,121 were harvested (26\%) and 6,095 were released (74\%).
- There were 20 different species of fish reported caught. The most commonly caught species (in rank order) were scup, summer flounder, black sea bass, both species of searobin, bluefish, striped bass, menhaden, and tautog, which make up $88 \%$ of the total catch.
- Anglers measured a total of 7,795 fish. Seven principal recreational species measured were scup (1,768 lengths), summer flounder (1,682 lengths), black sea bass (1,547 lengths), striped bass ( 593 lengths), bluefish (618 lengths), tautog ( 373 lengths) and winter flounder ( 6 lengths).
- Collecting length measurements on released fish provides valuable data not available through the Marine Recreational Information Program except for the party boat mode.

## Conclusions:

- Volunteer anglers provide a tremendous amount of data on the size and catch composition of popular recreational species in Connecticut, supplying several stock assessments with scarce length information on released fish.

## Recommendations:

- Maintain the Volunteer Angler Survey as an effective means of characterizing angler behavior, especially in collecting length data on released fish that are not available from the Marine Recreational Information Program.

## Job 3: Enhanced Shore Fishing

Goal: To maintain and improve the shore fishing experience, opportunity and quality of access to public trust marine fisheries resources in Connecticut, especially in urban areas, while maintaining marine fish conservation objectives.

## Key Findings:

- Creel survey agents spent a total of 1,054 hours at 31 enhanced shore fishing sites between Stonington and Norwalk CT from May through December 2015. A total of 219 assignments included 1,462 sites sampled in five zones.
- Creel agents observed 2,075 angler hours of fishing. The top three sites with the most observed fishing were CT DEEP Marine Headquarters (Old Lyme) which averaged 6.0 anglers per hour, South Benson (Fairfield) with 3.8 anglers per hour and the South Cove Causeway (Old Saybrook) averaging 3.1 anglers per hour.
- A total of 1,958 anglers were interviewed and 1,736 catch cards were distributed. Of these, 682 (39\%) cards were returned. Catch data was collected from both the field interview and the returned catch cards.
- 1,434 fish were reported caught in the catch cards, of which 780 fish (54\%) were released and 654 fish (46\%) were reported kept.
- There were a total of 1,151fish measured by both anglers and creel survey anglers. The top three species measured include scup (402 lengths), bluefish (241lengths) and sea robins (236 lengths).
- Providing a 1 " lower minimum length for scup has allowed anglers to take home $40 \%$ more fish from these sites ( 124 of 229 fish harvested were between 9 and almost 10 inches). Also, having a 2 " lower minimum length for summer flounder has provided anglers with $22 \%$ more fish at keeper length (17 of 21 fish harvested were between 16 and almost 18 inches).

## Conclusions:

- Providing anglers with a lower minimum length for both summer flounder and scup has enhanced opportunity along the Connecticut shore and allowed anglers to keep more fish for consumption.

## Recommendations:

- Continue creel sampling across Enhanced Shore Fishing sites to monitor shore fishing activity and the effects of different minimum sizes for both scup and summer flounder at these sites. Sampling levels will be curtailed in 2016 due to the Division's increased involvement in the Marine Recreational Information Program (MRIP).

## Job 4: Tackle Shop Coop Survey

## INACTIVE

## Job 5: Marine Finfish Survey - Long Island Sound Trawl Survey (LISTS)

Goal: To provide long term monitoring of abundance, biomass and size composition of marine fishery resources along with environmental parameters, in order to evaluate the effects of fishing and environmental conditions on the distribution and abundance of living resources in Long Island Sound.

## Key Findings:

- The full complement of 120 spring and 80 fall trawl survey samples was completed in 2015.
- The total fish species count (66) is above the 32- year average of 57.6 species per year (1984-
2014), ranking $3^{\text {rd }}$ overall. In addition, the 2015 survey documented 43 invertebrate species, egg deposition of four species (e.g. squid, whelk), seven plants and one reptile (see bullet on endangered species interactions).
- The total fish count was 163,221 weighing $15,625.2 \mathrm{~kg}$. Only a subset of invertebrates are counted (lobsters, blue crab, squid, horseshoe crab, mantis shrimp...) while all invertebrate species are quantified by a total weight for each species in each tow. The total invertebrate count (of those enumerated) was 29,150 while the total weight of all invertebrates collected in 2015 was $1,958.6 \mathrm{~kg}$. These values are within the range observed historically.
- $\quad$ Scup abundance (geometric mean count per tow (geomn) $=422.2$ ) was the highest since 2007 and the fifth highest abundance recorded since 1984. Black sea bass abundance (1.94) in 2015 was the second highest recorded, exceeded only by the 2014 index of 2.73 (geomn). Sea bass abundance since 2012 has exceeded levels seen at any time between 1984 and 2011. Smooth dogfish (smooth hound) abundance, like black sea bass has increased dramatically since 2012 reaching record abundance in 2015 (geomn=7.3). Other species at record abundance include northern kingfish, Atlantic menhaden, Striped sea robin (2015 rank= $2^{\text {nd }}$ after 2012).
- Record low abundances of windowpane flounder and winter flounder, little skate and American lobster were recorded in 2015, continuing long term declining trends in these species.
- Endangered Species Interactions: Two species, one Atlantic sturgeon and one Kemp’s ridley sea turtle (Length 310 mm , Width 310mm), were captured on two of the 200 tows completed in 2015. This is the first Kemp's ridley encounter for the survey. Both captures were reported to NMFS within 24 hours as required under the conditions of our authorization to conduct sampling activities.

## Conclusions:

- The abundance of some recreationally important species in Long Island Sound remains moderate to high including scup, striped bass, summer flounder and black sea bass. However, some recreational species like winter flounder and tautog have gone through a protracted period of declining abundance and this is cause for concern. Additionally, several species not typically targeted by recreational fishermen have undergone changes in abundance in trawl survey catches which are consistent with broad scale increasing temperature trends in the northwest Atlantic.

## Recommendation:

- Continue this broad scale living marine resource monitoring of Long Island Sound begun in 1984.

## Job 6: Studies in Conservation Engineering

Goal: The original goal, "to develop a better understanding of fishing gear performance, including differences in gear technology and associated change of size and species selectivity," has been modified to "evaluate new technology for potential inclusion in the Long Island Sound Trawl Survey."

## Key Findings:

- The main impetus for evaluating the performance of different fishing gear as stated in the original goal was prolonged difficulty in acquiring the same style doors that the Long Island Sound Trawl Survey (LISTS) had been using since 1984. Ultimately, a new vendor for the old style doors was found, therefore, the decision was made to not make any significant changes to the door and net configuration at this time. This eliminates the need to evaluate any potential change in fishing efficiency and avoids any risk of affecting the consistency of LISTS’s valuable long timeseries.
- Instead of investigating different nets or doors, efforts focused on evaluating new components for an onboard electronic data acquisition system for fisheries research to modernize LISTS data collection and data entry.
- Bluetooth and wireless technologies have continued to improve over the years to the point where it may now feasible to have an electronic data acquisition system for a relatively small vessel like the R/V John Dempsey where there is insufficient space for permanently hardwired electronic or computerized equipment on deck and where the deck layout has to be completely changed ten times a year to accommodate a different survey.
- Several components for an electronic data acquisition system for the Long Island Sound Trawl Survey have been evaluated and selected for purchase: electronic measuring boards, tablets, weighing scales and printers.

## Conclusions:

- With continued development of Bluetooth and wireless technologies (improved performance and reduced cost), it now seems feasible to incorporate components of an electronic data acquisition system into the Long Island Sound Trawl Survey (LISTS).

## Recommendations:

- Continue to evaluate new technologies as needed and, after successful vetting, incorporate into existing surveys as time and funding permits. Continue investigation and development of software to integrate new hardware components with a new database for LISTS.

Job 7: Alosine Survey
INACTIVE

## Job 8: Estuarine Seine Survey

Goal: To monitor the abundance and size composition of near-shore young-of-year and forage fish resources, with physical habitat parameters, in order to evaluate the effects of fishing and environmental conditions on the distribution and abundance of marine resources in Long Island Sound.

## Key Findings:

- A total of 48 seine hauls were taken in September 2015 at eight sites, yielding a total catch of 11,132 fish of 27 species and 16,966 invertebrates of 11 species.
- The 2015 annual index of recruitment for young-of-year winter flounder ( 0.6 fish/haul) ranked fourth lowest out of 28 annual indices.
- Mean catch of all finfish (330fish/haul) was the highest in the 28 year time series and more than double the time series median of 135 fish/haul. Geometric means were calculated for 22 species commonly captured in the survey since it began in 1988.
- An index of forage abundance was generated using the catch of four of the most common forage species caught: Atlantic silversides, striped killifish, mummichog, and sheepshead minnow. The index for 2015 ( 171 forage fish/haul) was the second highest of the 28-year series, and well above the time series median of 102fish/haul.
- YOY scup, black seabass, tautog, and bluefish indices reflect record high abundance in 2015.
- A total of 396 seine hauls were taken monthly, June - September, 2013-2015 at six of the eight seine sites that were unchanged physically since similar samples $(\mathrm{N}=415)$ were taken in 1988-1990 in the same months. YOY winter flounder abundance was highest in June and declined over the summer during both time periods. Although abundance in June was similar for both time periods, attrition from July-September in 2013-2015 was more than five times greater compared to the same months in 1988-1990.
- Over the 28-year time series, the mean number of cold temperate species captured per haul was less than three with a negative trend while the mean number of warm temperate species increased significantly from about three to more than seven.

## Conclusions:

- Juvenile abundance of many recreationally important species in Long Island Sound continues to increase, as does the diversity of forage and other finfish and invertebrates. This trend demonstrates the important role the Sound plays as a nursery and feeding ground. However, some recreational species, especially winter flounder, have gone through a protracted period of declining abundance and this is cause for concern.

## Recommendations:

- Continue this inshore monitoring survey of marine fishery resources of coastal Long Island Sound which began in 1988. An extended time series is a necessary context for assessment of successful reproduction and recruitment.

## Job 9: Volunteer Estuarine Fisheries Database

Goal: Identify estuarine nearshore waters critical to the production and growth of recreationally important finfish for the purpose of protecting and enhancing these populations in shallow water
habitats and promote citizens' greater understanding and appreciation of local marine resources through participation in local volunteer survey projects.

## Key Findings:

- Marine Fisheries staff continued working with three citizen's group gathering fisheries and water quality data. Data from the Maritime Aquarium Marine Life Study cruises off Norwalk and the US Coast guard Academy Thames River Survey were added to Harbor Watch (Norwalk), Cedar Island Marina Research Program (Clinton) and Project Oceanology (CT River).
- Data from these programs provide further evidence of rising water temperature and coincident shifts in species composition and abundance.
- Harbor Watch beam trawl sampling captured 5-15 finfish species annually for years with comparable effort in June through October, modestly increasing in 2015 when 499 fish were caught of 17 species. In 2015, winter flounder were captured in 18 of the 19 grids sampled and their number/tow were the highest recorded since 2005. Flounder were most abundant in the lower harbor, a distribution that differed from the early 1990s when the species was most abundant in the upper harbor

## Conclusions:

- Volunteer effort by citizen groups provides valuable complementary information on Connecticut estuarine resources, including in areas not directly sampled by DEEP.

## Recommendations:

- Maintain working relationships with these groups and encourage their continued volunteer efforts monitoring environmental health in nearshore waters.

## Job 10: Cooperative Interagency Resource Monitoring.

Goal: To monitor the physical, chemical and biological indicators of environmental conditions in Long Island Sound.

## Key Findings:

- Eight cruises were completed from May 28 September16, 2015 between 28 May and 16 Over the season, five stations were documented as hypoxic and of the 252 site visits completed, hypoxic conditions were found four surveys.
- Summer hypoxia ( $\mathrm{DO}<3.0 \mathrm{mg} / \mathrm{l}$ ) in 2015 was very limited, impacting the second smallest area since the survey began in 1991.
- Severe hypoxia ( $\mathrm{DO}<1.0 \mathrm{mg} / \mathrm{l}$ ) was not detected at all in 2015. Moderately severe hypoxia (DO $1.0<2.0 \mathrm{mg} / \mathrm{l}$ ) was limited to the New York waters of far western Long Island Sound from approximately Oak Neck LI (south of Greenwich CT/ Rye NY border) to Execution Rocks.
- Early season (May) bottom water temperatures were well below average following an unusually
cold winter, but rose quickly to above average by early July, remaining above average through the hypoxia monitoring season in early September.

## Conclusions:

- Hypoxia impacts on living marine resources were minimal in 2015 given dissolved oxygen concentrations remained above $3.5 \mathrm{mg} / \mathrm{l}$ through the entire Sound east of Greenwich CT.

## Recommendations:

- Maintain the Long Island Sound Water Quality / Hypoxia Monitoring Program.

## Job 11: Public Outreach

Goal: To increase awareness among anglers and the general public of fisheries information provided by this project and how this information contributes to state and federal efforts to enhance, restore and protect marine habitat and recreational fish populations.

## Key Findings:

- A total of 17,296 outdoor and environmental writers, marine anglers and boaters, marina operators, fishing tackle retailers, Fisheries Advisory Council (FAC) members, students, and members of the general public attended outreach events. The importance of research and monitoring to good fisheries management was incorporated into the programs.
- These same audiences also learned that good water quality and proper pollution prevention (nonfishing impacts) are essential to good fisheries habitat management.
- Total attendance at five engagements with sportsmen clubs and other recreational environmental clubs was 233. The audience was encouraged to become actively involved in the fishery management process by attending public hearings and FAC meetings. Notices of public hearings were sent to hundreds of tackle shops and various media outlets including the DEEP website (www.ct.gov/deep/fishing).
- Total attendance at one career day event with a Connecticut college was 52. The students were encouraged to become actively involved in fisheries biology and management.
- The message that the majority of marine finfish research and monitoring are funded through Federal excise taxes on fishing and motorboat fuels was emphasized at major department outreach events.

## Conclusions:

- Large numbers of anglers and members of the general public are provided information about Marine Fisheries programs through participation in outdoor fishing \& hunting shows, Science and Career Days, public speaking engagements and displays at the Marine Fisheries Office.

## Recommendations:

- Continue outreach efforts.

## Job 12: Marine Fisheries GIS.

Goal: To maintain a geographic information system (GIS) of Project data to support map applications and geospatial analyses needed to assist with planning and executing Marine Fisheries Division surveys that support sport fish restoration goals.

## Key Accomplishments:

- GIS Staff created map summaries of tautog (blackfish) catch and release tag data from volunteer anglers. The maps were useful in illustrating that the majority of tautog recaptured had been tagged in the same general area where they were released.
- Spatial depictions of the magnitude of tautog harvest by MRIP sample site, symbolized by fishing distance from shore, and maps showing the distribution of recreation tautog harvest were used to propose a new management area for tautog to include both CT and NY waters of LIS.
- A series of maps were created to illustrate the movement of the mean center annual recreational catch and harvest of black sea bass along the northeastern coast of the United States. These maps show that the mean centers of catch rates are shifting northward from New Jersey toward the southern coast of Long Island Sound, possibly indicating a range expansion for this species.
- Data from the Estuarine Seine Survey were used to generate maps of forage fish indices for 5-year intervals, 1988-2012. The highest indices of abundance were typically in the east, although more recent time periods show moderate abundances in the west as well.
- Spatial analyses of data generated by a temperature model developed by CT DEEP, Stevens Institute and NOAA/NMFS show the amount and distribution of habitat in LIS suitable for warm temperate Mid-Atlantic fish species will likely increase (both in area and amount of time) in the future..

## Conclusions:

- The implementation of a job focused on developing GIS at Marine Fisheries Division allowed staff to benefit from spatial depiction and analyses for a variety of Agency and Project related goals.
- Providing maps to users such as: recreational angler groups, Federal agencies, and regional planning committees, has been an effective way of providing Connecticut's sport fish restoration information to the public.

## Recommendations:

- Continue to assist Marine Fisheries Division projects that support sport fish restoration goals through the use of GIS data and software.

## JOB 1: MARINE ANGLER SURVEY

## GOAL

## To collect marine recreational angler fishing information in the boat mode through a voluntary catch card survey program.

## OBJECTIVES

Provide estimates of:

1) Length-frequency distribution of harvested black sea bass, bluefish, scup, winter flounder, summer flounder, tautog, striped bass, and weakfish.
2) Length-frequency distribution of discarded black sea bass, bluefish, scup, winter flounder, summer flounder, tautog, striped bass, and weakfish.
3) Targeted catch/effort of black sea bass, bluefish, scup, winter flounder, summer flounder, tautog and striped bass.
4) Percent of targeted trips by species.

## INTRODUCTION

CT DEEP has collected marine recreational fisheries information along the Connecticut coastline since 1979 under several state and federal programs. In 2013-2015, NMFS assumed full angler survey responsibility for the federal Marine Recreational Information Program (MRIP) while DEEP continued to manage the site registry. Beginning in 2014, the Marine Angler Survey shifted focus to collection of length frequency of both harvested and released fish to supplement the MRIP survey. Length frequency data that includes released fish is difficult to obtain through traditional access point intercept surveys such as MRIP and is particularly important to effective stock assessments. In addition, this program is designed to better characterize the private boat mode which lands a substantial proportion of fish caught in the Connecticut (85\% in 2012).

## METHODS

Marine recreational fishing information was collected through a voluntary catch card program. Post-marked daily catch cards (Figure 1.1) were distributed to anglers departing from selected private boat sites with high activity to maximize catch card distribution. Boat-based anglers at these selected fishing sites were recruited by DEEP staff to voluntarily report their fishing trip effort information and collect length measurements on fish caught, including both kept and released fish (discards). Each participating boat angler or angler group was given a waterproof daily catch card, pencil, and measuring tape in addition to verbal instructions. Anglers were encouraged to mail the post-marked catch cards upon trip completion or leave them in designated drop-off-boxes installed at key fishing sites. Each card issued had a unique identification number printed on it and all cards given out to anglers was accounted for through the card ID number. As an incentive to maximize participation, anglers entering their Conservation ID/Fishing License Number would be eligible for wining a raffle prize at year's end.

Anglers were requested to provide the following information:

- Date of Trip (mm/dd)/Trip Start Time (check box AM/PM)
- Conservation ID/Fishing License Number
- Primary Fish Targeted
- Secondary Fish Targeted
- Total Hours Fishing (lines wet)
- Areas Fished (see map)
- Number of Anglers that Caught Fish
- Number of Anglers in Fishing Party
- Boat's Total Catch for Trip
o Total Number of Fish Caught and Disposition (Kept/Released)
- If No Fish Caught -Check Box
- Length of First 8 Fish Caught
o Common Fish Name, Length, Disposition (Kept/Released)
Anglers were instructed to measure each fish to the nearest $1 / 2$ inch (rounded down) and record disposition by circling either Y (yes) or N (no) in the Kept column. Fishing boat vessel registration was also requested. All data were entered and stored in an electronic database.

## RESULTS AND DISCUSSION

DEEP staff completed 788 interviews and distributed 947 catch cards to boat based anglers at launch sites equally distributed in eastern and western portions of the state ( 441 interviews, 478 cards east of CT River; 347 interviews, 469 cards west of New Haven). A total of 168 cards were returned (18\%) with 510 anglers reporting their fishing trip activities. Of the 510 anglers, 395 ( $77 \%$ ) caught at least one fish. A total of 1,229 (43\%) fish were kept and 1,655 ( $57 \%$ ) fish were released (Table 1.1) including 19 finfish species or species groups. In addition, a catch of 17 blue crab was reported (of which 15 were kept), along with a few green crabs and spider crabs which were released. The catch data from eastern and western sites were examined separately to address concerns that there was a difference in angler catches in the eastern versus western Long Island Sound that was not clear when coast-wide catches were grouped (Table 1.2). Catch and disposition of most species were similar between regions with the exception of summer flounder that were more prevalent in the east and striped bass that were more prevalent in the west, with a higher percentage released.

Volunteer anglers measured a total of 2,876 fish in 2015, or nearly twice the number measured in 2014. The targeted species (black sea bass, bluefish, scup, striped bass, tautog, summer and winter flounder) accounted for $95 \%$ of the measured catch (Table 1.3). Length frequencies of tautog captured in the eastern versus western Sound were similar while the most common size of black seabass measured in the east was an inch smaller than the most commonly caught seabass in the west (Figure 1.2).

## JOB 2: VOLUNTEER ANGLER SURVEY

GOAL
To enhance the fisheries management process by providing supplemental catch, effort and size composition data for several important recreational finfish species through a voluntary logbook program.

## OBJECTIVES

Provide estimates of:

1) Size composition for both kept and released bluefish, striped bass and other common species.
2) Catch frequency by trip for both kept and discarded fish.

## INTRODUCTION

The Connecticut Volunteer Angler Survey (VAS) program has been in existence since 1979. Its primary purpose is to supplement the National Marine Fisheries Service, Marine Recreational Fishery Statistics Survey/Marine Recreational Information Program by providing additional length measurement data. The Survey emphasizes measurements of fish that are released which are under reported in the federal surveys. The survey's initial objective was to collect marine recreational fishing information concerning finfish species with special emphasis on striped bass. In 1994, the collection of bluefish length measurements was added to the survey to fully document that fishery. In 1997, length data for other marine finfish were added to the Survey.

## METHODS

The VAS is designed to collect trip and catch information from marine recreational (hook and line) anglers who volunteer to record their fishing activities by logbook. The logbook format consists of recording fishing effort, target species, fishing mode (boat and shore), area fished (subdivisions of Long Island Sound and adjacent waters), catch information concerning finfish kept (harvested) and released, and length measurements. Instructions for volunteers are provided on the inside cover of the postage paid logbook. Each participating angler is assigned a unique numeric code for confidentiality purposes. After the logbook data are entered into the Survey database, logbooks were returned to each volunteer for their personal records. Furthermore, to improve communications with recreational anglers and to encourage more public participation, volunteers are notified of upcoming public hearings including proposed and final changes in recreational fishing regulations.

In 2013 the VAS program was incorporated into the Atlantic Coastal Cooperative Statistics Program (ACCSP) Standard Atlantic Fisheries Information System (SAFIS) eLogbook application. Under the ACCSP eLogbook application, the VAS database was upgraded from the previous outdated software. The VAS logbook format was slightly modified so that the information collected would be compatible with ACCSP minimum data element standards (Appendix 2.1). Initially one of the primary purposes of incorporating the VAS database into ACCSP SAFIS was to enable anglers to enter their own fishing information and compile their own
statistics using eLogbook. However, a data entry problem occurred concerning the 'fishing area’ field. Because of the unique geographic location of Connecticut's shoreline, marine anglers often fish over multiple areas crossing interstate and federal boundaries during a single trip. Unfortunately, eLogbook software did not allow entry of data from fishing areas outside of Connecticut's marine waters. Therefore, as in previous years, paper logbooks were distributed to Survey volunteers and Marine Fisheries staff completed VAS data entry. The problem was resolved in 2014, but only a portion of the volunteers entered their own data in 2014 and 2015, with the remainder submitting paper logbooks.

Since the Survey began in 1997, the number of participants has ranged from 18 anglers participating in 1979 to 115 anglers in 1997. Advertising the VAS program through the annually published Connecticut Angler's Guide and on the state web site (www.ct.gov/deep/fishing) has helped increase volunteer participation. The guide is distributed to anglers purchasing Connecticut fishing licenses in addition to being circulated by bait and tackle shops and other entities.

## RESULTS AND DISCUSSION

In 2015 a total of 33 anglers participated in the program, making 762 trips for an average of 23 trips each (Table 2.1). Two-thirds (22) VAS angler's entered their own data through the eLogbook application on the ACCSP website (www.accsp.org) in 2015, an increase from 12 anglers who did so in 2014 which was the first year of the eLogbook program. Most of the anglers that entered their own data expressed favorable comments toward the program.

The private boat mode comprised the most trips (60\%) recorded, followed by shore based trips ( $36 \%$, see Job 3 for description of regular and enhanced shore sites). Of the total, $76 \%$ of the fishing trips caught fish. VAS anglers recorded their catch of 20 species from near shore species to open ocean pelagic species (Table 2.2), including seven principal recreational species currently under a fisheries management plans comprising 79\% of their total catch. With the exception of Atlantic menhaden and hickory shad, the release rate for all species was $50 \%$ or greater.

VAS participants measured over $90 \%$ of their total catch of 8,216 fish, and $100 \%$ of the seven principal species they caught ( $\mathrm{N}=6,502$, Table 2.3). These data show a wide range in the release rate of the principal species, for example $67 \%$ of scup caught by private boat anglers were released while $99 \%$ of summer flounder caught by regular shore based anglers were released. For bluefish with no minimum legal size, the release rate varied from $81 \%$ for private boat anglers to $32 \%$ for all shore based anglers (Figure 3.1).

## CONCLUSIONS

VAS anglers provide valuable recreational fisheries catch data at a relatively low cost. In addition, the length data on released fish provided by this program is difficult or unattainable through conventional access point angler intercept surveys and is essential to effective assessment of the recreational fishery coastwide and in Connecticut. Any anglers interested in participating in the program can contact David Molnar at 860-434-6043, or e-mail address: david.molnar@ct.gov or writing to State of Connecticut, DEEP, Marine Fisheries Office, P.O. Box 719, Old Lyme CT 06371.

## MODIFICATIONS

None.

## ACKNOWLEDGEMENTS

We very grateful to all anglers who have participated in the survey. Without their cooperation and assistance, the VAS program would be not possible.

## JOB 3: ENHANCED OPPORTUNITY SHORE FISHING PROGRAM

## GOAL

To maintain and improve the fishing experience, opportunity and quality of access to public trust marine fisheries resources in Connecticut especially in urban areas, while maintaining marine fish conservation objectives.

## OBJECTIVES

1. Preserve the quality of shore fishing opportunity for species whose management is heavily minimum size dependent, while also meeting fishery management plan conservation objectives.
2. Collect data from the designated enhanced shore fishing sites necessary to gauge the biological and social impact of enhanced opportunity and whether fishery management plan harvest targets are still being met.
3. Create an "adopt-a-shore-site" relationship with tackle shops that are located near specific sites to help maintain and manage locations.
4. Establish contacts with local officials of town owned sites especially within urban areas to increase awareness and appreciation of quality shore based recreational fishing opportunity in their community.
5. Increase public awareness of the sites to encourage activity by increasing communication with tackle shops and anglers.

## INTRODUCTION

DEEP Marine Fisheries has identified the need to enhance fishing opportunity for shore based anglers. Additionally, the Atlantic States Marine Fisheries Commission (ASMFC) Summer Flounder, Scup and Black Sea Bass Management Board requested that DEEP increase monitoring of the enhanced shore fishing sites to provide additional catch information for stock assessments. To meet both these needs, the agency designated shore based fishing sites (see Appendix 8.1) that allowed for less restrictive fishing regulations. Anglers fishing from designated enhanced opportunity shore fishing sites in 2015 were allowed to harvest scup at 9 inches minimum length (vs. 10.5 inches in other private fishing modes and 11 inches for party/charter modes) and summer flounder at 16 inches (vs 18 inches for other modes). The smaller minimum sizes were adopted out of concern that shore anglers were taking a disproportional share of conservation burden associated with the increased minimum sizes adopted in response to the harvest limits established under the joint ASMFC/MAFMC fishery management plans for these species.

A voluntary daily angler catch card program was developed to collect fishing trip and catch information, including length measurements of harvested and released (discarded) fish, from recreational anglers at enhanced shore fishing sites. Collecting length measurement data, especially on discarded fish, is extremely difficult to obtain through traditional access point angler intercept surveys (e.g. MRIP). In past years, such length data has been successfully collected
utilizing volunteer anglers to report their fishing trip information through a logbook survey (VAS, Job 2) and this program was used as a template for the more extensive catch card program (see Appendix 3.2).

## METHODS

Five assignment zones were established comprising a total of 39 sites from Stonington to Norwalk (Figure 3.1). For each assignment, the zone, time of day (am or pm), starting site and direction of travel was randomly selected using the SAS 'ranuni' function. Upon arriving at a site, the creel agent would record:

- Date and time of creel agent arrival
- Weekend or weekday
- Site name
- Initial count of angler(s)
- Arrival and departure time of additional anglers
- Date and time of creel agent departure

Each angler was asked to participate in an angler survey to provide fishing effort and catch information. If they agreed, the creel agent would perform a partial trip interview. The following questions were asked:

- What time did you start fishing?
- Have you been interviewed by this program already this year?
- What species are you fishing for?
- How Many times do you go saltwater fishing per year?
- Of those, what percent are from shore?
- Are there any comments you would like to make about shore fishing in CT (Pro's or Con's).
- Have you caught any fish yet on this trip? If yes, how many fish of each species did you catch?

All fish caught while the creel agent is on site, are measured and recorded. To capture the remaining catch and effort information, each participating angler was provided a waterproof daily catch card, pencil, measuring tape, and verbal instructions were given by DEEP staff. Anglers were asked to fill out the following (data fields):

- Conservation identification number (fishing license number)
- Primary target species
- Secondary target species
- Total hours spent fishing
- Date ( $\mathrm{mm} / \mathrm{dd} / \mathrm{yy}$ )/start time (check box AM/PM)
- Total number of fish kept and released by species
- Length measurements for the first seven fish caught.

Anglers were encouraged to mail in the post-marked catch card, or deposit it into designated drop-off-boxes installed at fishing sites, upon trip completion. Also, questions concerning the survey could be answered by contacting the DEEP Marine Headquarters office.

## RESULTS AND DISCUSSION

Catch cards distributed to shore anglers were categorized by identification number, date, and enhanced shore fishing site code. From May-December 2015 there were a total of 219 assignments (Table 3.1) totaling 1,462 sites sampled (Table 3.2) in five zones. The largest number of intercepts and interviews occurred in August (Table 3.3).

A total of 1,736 cards were distributed to anglers at enhanced shore fishing sites and 682 (39\%) were returned. The reported catch included 26 species/taxonomic groups totaling 1,434 fish (Table 3.4) similar to the total for partial interviews. Half of the fish (54\%) were released due to regulatory discard or undesirable catch. The total harvest reported was 654 fish comprised of 11 species.

## Length Information

Each individual angler reported common name(s) of the first seven fish captured regardless of species and size. A total of 1,151 fish measurements were received, comprised of 18 species (Table 3.5). Bluefish, scup, striped bass and summer flounder were the most frequently harvested and measured by anglers (Figure 3.1), and comprised $67 \%$ of the total measured catch.

## Enhanced shore fishing

Although sample sizes are small, data gathered from this program indicates that the reduced minimum length requirements at the Enhanced Sites improved success rate for shore scup anglers by $40 \%$ compared to anglers complying with legal minimum length requirements. This increase is a near doubling of the $21 \%$ recorded in 2014, the first year of the program. Shorebased summer flounder anglers improved their success rate by $22 \%$ compared to anglers complying with legal minimum length requirements, similar to the $29 \%$ increase recorded in 2014.

## MODIFICATIONS

No modifications are expected.

## JOB 5: LONG ISLAND SOUND TRAWL SURVEY (LISTS)

## CRUISE RESULTS FROM THE 2015 <br> SPRING AND FALL SURVEYS

## STUDY PERIOD AND AREA

The Connecticut DEEP Marine Fisheries Division completed the thirty-second year of the Long Island Sound Trawl Survey in 2015. The Long Island Sound Trawl Survey encompasses an area from New London to Greenwich, Connecticut and includes waters from 5 to 46 meters in depth in both Connecticut and New York state waters. Typically, Long Island Sound is surveyed in the spring, from April through June, and during the fall, from September through October. This report includes results from the 2015 spring and fall sampling periods and provides time series information since the commencement of the survey in 1984.

## GOAL

To provide long term monitoring of abundance, biomass and size composition of marine fishery resources along with environmental parameters, in order to evaluate the effects of fishing and environmental conditions on the distribution and abundance of living resources in Long Island Sound.

## OBJECTIVES

Provide:

1) Annual indices of counts and biomass per standard tow for 40 common species and age-specific indices of abundance for winter flounder, tautog, scup, summer flounder, bluefish (Age 0, 1+) and weakfish (Age 0, 1+).
2) Length-frequency distributions of bluefish, scup, summer flounder, winter flounder, tautog, striped bass, weakfish, black sea bass, and other ecologically important species.
3) Annual total counts and biomass for all finfish species taken and annual total biomass for all common macro-invertebrate species taken.
4) Species list for Long Island Sound based on LIS Trawl Survey sampling, noting the presence of additional species from other sampling conducted by the Marine Fisheries Division.
5) Fishery independent survey data to cooperative state researchers or agencies, such as the National Marine Fisheries Service, Atlantic States Marine Fisheries Commission, New England and Mid-Atlantic Councils, and researchers associated with state or local universities

## INTRODUCTION

The Long Island Sound Trawl Survey (LISTS) was initiated in 1984 to provide fishery independent monitoring of important recreational species in Long Island Sound. A stratifiedrandom design based on bottom type and depth interval was chosen and forty sites were sampled monthly from April through November to establish seasonal patterns of abundance and distribution. Seven finfish species were initially of primary interest: bluefish, scup, striped bass, summer flounder, tautog, weakfish, and winter flounder. Length data for these species were collected from every tow; scup, tautog, and winter flounder were sampled for aging. Lobster were also enumerated and measured from every tow. All fish species were identified and counted.

Since 1984, several changes have been incorporated into the Survey. In 1991, the sampling schedule was changed to a spring/fall format, although sampling is still conducted on a monthly basis (April - June, September, and October). Beginning in 1992, species were weighed in aggregate with an onboard scale to provide indices of biomass. Furthermore, more species have been sampled for lengths, such as windowpane and fourspot flounders, and important forage species such as butterfish, long-finned squid, and several herring species. By 2003, the list of species measured expanded to 20 finfish species and two invertebrate species (lobster and long-finned squid), plus rarely occurring species. Beginning in 2014, lengths were collected from all finfish species on each tow. In addition, age structures were collected from bluefish, menhaden, tautog, scup, winter flounder, weakfish and large summer flounder ( $>59 \mathrm{~cm}$ ). All of these changes serve to improve the quality and quantity of information made available to fishery managers for local and regional assessment of stock condition, and to provide a more complete annual inventory of LIS (Long Island Sound) fishery resources.

## METHODS

## Sampling Design

LISTS is conducted from longitude $72^{\circ} 03^{\prime}$ (New London, Connecticut) to longitude $73^{\circ}$ 39' (Greenwich, Connecticut). The sampling area includes Connecticut and New York waters from 5 to 46 m in depth and is conducted over mud, sand and transitional (mud/sand) sediment types. Sampling is divided into spring (April-June) and fall (Sept-Oct) periods, with 40 sites sampled monthly for a total of 200 sites annually. The sampling gear employed is a 14 m otter trawl with a 51 mm codend (Table 5.1). To reduce the bias associated with day-night changes in catchability of some species, sampling is conducted during daylight hours only (Sissenwine and Bowman 1978).

LISTS employs a stratified-random sampling design. The sampling area is divided into $1.85 \times 3.7 \mathrm{~km}$ ( $1 \times 2$ nautical miles) sites (Figure 5.1), with each site assigned to one of 12 strata defined by depth interval ( $0-9.0 \mathrm{~m}, 9.1-18.2 \mathrm{~m}, 18.3-27.3 \mathrm{~m}$ or, 27.4+ m) and bottom type (mud, sand, or transitional as defined by Reid et al. 1979). For each monthly sampling cruise, sites are selected randomly from within each stratum. The number of sites sampled in each stratum was determined by dividing the total stratum area by $68 \mathrm{~km}^{2}$ ( 20 square nautical miles), with a minimum of two sites sampled per stratum (Table 5.2). Discrete stratum areas smaller than a sample site are not sampled.

## Sampling Procedures

Prior to each tow, temperature $\left({ }^{\circ} \mathrm{C}\right.$ ) and salinity ( ppt ) are measured at 1 m below the surface and 0.5 m above the bottom using a YSI model $30 \mathrm{~S}-\mathrm{C}-\mathrm{T}$ meter. Water is collected at depth with a five-liter Niskin bottle, and temperature and salinity are measured within the bottle immediately upon retrieval.

The survey's otter trawl is towed from the 15.2 m aluminum R/V John Dempsey for 30 minutes at approximately 3.5 knots, depending on the tide. At completion of the tow, the catch is placed onto a sorting table and sorted by species. Finfish, lobsters and squid are counted and weighed in aggregate (to the nearest 0.1 kg ) by species with a precision marine-grade scale (30 $\mathrm{kg},+/-10 \mathrm{gm}$ capacity). Catches weighing less than 0.1 kg are recorded as 0.1 kg . During the initial two years of the survey (1984 \& 1985), lobsters were the only invertebrates recorded. Squid abundance has been recorded since 1986. Since 1992, additional invertebrate species have been weighed in aggregate, and some have been counted. The complete time series of species counted and weighed in the survey is documented in Appendix 5.4.

For finfish species, lengths are recorded to the centimeter as either total length or fork length (e.g. measurements from 100 mm to 109 mm are recorded as 10 cm ) and entered in the database as 105 mm (Table 5.3). Lobsters are measured to 0.1 mm carapace length. Squid are measured using the mantle length (cm), horseshoe crab measurements are taken using prosomal width (cm) and whelk (knobbed and channeled) shell widths are measured in millimeters.

The number of individuals measured from each tow varies by species, the size of the catch and range of lengths (Table 5.3). If a species is subsampled, the length frequency of the catch is determined by multiplying the proportion of measured individuals in each centimeter interval by the total number of individuals caught. Some species are sorted and subsampled by length group so that, for example, all large individuals are measured and a subsample of small (often young-of-year) specimens is measured. All individuals not measured in a length group are counted. The length frequency of each group is estimated as described above, i.e. the proportion of individuals in each centimeter interval of the subsample is expanded to determine the total number of individuals caught in the length group. The estimated length frequencies of each size group are then appended to complete the length frequency for that species. This procedure is often used with catches of bluefish, scup, and weakfish, which are usually dominated by young-of-year or discrete age/length classes.

Bluefish, menhaden, scup, summer flounder, tautog, weakfish (ageing was discontinued in 2013) and winter flounder are sampled for age determination (Table 5.3). The target number of age samples (otolith) for bluefish were 50 from the spring period (defined by ASMFC Bluefish Technical Committee as Jan-July) and 50 from the fall period (August-December). Subsamples of scup, stratified by length group, are measured to the nearest mm (fork length) and scales from each individual are taken for ageing. Scup scales are removed posterior to the pectoral fin and ventral to the lateral line. The scales are pressed onto plastic laminate with an Ann Arbor roller press to obtain an impression of the scale, which is then viewed with a microfiche reader at 21x. Scales are also taken from all summer flounder greater than 59 cm . At least 15 scales are removed from the caudal peduncle area. These scales are pressed and aged to supplement the National Marine Fisheries Service age key and are also included in the formulation of LISTS summer flounder catch-at-age matrix (see below).

Menhaden scales are collected from roughly 50 fish each year as required by Amendment 2 of the ASMFC Atlantic menhaden management plan. Amendment 2 introduced a requirement for biological sampling of the commercial bait harvest to support improved stock assessments. However since Connecticut has such a small menhaden commercial fishery, sampling it would be difficult. The same size/age component of the menhaden population taken in the commercial fishery is available to LISTS so collections are taken as part of each survey cruise. Menhaden fork length (mm), and sex are recorded and scales are taken about mid-body (lateral line) and below the insertion of the dorsal fin. Most tautog taken in LISTS are aged due to the low numbers caught in recent years (under 250 fish). Tautog are iced and taken to the lab, where their total length (mm), sex, and total weight (gm) are recorded and their age is determined from opercular bones (Cooper 1967). At the request of the ASMFC Tautog Technical Committee, LISTS began collecting tautog otoliths in addition to opercles in 2012. Results from a recent ASMFC Tautog Ageing Workshop (May 2012) indicated there was no clear benefit to switching from opercles to otoliths for CT, so tautog otoliths will be collected (minimum of 50 per/ASMFC) and archived for potential use in the future. Subsamples of winter flounder, stratified by length group and area (as listed in bottom of Table 5.3), are iced and taken to the lab where they are measured to the millimeter (total length), weighed (gm) and sexed. Their maturity stage is determined (NMFS 1989), and they are aged with whole and/or sectioned otoliths (Simpson et al. 1988). Weakfish scales were obtained and processed as described above for scup, and, prior to 2013, otoliths were sectioned and read using procedures described in Simpson et al. 1988. However, since the compliance criteria for a number of other species managed through ASMFC Fishery Management Plans have increased to include ageing over the years, coincidence with stagnant (or declining) levels of funding and staff, age structures for weakfish will no longer be collected because it is not required.

In reports prior to 2001, three species were not included in annual and seasonal totals: American sand lance, bay anchovy, and striped anchovy. These species, with the possible exception of striped anchovy, can be very abundant in Long Island Sound, but are not retained well in the otter trawl. Additionally, many of these fish are young-of-year and often drop out of the net as it is retrieved and wound on the net reel. For this reason they were not included in the list of species to be counted when LISTS was started in 1984. However, to document the occurrence of these species in LISTS catches, American sand lance was added in 1994, striped anchovy was added in 1996, and bay anchovy was added in 1998. Since 2001, adults of these three species have been included in the annual and seasonal totals and the young-of-year are listed if present in the year's catch but are not quantified (Table 5.15, Appendix 5.4). Young-ofyear for these three species are included in the database but are cataloged with a separate species identifier and quantities are considered estimates (Appendix 5.2).

Interactions with endangered species during the course of sampling are regulated by the by NOAA Fisheries GARFO Protectected Species Division. Sampling procedures have been modified in recent years to minimize the likelihood of injury to Atlantic sturgeon (an endangered species since 2012). When sampling in a season and area where the chance of catching a sturgeon is high (based on historic LISTS catch) and water depth is greater than 27m, gear retrieval speed is reduced to decrease the stress induced by rapid changes in pressure. When an endangered species is detected in the net, it is removed as quickly and carefully as possible. Subsequent handling and processing of endangered species adhere to the Reasonable and Prudent Measures, as well as, the Terms and Conditions spelled out in the ESA Section 7 Biological

Opinion's Incidental Take Statement issued by NOAA for CT in January 2013 (http://www.greateratlantic.fisheries.noaa.gov/protected/section7/bo/actbiops/usfws_state_fisheri es_surveys_2013.pdf). Additionally, handling and processing of sturgeon follow protocols described in A Protocol for Use of Shortnose, Atlantic, Gulf, and Green Sturgeons (Kahn and Mohead. 2010. U.S. Dep. Commerce, NOAA Tech Memo, NMFS-OPR-45, 62p., http://www.nmfs.noaa.gov/pr/pdfs/species/kahn_mohead_2010.pdf). One Atlantic sturgeon and one Kemp's ridley sea turtle were captured on two of the 200 tows completed in 2015. All interactions with endangered species are detailed in Appendix 5.5.

## Data Analysis

## Indices of Abundance: Annual Mean Count and Weight per Tow

To evaluate the relative abundance of common species, an annual spring (April - June) and fall (September - October) geometric mean number per tow and weight per tow (biomass, kg ) is calculated for the common finfish and invertebrate species. To calculate the geometric mean, the numbers and weight per tow are logged (loge) to normalize the highly skewed catch frequencies typical of trawl surveys:

> Transformed variable = ln(variable+1).

Means are computed on the log scale and then retransformed to the geometric mean:

$$
\text { geometric mean }=\exp (\text { mean })-1
$$

The geometric mean count per tow was calculated from 1984-2015 for 38 finfish species, lobster, and long-finned squid (1986-2015). The geometric mean weight per tow was calculated using weight data collected since 1992 for the same species, plus an additional 13 invertebrates.

For the seven finfish species that were measured on every tow (bluefish, scup, striped bass, summer flounder, tautog, weakfish, and winter flounder) biomass indices were calculated for the years 1984-1991 by using length/weight equations to convert length frequencies to weight per tow. Bluefish, scup, weakfish and winter flounder lengths were converted using equations from Wilk et al. 1978; striped bass conversions were accomplished using an equation from Young et al. 1994; summer flounder and tautog conversions were accomplished using equations developed from LISTS data from 1984-1987 and 1984-1996 respectively.

## Indices of Abundance: Indices-at-Age and Age Group

Annual age specific indices (indices-at-age matrices) were calculated for scup, striped bass, summer flounder, winter flounder and tautog. The age data used to calculate the indices came from three sources: striped bass ages were derived using the von Bertalanffy (1938) equation; summer flounder age-length keys were obtained from the National Marine Fisheries Service (NMFS) Northeast Fisheries Science Center spring and fall trawl surveys combined with LISTS ages ( $>59 \mathrm{~cm}$ ); scup, winter flounder and tautog age-length keys (in 1 cm intervals) were obtained directly from LISTS. Since fish growth can fluctuate annually as a function of population size or other environmental factors, a year and season specific age-length key was used wherever possible. Once lengths have been converted to age, the proportion at age is
multiplied by the abundance index of the appropriate season to produce an index of abundance at age.

Recruitment (young-of-year) and age 1+ (all fish age one and older) indices were calculated for bluefish and weakfish. Observed modes in the length frequencies were used to separate the two groups.

The specific methods used to calculate indices-at-age for each species were as follows:

- Bluefish. Age samples (otoliths) were taken from 157 bluefish, 18 from the spring period and 136 from the fall period. Of the 18 samples taken in the spring, only three (3) were obtained from LISTS; the bulk of the samples came from recreational anglers. All of the fall samples were obtained from LISTS ( 136 fish). No samples were obtained through donations from a fishing tournaments in 2015. In 2012 a coast wide biological sampling program was initiated through ASMFC addendum 1 of the bluefish management plan. Since there is only four years of data from the northeast, there are still limited results available at this time. Therefore, the method of using modes observed in the fall length frequencies to separate bluefish into age 0 and age $1+$ groups, and calculate a geometric mean catch per tow for each group (Table 5.22) was continued through 2015. Comparison of the mean length-at-ages reported for young-of-year and age 1 bluefish in the New York Bight (Chiarella and Conover 1990) and Long Island Sound (Richards 1976) with LISTS length frequencies suggests that bluefish can easily be identified as either age 0 (snapper bluefish) or adults (age 1+). Richards (1976) and Chiarella and Conover (1990) determined that most bluefish less than 30 cm are age 0 . A discontinuity in the LISTS fall length frequencies occurs most years between 26 cm and 39 cm (Table 5.42). Therefore 30 cm was determined to be a suitable length for partitioning age 0 and age one fish. With the addition the biological sampling programs along the coast, a regional northeast key is being compiled through ASMFC..

Prior to 2012, there was limited bluefish ageing in the northeast. Although North Carolina state biologists have aged bluefish for some time, their age keys were not used to age Long Island Sound bluefish because North Carolina mean lengths-at-age are not consistent with modes observed in Long Island Sound bluefish length frequencies. This difference suggests that growth may vary by region, or that early and late spawned bluefish may be differentially distributed along the coast (Kendall and Walford 1979).

- Scup. An index-at-age matrix was developed for 1984-2015 using spring (May-June only) and fall (September-October) LISTS data (Table 5.23). April data was omitted since very few scup are taken at this time. A total of 13,674 scup aged between 1984 and 2015 were used to make year and season specific age-length keys ( 1 cm intervals). In the relatively few instances when the season/year specific key failed at a given 1 cm length interval, a three-year pooled key was used to determine the age. Three-year pooled keys were calculated using the years preceding and following the "run" year. For the terminal year, only two years were used for the pooled key. The final index-at-age was computed for both spring and fall indices-at-age. Since very few scup older than age 9 are taken (less than $4 \%$ in any given year), an age $10+$ group is calculated by summing indices for
ages 10 and up. To represent the full adult portion of the population an age $2+$ index is calculated by summing the indices for ages 2 through $10+$.
- Striped bass. To approximate the ages of striped bass taken in the spring survey (Table 5.24), the average of the Chesapeake Bay and Hudson River striped bass von Bertalanffy parameters ( $\mathrm{L}_{\max }=49.9 \mathrm{in}, \mathrm{K}=0.13$, $\mathrm{t}_{0}=0.16$, Vic Crecco, pers. comm.) were used in the rearranged von Bertalanffy equation:

$$
t=(1 / K) *\left(-\log _{e}\left(\left(L_{\max }-L_{t}\right) / L_{\text {max }}\right)\right)+t_{0}
$$

Since this equation estimates age $t$ as a fraction of a year, the estimates were rounded to the nearest year (e.g. age 3 = ages 2.5 to 3.4). A spring catch-at-age matrix was developed for 1984 through 2014 by apportioning the spring index by the percentage of fish at each age (Table 5.25).

- Summer flounder. The year and season specific age-length keys (1 cm intervals) used to age LISTS catches were provided by NMFS from their spring and fall trawl surveys. These keys were supplemented with fish caught and aged by LISTS (typically 60 cm and over). LISTS also provides the age data from these fish (<60cm) to NMFS. In 2015, LISTS staff decided to collect representative scale samples from smaller fluke, as well, in the effort to create an LIS-specific age-key eventually. Until there are sufficient age samples to create the LIS-specific age-key, an age-key will be constructed using both LISTS and NMFS age data. In 2015; 151 summer flounder, were aged; 27 from the spring ( $5>60 \mathrm{~cm}$ ) and 124 from the fall (one $>60 \mathrm{~cm}$ ). Since 2001, whenever the season/year specific key failed at a given 1 cm length interval a pooled year key using only adjacent years was used (Gottschall and Pacileo 2002). Since it is thought that growth rates for summer flounder have changed over time, a pooled key using only adjacent years would more accurately represent fish that could not be aged by the season/year specific key. Using this methodology, the catch-at-age matrix (Table 5.26) will remain unchanged for all but the terminal year, which will be updated as the following years’ data becomes available.
- Tautog. An index-at-age matrix was developed for 1984-2015 using all survey months (Gottschall and Pacileo 2007) (Table 5.27). During 2015, 304 tautog were captured and opercles were collected from all; 276 collected in the spring and 23 were collected in the fall. Ageing for 2006-2012 has been completed. Preliminary ageing for 2013-2015 samples has been done.
- Weakfish. Age 0 and age $1+$ indices were calculated for both spring (1984-2013) and fall surveys (1984-2009, 2013) (Table 5.28). Since few weakfish are taken in April, the spring geometric mean was calculated using only May and June. All weakfish taken in spring are assumed to be age $1+$. Similar to bluefish, the fall age 0 and $1+$ indices were calculated by using length frequencies to separate the catch. Since a break in the fall length frequencies generally occurs between 24 and 32 cm each year (Table 5.57), weakfish less than 30 cm are considered to be age 0 while those greater than or equal to 30 cm are ages 1+. Ageing for weakfish was discontinued in 2013.
- Winter flounder. An index-at-age matrix was developed for 1984-2015 using April and May LISTS data (Table 5.29). June data were not used since length frequency data suggest that many adult winter flounder have left the Sound by this time (an exception was made for 1984, the first year of LISTS, because very few samples were taken in the spring months). A total of 23,697 winter flounder aged between 1984 and 2015 were used to make year and region (east of Stratford Shoal, west of Stratford Shoal) specific age-length keys in 1 cm intervals. Similar to scup and summer flounder, three year pooled keys using only the adjacent years (two years for the terminal year runs) were used to assign ages if year specific keys were not available.

Each flounder aged as described above was also assessed for maturity stage (following Burnett 1989) by sex. CT DEEP staging of winter flounder was verified in a cooperative study with NMFS in 2009-2010 (Gottschall and Pacileo 2011). The percentage of male and female fish in each centimeter length group that was sexually mature (ripe, resting, or spent) was calculated in order to determine the length group at which $50 \%$ was mature each year.

## Species Richness by Group

The Long Island Sound Trawl Survey monitors species richness using groups of species classified as either cold temperate or warm temperate. For the purposes of tracking species richness, American sand lance, bay anchovy, and striped anchovy were omitted (see Sampling Procedures section). All other finfish species captured in LISTS were divided into groups based on their temperature preferences and seasonal spawning habits as documented in the literature (Collette and Klein-MacPhee 2002, Murdy et al. 1997). Species in the cold temperate group prefer water temperatures below $15^{\circ} \mathrm{C}\left(60^{\circ} \mathrm{F}\right)$, tend to spawn at the lower end of their temperature tolerance range, and are more abundance north of Long Island Sound than south of New York. Species in the warm temperate group prefer warmer temperatures $\left(11-22^{\circ} \mathrm{C}\right.$ or $\left.50-77^{\circ} \mathrm{F}\right)$, tend to spawn in the upper range of their temperature tolerance, and are more abundant south of the Sound than north of Cape Cod (Appendix 5.6). Species that are not tolerant of cold temperatures, are abundant only south of Chesapeake Bay but stray into northern waters mostly as juveniles, and spawn only in the mid-Atlantic Bight and south were placed into a separate group (subtropical) and were not included in the analysis because they are typically only present in the fall LISTS.

## Open Water Forage Abundance

A Long Island Sound open water forage index of abundance was compiled to measure the available food base which supports resident and migratory species within the Sound. This index is formulated as a biomass index that is assembled from 11 of the forage species that are most common in LISTS catches along with three other species that are considered forage at an early life stage (young-of-year, YOY). The species used to generate the index are; Atlantic herring, long-finned squid, butterfish, alewife, blueback herring, American shad, hickory shad, menhaden, whiting, spotted hake, and red hake along with young-of-year stage of scup, bluefish, and weakfish. The geometric mean biomass is calculated using the aggregate of these 14 species on a per tow basis and calculated using the same methodology as described above for individual species biomass indices.

## RESULTS AND DISCUSSION

## Overview of LISTS 2015 Spring and Fall Surveys

Each month of the survey, sampling aboard the R/V John Dempsey generally began in the east end of Long Island Sound and progressed westward. The April survey commenced on April 7, 2015, and continued until April 21 for a total of seven (7) days underway and 40 tows completed. May sampling started on May 11 and continued until May 26 with nine (9) sampling days underway and 40 sites completed. June sampling began on June 10 and ended on June 25, taking ten (10) days underway to complete the 40 sites. The Fall Survey commenced on September 10 and needed ten (10) days underway to complete 40 tows. The 40 sites for October were also completed in ten (10) days. Thus, a total of 200 LISTS tows were completed in 46 days underway during the spring and fall 2015 surveys (Table 5.4); not including transit days or weather days.

Maps showing the sites selected versus the sites sampled during each month of sampling are provided in Figure 5.2 (April), Figure 5.3 (May), Figure 5.4 (June), Figure 5.5 (September) and Figure 5.6 (October). Within each figure the red bordered sites are the sites selected for the month and the solid blue dots indicate the actual sites sampled. If a site had to be relocated during sampling, an explanation of why it was moved is provided under the figure. Additional site/station information is provided in Table 5.5 (April), Table 5.6 (May), Table 5.7 (June), Table 5.8 (September) and Table 5.9 (October). These tables provide date of saple, time, tow duration, latitude/longitude, surface and bottom temperature and salinity, average tow speed, distance towed and approximate area swept for each tow.

Sometimes, a full 30-minute tow cannot be completed. Typical reasons for short tows include lack of room because of observed pot gear set in the immediate area, a drop in speed due to entanglement with some object on the bottom (frequently derelict pot gear), or a complete stop in forward motion (submerged wreck or rock pile). Survey crew will often attempt to finish an interrupted tow by clearing the net (if needed) and resetting beyond the obstruction or observed gear. If this is not possible, a site may have to be moved to another site nearby with the same stratum (bottom type and depth). If the site was moved, the data from the initial site will not be used. Typically, a minimum of $15-20$ minutes is required for a LISTS tow to be recorded. However, there are occasions when a tow with less than 15 minutes will be accepted, usually because there is no alternate site in the designated strata in the vicinity. Short tow information for each month in the 2014 survey is summarized in Table 5.10.

## Cooperative Sample and Data Collection

Throughout the time series, LISTS staff have been participating in cooperative efforts for sample collections, data requests, and special projects using survey personnel, equipment, and other resources. Most of these cooperative efforts are with state researchers or agencies, the National Marine Fisheries Service, Atlantic States Marine Fisheries Commission, New England and Mid-Atlantic Councils, and researchers or graduate students associated with state or local universities. Table 5.11 illustrates many of the organizations that requested data in 2015, while Table 5.12 shows sample request received and fulfilled. In recent years, many requests for samples have come from high schools, aquariums, or other educational organizations needing
finfish and invertebrates for teaching purposes. Additionally, our own staff often have sample or data requests for media or other public outreach events (see Job 11 of this report).

## Number of Species Identified

Sixty-six finfish species were observed in the 2015 Long Island Sound Trawl Survey (Table 5.13). This includes three new species for the survey; red cornet fish (Fistularia petimba), Atlantic threadfin (Opisthonema oglinum) and mahogany snapper (Lutjanus mahogoni). From 1984 to 2015, LIS Trawl Survey has identified one hundred nine (109) finfish species (Appendix 5.1), averaging 58 species per year with a range of 43 to 70 species (Figure 5.7). In addition, a total of 43 types of invertebrates were collected in 2015 (Table 5.14). Most invertebrates are identified to species. However, in some cases, invertebrates were identified to genus or a higher level taxon.

## Total Catch

Appendix 5.4 presents a time series (1984-2015) of the finfish species collected each year and their respective rank by numbers. Annual total biomass of invertebrates is also included in this appendix (1992-2015), ranked by weight (kg). A total of 163,223 finfish weighing 15,625 kg were sampled in 2015 (Table 5.15). A total of 32,937 finfish weighing $7,002 \mathrm{~kg}$ were sampled in spring of 2015 (Table 5.16). A total of 130,289 finfish weighing $8,623 \mathrm{~kg}$ were sampled in fall of 2015 (Table 5.16). A total of $1,959 \mathrm{~kg}$ of invertebrates were taken in 2015 (Table 5.15). The total biomass of invertebrate catch taken in the spring of 2015 was 503 kg (Table 5.17). A total of $1,456 \mathrm{~kg}$ of invertebrates were taken in fall of 2015 (Table 5.17).

## Length Frequencies

Length frequency tables are provided primarily to give the reader an understanding of the size range of various species taken in LISTS. Lengths are converted to age frequencies for analysis of principal species such as scup, bluefish, striped bass, summer flounder, tautog, winter flounder, and weakfish. Changes such as an expansion in the size (age) range for some important recreational species are apparent in recent years including more large scup (Table 5.52-5.53), striped bass (Table 5.54-5.55), and summer flounder (Table 5.56-5.57).

Length frequencies were prepared for 22 species:

| alewife | spring and fall | $1989-2015$ | Table 5.30; |
| :--- | :--- | :--- | :--- |
| American shad | spring and fall | $1989-2015$ | Table 5.31; |
| American lobster | spring and fall (M\&F) | $1984-2015$ | Table 5.32-Table 5.35; |
| Atlantic herring | spring and fall | $1989-2015$ | Table 5.36; |
| Atlantic menhaden | spring and fall | $1996-2015$ | Table 5.37; |
| black sea bass | spring and fall | $1987-2015$ | Table 5.38, Table5.39 |
| blueback herring | spring and fall | $1989-2015$ | Table 5.40; |
| bluefish | spring and fall | $1984-2015$ | Table 5.41, Table 5.42; |
| butterfish | spring and fall | $1986-1990,1992-2015$ | Table 5.43; |
| clearnose skate | spring and fall | $1993-2015$ | Table 5.44, Table 5.45; |
| fourspot flounder | spring and fall | $1989-1990,1996-2015$ | Table 5.46; |

| hickory shad | spring and fall | 1991-2015 | Table 5.47; |
| :--- | :--- | :--- | :--- |
| horseshoe crab | spring and fall (M\&F) | $1998-2015$ | Table 5.48, Table 5.49; |
| long-finned squid | spring and fall | $1986-1990,1992-2015$ | Table 5.50, Table 5.51; |
| scup | spring and fall | $1984-2015$ | Table 5.52, Table 5.53; |
| striped bass | spring and fall | $1984-2015$ | Table 5.54, Table 5.55; |
| summer flounder | spring and fall | $1984-2015$ | Table 5.56, Table 5.57; |
| tautog | spring | $1984-2015$ | Table 5.58; |
| weakfish | spring and fall | $1984-2015$ | Table 5.59, Table 5.60; |
| windowpane flounder | spring and fall | $1989,1990,1994-2015$ | Table 5.61, Table 5.62; |
| winter flounder | April-May and fall | $1984-2015$ | Table 5.63, Table 5.64; |
| winter skate | spring and fall | $1995-2015$ | Table 5.65. |

For the years where length data are available, length frequencies were prepared for the seasons or months for which the preferred indices of abundance and catch-at-age matrices are calculated; for some species length frequencies are provided for both seasons.

## Seasonal Indices of Abundance

The geometric mean count per tow was calculated from 1984-2015 for 38 finfish species plus lobster and long-finned squid (squid since 1986). All spring (April-June) and fall (September-October) data are used to compute the abundance indices presented in Tables 5.18 (spring) and 5.19 (fall), with the preferred seasonal index (for counts) denoted by an asterisk. Geometric mean biomass-per-tow indices have been calculated for 38 finfish and 15 invertebrate species (or species groups) since 1992, for both spring and fall (Table 5.20 and 5.21, respectively). Age specific indices of abundance were calculated for selected important recreational species, including scup, striped bass, summer flounder, and winter flounder (see below). For two other species, bluefish and weakfish recruitment indices were calculated using modal analysis of the length frequencies. For each of the thirty-eight finfish species, plots including catch per tow in numbers and biomass in kilograms are illustrated in Figures 2.8 through 5.13. These figures also include plots of each of the age specific indices and recruitment indices mentioned above. Figure 5.14 provides plots of abundance (biomass) indices for crabs (lady, rock, spider; 1992-2015), American lobster (1984-2015), horseshoe crab (1992-2015), and long-finned squid (1986-2015).

## Indices of Abundance: Important Recreational Species

Spring and fall abundance indices are presented in Tables 5.18-5.19. Indices of abundance at age were also calculated for seven important recreational species: bluefish (Table 5.22 ), scup (Table 5.23), striped bass (Table 5.24 age frequency, Table 5.25 indices at age), summer flounder (Table 5.26), tautog (Table 5.27), weakfish (Table 5.28) and winter flounder (Table 5.29). Bluefish and striped bass indices-at-age are based on the fall and spring surveys, respectively, whereas winter flounder indices-at-age are based on only the April and May cruises of the spring survey. In 2015, LISTS collected otoliths from 429 winter flounder, 425 of which were used in the development of age keys and the final catch-at-age matrix. Both scup and weakfish indices-at-age are calculated and presented separately for each season. Scales from 771 scup were collected and aged in 2014, 764 of which were used in the keys and calculations of the age matrix. Weakfish and bluefish use modal distributions for calculating their respective
recruitment index. Although age structures for bluefish are now being collected, it may take a few years before there is enough age data to construct a robust age key (see methods).

## Winter Flounder Habitat Use

The distribution and demographics of LISTS winter flounder catches were examined for changes related to habitat quality in 2003-2013 compared to 1992-2002 (see Howell et al. 2016). Analysis of variance of individual condition indices (log-log length-weight regression residuals) by sex for post-spawn (resting) mature and immature fish identified consistent and significant differences among six survey strata. Highest condition indices were found in fish captured in shallow ( $<18$ m ) mud, sand, and transitional bottom sediment and deep ( $>18 \mathrm{~m}$ ) mud areas, collectively classified as high quality habitat. Geospatial analyses of catch distribution showed the proportion of the population occupying high quality habitat remained unchanged at $59 \%$ over the time series 1992-2013 even as abundance declined by over $80 \%$. As abundance decreased, condition decreased in mature females, increased in immature fish of both sexes, and was mixed in mature males. Additionally, the proportion mature at length shifted significantly upward for both sexes, back-calculated length-at-age 2 and 3 of mature flounder increased, and estimated winter growth declined for age 3 mature and immature females. The details of these analyses suggest increased competition for prey among mature fish and increased predation pressure on smaller fish. This population may be responding to an increase in the abundance of competing mid-Atlantic species brought about by increasing water temperature coastwide and in LIS. These second order effects may have chronically hindered reproduction and therefore stock rebuilding, especially in areas of low quality habitat.

## Winter Flounder Average Size at Maturity

Average size at maturity for winter flounder captured in April and May cruises has increased since maturation data recording began in 1990. The number mature by cm-interval and sex was calculated for the subset of fish examined in the laboratory each year, and a five-year average computed to maximize sample size. The resulting maturation curves (Figure 5.18) skew right for both sexes from 1990-94 to 2010-2013. The 50\%-midpoint for females has increased from 2426 cm in the 1990 s to 27 cm after 2000. The $50 \%$-midpoint for males has increased from 16 19 cm in the 1990s to $20-22 \mathrm{~cm}$ after 2000. These results indicate not only a larger average size at maturation but also a greater synchronization of the maturation process over a smaller size range.

## Species Richness by Group

The number of cold temperate and warm temperate species captured in each tow was averaged by seasonal cruise (April-June and September-October) for each year from 1984-2015 as an indicator of annual biological diversity or species richness. Trends in these indicators were tested for statistical significance by regression analysis. Results (Figure 5.19) show that the average number of warm temperate species captured/tow in spring and fall cruises has increased ( $\mathrm{F}=26.2$ and 82.8 respectively, $\mathrm{p}<0.0001$ ); while the average number of cold temperate species has decreased, especially in spring ( $\mathrm{F}=43.9, \mathrm{p}<0.0001$ ) but also in fall cruises ( $\mathrm{F}=14.9$, $p=0.0006$ ).

TABLES 5.1-5.29
LISTS

Job 5 Page 15

Table 5.1. Specifications for the Wilcox 14 m high-rise trawl net and associated gear.

| Component | Description |
| :--- | :--- |
| Headrope | 9.1 m long, 13 mm combination wire rope |
| Footrope | 14.0 m long, 13 mm combination wire rope |
| Sweep | Combination type, 9.5 mm chain in belly, 7.9 mm chain in wing |
| Floats | 7 floats, plastic, 203 mm diameter |
| Wings | 102 mm mesh, \#21 twisted nylon |
| Belly | 102 mm mesh, \#21 twisted nylon |
| Tail Piece | 76 mm mesh, \#21 twisted nylon |
| Codend | 18.2 mm mesh, \#54 braided nylon |
| Ground Wires | top legs 27.4 m long, 6 x 7 wire, 6.5 mm diameter diameter |
| Bridle Wires: | 27.4 m long, $6 \times 7$ wire, 11.1 mm, rubber disc type, 40 mm diameter |
| Bottom Legs | Steel "V" type, 1.2 m long x 0.8 m high, 91 kg |
| Doors | $6 x 7$ wire, 9.5 mm diameter |
| Tow Warp |  |

Table 5.2. The number of sites scheduled for sampling each month within the 12 depth-bottom type strata.

|  | Depth Interval (m) |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Bottom type | $\mathbf{0 - 9 . 0}$ | $\mathbf{9 . 1 - 1 8 . 2}$ | $\mathbf{1 8 . 3 - 2 7 . 3}$ | $\mathbf{2 7 . 4 +}$ | Totals |
| Mud | 2 | 3 | 5 | 5 | 15 |
| Sand | 2 | 2 | 2 | 2 | 8 |
| Transitional | 3 | 5 | 5 | 4 | 17 |
| Totals | $\mathbf{7}$ | $\mathbf{1 0}$ | $\mathbf{1 2}$ | $\mathbf{1 1}$ | $\mathbf{4 0}$ |

Table 5.3. Length and age data collected in 2015.
In addition to the species listed below, other rarely occurring species (totaling less than 30 fish/year each) were measured. During 2014, thirty-one other species were measured during LISTS sampling as either rarely occurring species or for other research related projects

| Species measured | Measurement | \# tows/day | \# fish measured |
| :---: | :---: | :---: | :---: |
| Alewife | FL (cm) | All | min of 15 / tow |
| American lobster | CL ( 0.1 mm ) | All | min of 50 / tow |
| American shad | FL (cm) | All | min of 15 / tow |
| Atlantic herring | FL (cm) | All | min of 15 YOY and min of 30 adults / tow |
| Atlantic menhaden | FL (cm) | All | min of 15 / tow |
| Atlantic sturgeon | FL (cm) | All | All |
| Blueback herring | FL (cm) | All | min of $15 /$ tow |
| Bluefish | FL (cm) | All | min of $30 \mathrm{YOY} /$ tow, all adults |
| black sea bass | TL (cm) | All | All |
| butterfish | FL cm) | All | min of 15 YOY and 15 adults / tow |
| cunner | TL (cm) | All | All |
| dogfish, smooth | FL (cm) | All | All |
| dogfish, spiny | FL (cm) | All | All |
| fourspot flounder | TL (cm) | All | min of 30/tow |
| hake, red | TL (cm) | All | min of 30/tow |
| hake, silver (whiting) | TL (cm) | All | min of 30/tow |
| hake, spotted | TL (cm) | All | min of $30 /$ tow |
| hickory shad | FL (cm) | All | All |
| horseshoe crab | PW (cm) | All | All |
| northern searobin | FL (cm) | All | min of 30/tow |
| moonfish | FL (cm) | All | min of $10 /$ tow |
| smallmouth flounder | TL (cm) | All | min of $10 /$ tow |
| striped bass | FL (cm) | All | All |
| striped searobin | FL (cm) | All | min of 30/tow |
| scup | FL (cm) | All | min of 15 YOY and $30 /$ mode for age 1+ |
| long-finned squid | ML (cm) | All | min of $30 /$ tow |
| summer flounder | FL (cm) | All | All |
| tautog | TL (cm) | All | All |
| weakfish | FL (cm) | All | min of $15 \mathrm{YOY} /$ tow, all adults |
| whelk, channeled | PW (mm) | All | All |
| whelk, knobbed | PW (mm) | All | All |
| windowpane flounder | TL (cm) | All | min of 50 / tow |
| winter flounder | TL (cm) | All | min of $100 /$ tow |
| winter skate | TL (cm) | All | All |

| Species aged | Structure | Subsample |
| :---: | :---: | :---: |
| bluefish | scales / otoliths | Collected each season. For each season, minimum of 50 scale and otolith samples collected from full length distribution. Spring collection may use other means of sampling to obtain the required minimum. |
| Menhaden | scales | Collected each season. For each season, minimum of 50 scale samples collected from full length distribution. |
| scup | scales | Collected every month. For each month scales are taken from the following: 3 fish/cm $<20 \mathrm{~cm}$; $5 / \mathrm{cm}$ from $20-29 \mathrm{~cm}$; and all fish $>30 \mathrm{~cm}$. |
| summer flounder | scales | all fish $>=60 \mathrm{~cm}$ |
| tautog | opercular bones | Collected from a minimum of 200 fish/year. |
| weakfish | scales / otoliths | Ageing/collections discontinued in October 2014 |
| winter flounder | otoliths | Collected during April and May from two areas in the Sound: eastern-central and western. For each month and area, subsamples are taken as follows: in the eastern-central area 7 fish / cm $<30 \mathrm{~cm}, 14 / \mathrm{cm}$ from 30-36 cm, all fish $>36 \mathrm{~cm}$. In the western area 5 fish / $\mathrm{cm}<30 \mathrm{~cm}, 10 / \mathrm{cm}$ from $30-36 \mathrm{~cm}$, all fish $>$ than 36 cm . |

Notes: min = minimum; YOY = young-of-year; FL = fork length; TL = total length; CL = carapace length; ML = mantle length; PW = prosomal width.

Table 5.4. Number of Long Island Sound Trawl Survey (LISTS) samples taken by year and cruise.
In 1984, thirty-five sites per monthly cruise from April through November were scheduled for sampling. Starting in 1985, forty sites per cruise were scheduled. In 1991, the Trawl Survey was modified to a spring (April - June) and fall (September - October) format--July, August and November sampling was suspended. In 1993 and 1994 , an additional cruise of 40 sites was added to the fall period. The additional fall cruise was suspended in 1995. One hundred twenty tows were conducted in 2006 due to delays in rebuilding the main engine on the R/V John Dempsey (spring) and mechanical failure/overhaul of the hydraulic power take-off (fall). Delays in overhauling the transmission in the fall of 2008 resulted in missing September sampling. The June cruise and all of fall sampling in 2010 were canceled for an engine replacement in the $R / V$ John Dempsey. Due to delays in engine replacement, begun in 2010 but not completed until late April 2011, April sampling in 2011 was abbreviated.

| Cruise | Year |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 5.5. Station information for LISTS April 2015.
Standard LISTS tows in the spring begin with SP and fall begins with FA. Latitude (N) and Longitude (W) are displayed in decimal degrees. Surface and bottom temperature and salinity are labeled as $S_{-}$and $B_{-}$, respectively. Area swept is estimated by assuming the effective sweep is $2 / 3 r d s$ of the footrope length.

Table 5.7. Station information for LISTS June 2015.
Standard LISTS tows in the spring begin with SP and fall begins with FA. Latitude (N) and Longitude (W) are displayed in decimal degrees. Surface and bottom temperature and salinity are labeled as $S_{-}$and $B_{-}$, respectively. Area swept is estimated by assuming the effective sweep is $2 / 3 r d s$ of the footrope length.

Job 5 Page 21

Table 5.8. Station information for LISTS September 2015.
Standard LISTS tows in the spring begin with SP and fall begins with FA. Latitude (N) and Longitude (W) are displayed in decimal degrees. Surface and bottom temperature and salinity are labeled as $S_{-}$and $B_{-}$, respectively. Area swept is estimated by assuming the effective sweep is $2 / 3 r d s$ of the footrope length.

| Sample <br> Number | Date | Site <br> Number | Bottom Type | Depth Interval | Time <br> Start | $\begin{gathered} \text { Duration } \\ \text { (min) } \end{gathered}$ | Latitude | Longitude | S_Temp (sfc, C) | S_Salinity (sfc, ppt) | B_Temp (btm, C) | B_Salinity <br> (btm, ppt) | Ave Speed (knots) | $\begin{gathered} \text { Distance } \\ \text { (nm) } \end{gathered}$ | Area Swept (sq.nm) |

Table 5.9. Station information for LISTS October 2015.
Standard LISTS tows in the spring begin with SP and fall begins with FA. Latitude (N) and Longitude (W) are displayed in decimal degrees. Surface and bottom temperature and salinity are labeled as $S_{-}$and $B_{-}$, respectively. Area swept is estimated by assuming the effective sweep is $2 / 3 r d s$ of the footrope length

Job 5 Page 23

Table 5.10. Samples with non-standard tow durations and reasons for incomplete tows, spring and fall 2015.
Standard LISTS tows begin with SP (spring) or FA (fall).

| Sample | Date | Site | Bottom Type | Depth Interval | Time | Duration | Reason | Comments |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| APRIL |  |  |  |  |  |  |  |  |
| SP2015001 | 4/7/2015 | 730 | S | 4 | 8:31 | 26 | speed drop | nothing on cables or in net |
| SP2015005 | 4/7/2015 | 828 | S | 3 | 13:39 | 24 | speed drop | nothing on cables or in net |
| SP2015010 | 4/13/2015 | 1737 | T | 1 | 9:53 | 25 | ran out of room | depth ahead was too shallow for stratum |
| SP2015031 | 4/16/2015 | 118 | M | 4 | 14:17 | 24 | pots | string of ghost pots in stbd wing; pots stuck in mud; lots of weight; had to cut; no damage to net |
| MAY |  |  |  |  |  |  |  |  |
| SP2015063 | 5/19/2015 | 620 | M | 3 | 11:03 | 23 | hang | couple of broken tree branches in net \& through meshes; no damage to net |
| SP2015073 | 5/21/2015 | 5709 | S | 2 | 11:08 | 27 | hang | large tree through both wings; net badly torn; had to switch to different net for next tow |
| JUNE |  |  |  |  |  |  |  |  |
| SP2015106 | 6/18/2015 | 5804 | M | 2 | 13:46 | 18 | hang | came to abrupt stop; couple pieces of coral-encrusted wood in net when finally got it on deck; minor damage to net |
| SP2015109 | 6/22/2015 | 110 | T | 3 | 10:19 | 29 | pots <br> pots | active gear wrapped around net; untangled \& let it go hauled back early because saw buoys ahead of us but got lines on |
| SP2015111 | 6/22/2015 | 5612 | T | 2 | 13:44 | 25 |  | both doors anyway because sets were North-South; flipped lines off doors; no pots in net |
| SP2015119 | 6/25/2015 | 1427 | T | 1 | 13:39 | 23 | speed drop | nothing on cables or in net |
| SEPT |  |  |  |  |  |  |  |  |
| FA2015027 | 9/24/2015 | 413 | M | 3 | 8:47 | 20 | pots | one string hanging and one pot in net |

OCT no short tows

Table 5.11. Data requests by month, 2015.

Table 5.12. Sample requests by month, 2015.

Table 5.13. List of finfish species observed in 2015.
Sixty-six finfish species were observed in 2015. (Bold type indicates new species). Since 1984, one hundred-nine species of finfish have been identified in LISTS (see Appendix 5.1 for the full list of species).

| Common Name | Scientific Name | Common Name | Scientific Name |
| :---: | :---: | :---: | :---: |
| anchovy, bay | Anchoa mitchilli | hogchoker | Trinectes maculatus |
| anchovy, striped | Anchoa hepsetus | jack, crevalle | Caranx hippos |
| bigeye | Priacanthus arenatus | kingfish, northern | Menticirrhus saxatilis |
| bigeye, short | Pristigenys alta | lamprey, sea | Petromyzon marinus |
| black sea bass | Centropristis striata | mackerel, Atlantic | Scomber scombrus |
| blue runner | Caranx crysos | menhaden, Atlantic | Brevoortia tyrannus |
| bluefish | Pomatomus saltatrix | moonfish | Selene setapinnis |
| butterfish | Peprilus triacanthus | ocean pout | Macrozoarces americanus |
| cod, Atlantic | Gadus morhua | pipefish, northern | Syngnathus fuscus |
| cornetfish, red | Fistularia petimba | puffer, northern | Sphoeroides maculatus |
| croaker, Atlantic | Micropogonias undulatus | ray, roughtail stingray | Dasyatis centroura |
| cunner | Tautogolabrus adspersus | rockling, fourbeard | Enchelyopus cimbrius |
| dogfish, smooth | Mustelus canis | sand lance, American | Ammodytes americanus |
| dogfish, spiny | Squalus acanthias | scad, bigeye | Selar crumenophthalmus |
| eel, conger | Conger oceanicus | scad, rough | Trachurus lathami |
| filefish, planehead | Monacanthus hispidus | scad, round | Decapterus punctatus |
| flounder, fourspot | Paralichthys oblongus | sculpin, longhorn | Myoxocephalus octodecemspin |
| flounder, smallmouth | Etropus microstomus | scup | Stenotomus chrysops |
| flounder, summer | Paralichthys dentatus | searobin, northern | Prionotus carolinus |
| flounder, windowpane | Scophthalmus aquosus | searobin, striped | Prionotus evolans |
| flounder, winter | Pseudopleuronectes american | shad, American | Alosa sapidissima |
| flounder, yellowtail | Pleuronectes ferrugineus | shad, hickory | Alosa mediocris |
| glasseye snapper | Priacanthus cruentatus | silverside, Atlantic | Menidia menidia |
| goosefish | Lophius americanus | skate, clearnose | Raja eglanteria |
| gunnel, rock | Pholis gunnellus | skate, little | Leucoraja erinacea |
| hake, red | Urophycis chuss | skate, winter | Leucoraja ocellata |
| hake, silver | Merluccius bilinearis | snapper, mahogany | Lutjanus mahogoni |
| hake, spotted | Urophycis regia | spot | Leiostomus xanthurus |
| herring, Atlantic | Clupea harengus | striped bass | Morone saxatilis |
| herring, Atlantic thread | Opisthonema oglinum | sturgeon, Atlantic | Acipenser oxyrinchus |
| herring, alewife | Alosa pseudoharengus | tautog | Tautoga onitis |
| herring, blueback | Alosa aestivalis | toadfish, oyster | Opsanus tau |
| herring, round | Etrumeus teres | weakfish | Cynoscion regalis |

[^0]Table 5.14. List of invertebrates observed in 2015.
In 2015, forty-three invertebrate" species" were identified. In most cases, invertebrates are identified to species; however, species that are very similar are identified to genus, and in difficult cases, to a higher taxon.

| Common Name | Scientific Name | Common Name | Scientific Name |
| :--- | :--- | :--- | :--- |
| Tubularia hydroids | Tubularia, spp. | oyster, common | Crassostrea virginica |
| anemones | anemomes spp. | polychaetes | Class polychfeta |
| arks | Noetia-Anadara spp. | sand dollar | Echinarachnius parma |
| bryozoan, bushy | Phylum Bryozoa | sea grape | Molgula spp. |
| bryozoan, rubbery | Alcyonidium verrilli | sea urchin, purple | Arbacia punctulata |
| clam, common razer | Ensis directus | shrimp, brown | Penaeus aztecus |
| clam, hard clams | Artica-Mercinaria-Pitar sp. | shrimp, coastal mud | Upogebia affinis |
| clam, surf | Spisula solidissima | shrimp, ghost | Gilvossius setimanus |
| coral, star | Astrangia poculata | shrimp, mantis | Squilla empusa |
| crab, mud | Family Xanthidae | shrimp, sand | Crangon septemspinosa |
| crab, blue | Callinectes sapidus | sponge spp. | Crepidula fornicata |
| crab, flat claw hermit | Pagurus pollicaris | sponge, boring | sponge spp. |
| crab, horseshoe | Limulus polyphemus | sponge, deadman's fingers | Haliclona spp. |
| crab, lady | Ovalipes ocellatus | sponge, red bearded | Microciona prolifera |
| crab, rock | Cancer irroratus | squid, longfin inshore | Loligo pealeii |
| crab, spider | starfish spp. | Asteriid spp. |  |
| hydroid spp. | tunicates, misc | misc. class ascidiacea |  |
| jelly, comb | whelk, channeled | Busycotypus canaliculatus |  |
| jellyfish, lion's mane | whelk, knobbed | Busycon carica |  |
| lobster, American | worms, fan | Myxicola infundibulum |  |
| mussel, blue | Phylum Ctenophora | Cyanea capillata | Homarus americanus |
| northern moon snail | Mytilus edulis | Lunatia heros |  |

Names taken from: A Field Guide to the Atlantic Seashore, Peterson Field Guide Series, 1978 (Gosner, 1978).

Table 5.15. Total number and weight (kg) of finfish and invertebrates caught in 2015.
Finfish species are in order of descending count. Invertebrate species are in order of descending weight (nc $=$ not counted). Young-of-year bay and striped anchovy are neither separated by species or quantified; young-of-year Atlantic herring and American sand lance are not quantified. Number of tows (sample size)=200.

Table 5.18. Spring indices of abundance for selected species, 1984-2015.
The geometric mean count per tow was calculated for 38 finfish and 2 invertebrates using April-June data. An asterisk next to the species name and time series mean, indicates that the spring index is a better estimate than the fall index (Simpson et al. 1991). Two asterisks indicate that both the spring and the fall indices provide good estimates.

# Table 5.19. Fall indices of abundance for selected species, 1984-2015. 

The geometric mean count per tow was calculated for 38 finfish and 2 invertebrates using September-October data. An asterisk next to the species name and a time series mean, indicates that the fall index provides a better estimate than the spring index (Simpson et al. 1991). Two asterisks indicate that both the spring and the fall indices provide good estimates. There was no fall sampling in 2010.

Table 5.20. Finfish and invertebrate biomass indices for the spring sampling period, 1992-2015.
The geometric mean weight (kg) per tow was calculated for 38 finfish and 15 invertebrate species for the spring (April-June) sampling period.

|  | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 5.21. Finfish and invertebrate biomass indices for the fall sampling period, 1992-2015.
The geometric mean weight (kg) per tow was calculated for 38 finfish and 15 invertebrate species for the fall (Sept-Oct) sampling period. There was no fall sampling in 2010.

Table 5.22. Bluefish indices of abundance, 1984-2015.
Using September and October length data, the geometric mean catch per tow was calculated for two age groups of bluefish: age-0 and all fish age 1 and older. Age-0 was defined as bluefish less than 30 cm fork length.

| Year | Fall |  |  |  |

Table 5.23. Scup indices-at-age, 1984-2015.
Spring (May and June) and fall (September and October) catch and age data were used to determine the geometric mean indices-atage ${ }^{1}$. The spring and fall age keys were used to expand length frequencies to age frequencies and then the spring and fall overall indices were proportioned by the percentage of fish in each age. The 0-10+ index represents the overall index (sum of ages 0-10+), and the adult $2+$ index is provided as the sum of ages $2-10+$ index. Fish older than age 9 were included in the age 10+ index².

| Year | 0-10+ | 2+ | Age 0 | Age 1 | Age 2 | Age 3 | Age 4 | Age 5 | Age 6 | Age 7 | Age 8 | Age 9 | Age 10+ |

Note: number of fish taken but not measured = one in 1984, one in 1988, two in 1990.

Table 5.25. Striped bass indices-at-age, 1984-2015.
Spring length data was converted to ages using the average of Hudson River and Chesapeake Bay von Bertalanffy parameters (Vic Crecco, pers comm). Indices-at-age were then determined by apportioning the spring indices (from Table 5.18) by the percentage of fish in each age.

|  |  | Spring |  |  |  |  |  |  |  |  |  |  |  |

Table 5.26. Summer flounder indices-at-age, 1984-2015.
Year and season specific age keys obtained from the NMFS spring and fall surveys were used to convert LISTS length frequencies to ages. Starting in 2000 LISTS ageing data ( 60 cm and over) were added to the age key to supplement the older age groups. In 2015, LISTS age data for smaller fish were also incorporated into the age key. Indices-at-age were determined for each season by apportioning the spring and fall overall indices (from Table 5.18 and Table 5.19) by the percentage of fish in each age.

note: 1984-1999 indices-at-age were run using a GT 60 cm group in the age key.

Table 5.27. Tautog indices-at-age, 1984-2015.
Year and season specific age keys obtained from the LISTS spring and fall surveys were used to convert LISTS length frequencies to ages. Indices-at-age were then determined for each season by apportioning the spring and fall overall indices (from Table 5.18 and Table 5.19) by the percentage of fish in each age, and then summing the spring and fall indices-at-age. The age 1$20+$ index is the sum of indices ages $1-20+$. The age $20+$ category includes 36 fish ranging from 20 to 30 years of age.

Job 5 Page 40

Table 5.28. Weakfish age 0 and age $1+$ indices of abundance, 1984-2015.
Using spring (May, June) and fall (September, October) length data, the geometric mean catch per tow was calculated for three groups of weakfish: fall age-0, spring - all fish age 1 and older (1+), and fall - all fish age 1 and older (1+). Weakfish less than 30 cm fork length in the fall were defined as age-0.

| Year | Fall |  | Fall |  | Spring |  |

Table 5.29. Winter flounder indices-at-age, 1984-2015.
The Long Island Sound Trawl Survey April and May catch and age data was used to calculate the geometric mean indices-at-age. An April-May age key was used to convert lengths to ages, and an overall April-May index (the ages 1-13 index in the table) was apportioned by the percentage of fish at age. The 4+ index is the sum of indices ages 4-13 and represents the abundance of winter flounder that are recruited to the fishery. The age-0 indices were obtained from the Estuarine Seine Survey (Job 8).

Note: 1984: April = 0 tows, May = 13 tows, and 19 tows in June used to increase sample size; 1985: April = 0 tows, May = 41 tows; 1986-1991, 1993-1995,
1997-2004, 2009, and 2012-2015: April = 40 tows, May = 40 tows; 1992 and 2006: April = 0 tows, May = 40; 1996: April = 17 tows, May = 63 tows; 2005: April = 35 tows, May = 45 tows; 2007: April = 35 tows, May = 45 tows; 2008: April = 36, and May = 44 tows; 2010: May = 38 tows, 2011 : April = 12 tows.

TABLES 5.30-5.66 LENGTH FREQUENCIES LISTS

Table 5.30. Alewife length frequencies, spring and fall, 1 cm intervals, 1989-2015.
From 1989-1990, lengths were recorded from the first three tows of each day; since 1991, lengths have been recorded from every tow.

| length | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 5.35. American lobster length frequencies-fall, male, 1 mm intervals, 1984-2015.
Lobsters were measured from each tow.

Table 5.36. Atlantic herring length frequencies, spring and fall, $\mathbf{1} \mathbf{~ c m ~ i n t e r v a l s , ~ 1 9 8 9 - 2 0 1 5 . ~}$
From 1989-2013, Atlantic herring lengths were recorded from the first three tows of each day; since 2014, lengths have been recorded from every tow.

Table 5.37. Atlantic menhaden length frequency, spring and fall, 1 cm intervals, 1996-2015.
Menhaden are scheduled to be measured from every tow. However, the following numbers of menhaden were not measured: 5 juveniles and 4 adults in 1996, and 7 adults in 1997.

| length | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Job 5 Page 53

Table 5.40. Blueback herring length frequencies, spring and fall, 1 cm intervals, 1989-2015.
From 1989-1990, lengths were recorded from the first three tows of each day; since 1991, lengths have been recorded from every tow.

Table 5.41. Bluefish length frequencies, spring, $\mathbf{1}$ cm intervals, 1984-2015.
Bluefish lengths were recorded from every tow.

Table 5.43. Butterfish length frequencies, 1 cm intervals, spring and fall, 1986-1990, 1992-2015.
Prior to 2014, length frequencies of butterfish were taken from the first three tows of each day; since 2014, lengths have been recorded from every tow.

Table 5.46. Fourspot flounder length frequencies, spring and fall, 2 cm intervals (midpoint given), 1989, 1990, 19962015.

Prior to 2014, Fourspot flounder lengths were recorded from the first three tows of each day; since 2014, lengths have been recorded from every tow.

Table 5.47. Hickory shad length frequencies, spring and fall, 1 cm intervals, 1991-2015.
Hickory shad were measured from every tow, with the exception of one fish in each of fall 1996, fall 1997, and fall 1998.

| Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 5.51. Long-finned squid length frequencies, fall, 1 cm intervals, 1986-1990, 1992-2015.
From 1986 - 1990, and 1992-2013, Length frequencies of squid taken from the first three tows of each day; since 2014, lengths have been recorded from every tow.

| $\frac{\text { length }}{0}$ | 1986 | 1987 0 | 1988 | 1989 | 1990 | 1992 | 1993 | 1994 | 1995 | 1996 0 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | $\underline{2008}$ | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 | 2015 |

Table 5.53. Scup fall length frequencies, 1 cm intervals, 1984-2015.
Lengths were recorded from every tow.

Table 5.57. Summer flounder length frequencies, fall, 2 cm intervals (midpoint given), 1984-2015.
All summer flounder taken in the Survey were measured, with the exception of two fish in 1985.

Table 5.60. Weakfish length frequencies, spring, 2 cm intervals (midpoint given), 1984-2015.
Weakfish were measured from every tow.

Table 5.61. Weakfish length frequencies, fall, 2 cm intervals (midpoint given), 1984-2015.
Weakfish were measured from every tow, with the exceptions of 968 juveniles in 1988 and 863 juveniles in 1989 that were not measured.

Table 5.62. Windowpane flounder length frequencies, spring, 1 cm intervals, 1989, 1990, 1994-2015.
Prior to 2014, lengths were recorded from the first three tows of each day; since 2014, lengths have been recorded from every tow.

Winter skate were scheduled to be measured from every tow. However, the following numbers of skate were not measured: 4 in 1995, 10 in 1996, and 2 in 1997.

FIGURES 5.1-5.19 LISTS

Figure 5.1. Trawl Survey site grid. Each sampling site is $1 \times 2 \mathrm{nmi}$ (nautical miles). A four-digit number identifies the site: the first two digits are the row numbers (corresponding to minutes of latitude) and the last two digits are the column numbers (corresponding to two nautical miles in length on the longitudinal axis). Examples: site 1428 near Guilford and 0028 near Mattituck. (Note: The sites in column 16 are approximately $2 x 1$ nmi. The grid was drawn on the Eastern and Western Long Island Sound 80,000:1 nautical charts, which overlap by the area in column 16.)

Figure 5.2. April 2015 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Samples collected from a different site than published in the "Notice to Fishermen" are noted in table below map.

Job 5 Page 87

Figure 5.7. Number of finfish species observed annually, 1984-2015. Note: there was no October sampling in 2006 and there was no June, September or October sampling in 2010. Average number of finfish species caught per year is 57.6 for the time-series. See Table 5.4 for details on number of tows completed each year.

Figure 5.8. Plots of abundance indices for: black sea bass, bluefish (total, age 0, and ages $1+$ ), butterfish, cunner, and dogfish (smooth and spiny).

Legend:

$$
\begin{aligned}
\square & =\text { count } / \text { tow } \\
\boldsymbol{\Delta} & =\mathrm{kg} / \text { tow } \\
---- & =\text { mean count } / \text { tow }
\end{aligned}
$$

Figure 5.9. Plots of abundance indices for: flounders (fourspot, summer, windowpane, winter, and winter ages $4+$ ) and hakes (red, silver, and spotted).

Legend:

$$
\begin{aligned}
\square & =\text { count } / \text { tow } \\
\boldsymbol{\Delta} & =\mathrm{kg} / \text { tow } \\
---- & =\text { mean count } / \text { tow }
\end{aligned}
$$

Figure 5.10. Plots of abundance indices for: herrings (alewife, Atlantic, and blueback), hogchoker, Northern kingfish, Atlantic menhaden, moonfish, and ocean pout.

Legend:

$$
\begin{aligned}

| ---: | :--- |
| $\boldsymbol{\square}$ | $=$ kg $/$ tow |
| ---- | $=$ mean count $/$ tow |

Figure 5.13 Plots of abundance indices for: striped bass, Atlantic sturgeon, tautog, and weakfish (all ages, age 0, and ages $1+$ ).

Legend:

| $\square$ | $=$ count $/$ tow |
| ---: | :--- |
| $\boldsymbol{\square}$ | $=\mathrm{kg} /$ tow |
| --- | $=$ mean count $/$ tow |

Figure 5.14. Plots of abundance and biomass indices for: crabs (lady, rock, and spider), horseshoe crab, American lobster, and long-finned squid.

Legend for bottom four graphs:

$$
\begin{aligned}
\square & =\text { count } / \text { tow } \\
\boldsymbol{\Delta} & =\mathrm{kg} / \text { tow } \\
---- & =\text { mean count } / \text { tow }
\end{aligned}
$$

Figure 5.15. Mean number of finfish species per sample, spring and fall, 1984-2015. This index measures the diversity of species supported within the Sound's various habitats.

Figure 5.16. Open water forage abundance, 1992-2015. The geometric mean is calculated as the aggregate sample biomass per tow of 14 of the most common forage species sampled in the survey. This index measures the available food base which supports both resident and migratory species. The average since 1992 is $13.85 \mathrm{~kg} / \mathrm{tow}$ (red line).

Figure 5.17. Geometric mean biomass of finfish and invertebrates per sample, spring and fall, 1992-2015. This index measures the diversity of species supported within the Sound's various habitats.

Figure 5.18: Percent of sampled winter flounder that were sexually mature by length group for female and male flounder captured in LISTS over five time periods, 1990-2013.

Figure 5.19. Trends in the number of cold temperate versus warm temperate species per sample captured in spring and fall LIS Trawl Surveys. See Appendix 2.5 for list of species included in analysis.

# THIS PAGE INTENTIONALLY LEFT BLANK 

## APPENDICES

LISTS

Appendix 5.1. List of finfish species identified by A Study of Marine Recreational Fisheries in Connecticut (F54R) and other CT DEP Marine Fisheries Division programs. LISTS has collected one hundred-nine (109) finfish species from 1984-2015. This appendix contains a list of 147 species identified (Bold type indicates new species) from all sampling programs conducted since 1984. Species are listed alphabetically by common name (AFS 2004). Sampling program abbreviations, survey time periods and gear type are as follows:

| Survey Abbreviation | Survey Description | Time Period | Gear Type |
| :---: | :---: | :---: | :---: |
| CTR | CT River Creel Survey | 1997-1998 | bus stop creel survey mainstem of CT River |
| EPA | cooperative sampling in western LIS with EPA | 1986-1990 | used LISTS net |
| ESS (F54R) | Estuarine Seine Survey | 1988 to present | 7.6 m ( 25 ft ) beach seine |
| IS (F54R) | Inshore Survey of Juvenile Winter Flounder | 1990-1994 | beam trawls (also a little data from 1995-1996) |
| ISS (F54R-starting 2008) | Inshore Seine Surveys in CT \& TH rivers | 1979 to present | $15.2 \mathrm{~m}(50 \mathrm{ft})$ bag seine set by boat |
| LISTS (F54R) | Long Island Sound Trawl Survey | 1984 to present | $14 \mathrm{~m}(50 \mathrm{ft})$ trawls with 2" codend mesh |
| MISC | misc sampling conducted on R/V Dempsey | various | various |
| NCA | "inshore" EPA NCA C2K sampling | 2000 | skiff trawls |
| NRRWS | sampling in western end of LIS, the "Narrows" | 2000-2007 | $14 \mathrm{~m}(50 \mathrm{ft}$ ) trawls with 2" codend mesh |
| SNFH (F54R) | Study of Nearshore Finfish Habitat | 1995-1996 | plankton net |
| SS (F54R) | Summer Survey | 1991-1993, 1996 | 14m (50 ft) trawls with codend liner in LIS |
| TN | Trap Net Survey | 1997-1998 | trap nets in rivers |

Appendix 5.4. cont. Total number and weight (kg) of finfish and invertebrates caught in LISTS in 2001.
Finfish species are in order of descending count. Invertebrate species are in order of descending weight (nc = not counted). Young-of-year bay anchovy, striped anchovy, and American sand lance and Atlantic herring are not quantified. Number of tows (sample size)=200.

## Finfish not ranked

anchovy spp, yoy
Atlantic herring, yoy
American sand lance (yoy)

Appendix 5.4. cont. Total number and weight (kg) of finfish and invertebrates caught in 2011.
Finfish species are in order of descending count. Invertebrate species are in order of descending weight (nc $=$ not counted). Young-of-year bay and striped anchovy are neither separated by species or quantified; young-of-year Atlantic herring and American sand lance are not quantified. Number of tows (sample size)=172.

Table 5.15. Total number and weight (kg) of finfish and invertebrates caught in 2014.
Finfish species are in order of descending count. Invertebrate species are in order of descending weight (nc = not counted). Young-of-year bay and striped anchovy are neither separated by species or quantified; young-of-year Atlantic herring and American sand lance are not quantified. Number of tows (sample size)=199.

Appendix 5.5: Endangered Species Interactions: One (1) Atlantic sturgeon (ATS) and one (1) Kemp’s ridley sea turtle (KST) were captured on two of the 200 tows completed in 2015. For Atlantic sturgeon, this yields a lower encounter rate ( $0.5 \%$ ) than the average for the LISTS time series of tows ( $2.3 \%$ ). This is the first Kemp’s ridley encounter for the survey. The Atlantic sturgeon tow occurred over sand bottom type in the 5-9m depth interval, while the Kemp's ridley occurred over transition bottom type in the $5-9 \mathrm{~m}$ depth interval. Both individuals were released alive and uninjured. Neither were scanned for a passive integrated transponder (PIT) due to a tag reader malfunction. Since the sturgeon could not be checked for a PIT, a genetic sample was not obtained. Both captures were reported to NMFS within 24 hours. Details for each species are provided below:

| Photo | Sample | Date | Site | Tow Start | Duration (min) | Species | Total Length (mm) | Fork Length (mm) | Weight (kg) | $\begin{gathered} \text { Left } \\ \text { Pec } \\ \text { T-bar } \end{gathered}$ | $\begin{aligned} & \text { Dorsal } \\ & \text { T-bar } \end{aligned}$ | PIT | Tissue Sample | Release time | Release lat ( N ) | Release Ion (W) |

Appendix 5.6: Cold and warm temperate species captured in LISTS. Thirty-three (33) species are included in the cold temperate group, while thirty-four (34) species are included in the warm temperate group. Cold temperate species are defined as being more abundant north of Cape Cod, MA than south of New York, behaviorally adapted to cold temperatures including subfreezing but prefers $\sim 3-15^{\circ} \mathrm{C}$, and spawns at lower end of temperature tolerance. Warm temperate species are defined as being more abundant south of New York than north of Cape Cod, MA, behaviorally avoids temperatures $<7-10^{\circ} \mathrm{C}$; prefers $\sim 11-22^{\circ} \mathrm{C}$, and spawns at higher end of temperature tolerance.

## JOB 6: STUDIES IN CONSERVATION ENGINEERING

## GOAL

Evaluate new technologies and methodologies for potential inclusion in the Long Island Sound Trawl Survey or other Surveys of this Project.

## OBJECTIVES

1) Characterize catch composition and selectivity patterns using different gear combinations for Connecticut's marine fishery-independent monitoring surveys. Particular emphasis will be placed on evaluating modern trawl net design/materials and doors combinations for potential use on the Long Island Sound Trawl Survey.
2) Evaluate impacts of gear changes on associated thirty-year time series data which is used in numerous coastal stock assessments, management decisions, essential fish habitat analysis and climate change studies.
3) Assess electronic data acquisition systems for fisheries research for potential benefits of modernizing the Long Island Sound Trawl Survey or other Surveys of this Project.
4) Assess new software applications to integrate the components of an onboard electronic data acquisition system with a computerized database for data collection and QA/QC for the Long Island Sound Trawl Survey or other Surveys of this Project.

## INTRODUCTION

Based on new information received after last year's report was completed, the Goal was modified and new Objectives were added. Work during this segment focused on Objective 3, however future segments may focus on other Objectives.

Initially, work for this Job was intended to evaluate a new type of door for the Long Island Sound Trawl Survey (LISTS) because the doors currently in use were well-worn and needed to be replaced, yet Survey staff had been unsuccessful in locating a new, affordable, vendor for the oldstyle doors for the past few years. Ultimately, it was discovered that another survey on the Atlantic Coast was using the same doors as LISTS, and that the cost to get new ones from their vendor was reasonable. Subsequently, the decision was made to stay with the old-style doors rather than risk affecting the consistency of LISTS's valuable long time-series by changing to a new type of door. Since there would be no change in the door or net configuration fished for the Survey, there would also be no need to conduct the comparison tows as originally proposed for this Job. Instead, a different type of new technology would be evaluated: an electronic data acquisition system for fisheries research to modernize LISTS data collection and data entry.

Long Island Sound Trawl Survey (LISTS) staff are proposing to upgrade the data collection processes that have been in place since the inception of the survey 32 years ago. Although paper and pencil for recording data on research vessels has worked well for LISTS for decades, a number
of similar fish surveys along the coast have been using electronic data acquisition hardware and software successfully for quite some time. Some surveys, notably the Northeast Federal bottom trawl surveys, have been mostly digital for over a decade now. Recent improvements in software and hardware are making a digital onboard system more realistic for the Long Island Sound Trawl Survey. Project staff are currently investigating the components that would be required to set-up a mostly wireless data collection system for the 50’ R/V John Dempsey that would likely include an onboard computer network of electronic scales, measuring boards and mobile devices. Although electronic fisheries data acquisition systems can be expensive, they typically improve the accuracy and efficiency of fisheries independent surveys by streamlining sampling procedures and decreasing transcription errors at sea, as well as decreasing or eliminating data entry and key punch errors and QA/QC procedures in the office. All of which results in better quality data being available more quickly for fisheries management decisions.

An electronic measuring station on the NEAMAP trawl survey.

## METHODS

Survey staff from other trawl surveys conducted along the Atlantic Coast were canvassed for information about their electronic data acquisition systems (MassDMF, NEAMAP, NMFS) and numerous vendors were contacted for detailed specifications of the available components. Repeatedly, two main aspects of the Long Island Sound Trawl Survey's needs made it difficult for LISTS to mimic the setup on the other Surveys. The first issue is the smaller vessel with much less deck space available to LISTS compared to other surveys. Other surveys have enough deck space to accommodate metal tables with windshields affixed to the deck while still having deck
space to spill the codend and sort the catch. For LISTS, the sorting table becomes the measuring table once sorting is completed, so measuring workstations cannot be left set up on deck in between tows. Thus, any components for measuring stations need to be easily set up and taken down multiple times each day.

The second main issue for LISTS is that all of the Long Island Sound Trawl Survey gear has to be removed from the research vessel so gear for the Long Island Sound Ambient Water Quality Monitoring Program (Job 10) can be loaded. This means that, even if measuring stations could be affixed to the deck for the trawl survey, they would need to be removed for the water survey. This unloading/loading of gear occurs at least ten times each year and frequently there is only a few hours available to complete the transition.

The other large-scale trawl surveys that were canvassed about their electronic data acquisition systems were primarily set up with hardwired components on semi-permanent workstations. LISTS' need to be able to easily and quickly set up and remove components for electronic measuring stations means components will need to be wireless and/or Bluetooth capable as much as possible.

## RESULTS

After evaluating numerous options for the components of an electronic data acquisition system for fisheries research, the following specifications describe the components being considered for the LISTS' system:

- Xplore Technologies DMSR XC6 Series Tablets -
http://www.xploretech.com/products/xc6-dmsr-rugged-sunlight-readable-windows-tablet -XC6-Dual Mode Sunlight Readable, Intel i5-VGA-Standard-Windows 7-64bit-256GB SSD (2 x 128GB)-4GB-`No WWAN-North America WiFi-Bluetooth\Camera-5 Day TAT-5yr Extended P.N. 01-35000-76F4E-00T05-000. Needs latest Office software; 10cell ( 80.75 watt hour) long-lasting, Li-Ion Battery; 1 year limited warranty; Part Number: 11-01022, Dual Bay Battery Charger; one conditioning bay. Power cord not included, C13 Type power cord for NA sold separately. 1 year limited warranty. Part Number: 1111013. Passive 3-D Float system dock and mounts for each location (provided by Xplore and Ram)
- Scantrol measuring boards (2@50cm,1@100cm) all wired USB powered through tablet FM-50USB, FM-100USB http://www.scantrol.com/wp-content/uploads/2013/01/FishMeter-brochure_interactive1.pdf
- Bigfin measuring board (1@850 cm) wireless and Bluetooth https://squareup.com/market/bigfinscientific
- Marel weighing scales - $\mathbf{M}$ series 1100
https://marel.com/files/products/brochures/marine-scales-brochure_low.pdf?ind=fish converts and captures output directly into FEED software
- I-key or Wetkeys keyboards (6) $\mathbf{1 0 0 \%}$ waterproof DU-5K-NI Nonincendive Keyboard with HulaPoint II - http://www.ikey.com/product/du-5kni/\#sthash.UPFxbsgT.dpuf must have VESA Mounting holes for Ram bracket off of passive dock. SK-102-M
- Laptop Serv \& Phys. Laptop - physical data from EXO2 and Helm feed (GPS NEMA 183) on one laptop (currently being used on Dempsey) FEED may be able to read all this data into database. Bluetooth to this laptop from EXO2 and convert NEMA using current serial to USB adaptor. Server Laptop will house FEED database. However if problems occur with network/server each laptop will have an independent separate FEED application that records data and then you would transfer by flash drive. With normal operation each tablets FEED application will write to the database on the Laptop server. This database server will only have that duty and, as with all the tablets, only ever be connected to the network. At some point we will work out downloads (say from the dock) to our network at marine HQ but for now we will use flash drives to backup each sampling day.
- Wireless Router
- YSI EXO WQ Data sonde
- Zebra GK420t Printer Zebra Advanced Printer G-Series GK420t - label printer monochrome - direct thermal / thermal transfer. Mfg. Part: GK42-102510-000
- APC Back-UPC ES 750VA (2 total) APC Back-UPS ES 750VA UPS Mfg. Part: BE750G
- NAS for mirroring (backup) of hard drive
- FEED Software

Schematic of how the components of an electronic data acquisition system might be situated on the R/V John Dempsey.

Naturally, the system configuration will need to be refined as components are gradually purchased and set up for use on the Survey in future segments of this Job. A customized software application will also need to be designed to integrate all of the new electronic components and incorporate standardized LISTS protocols for data collected from each sample, data storage and quality assurance.

## MODIFICATIONS

Due to the nature of evaluating new technologies, it is not known ahead of time which ideas will be implemented. Therefore, the specific Objectives of this Job are likely to change over time. With that in mind, in the next segment of the Project, we expect to continue work to evaluate new hardware and software in the hopes of implementing an electronic data acquisition system on the LIS Trawl Survey. Future segments of the Project may be used to investigate other new technologies or methodologies that have potential benefits for the LIS Trawl Survey or other Surveys in this Project.

## Job 7: ALOSINE SURVEY INACTIVE

Job 7 was not active during the 2015-2016 grant period because the work was transferred to another source of funds. However, work on this job may be transferred back to this program funding before the end of the 2016-2017 grant period.

## Beach seining with 25’ bag seine.

## JOB 8: ESTUARINE SEINE SURVEY

GOAL
To monitor the abundance and size composition of near-shore young-of-year and forage fish resources, with physical habitat parameters, in order to evaluate the effects of fishing and environmental conditions on the distribution and abundance of marine resources in Long Island Sound.

## OBJECTIVES

1) Provide an annual index of recruitment for winter flounder (Age0, 1+), all finfsh species taken, and all crab species.
2) Provide an annual total count for all finfish taken.
3) Provide an index for shallow subtidal forage species abundance.

## METHODS

Eight sites (Figure 8.1) are sampled during September using an eight-meter ( 25 ft .) bag seine with 6.4 mm ( 0.25 in .) bar mesh. Area swept is standardized to 4.6 m ( 15 ft .), width by means of a taut spreader rope and a 30 m ( 98 ft .), measured distance, parallel to, or at a $45^{\circ}$ angle to the shoreline, against the current or tide if present. At each site, six seine hauls are taken within two hours before and after low slack tide during daylight hours. Sites in Groton, Waterford, Old Lyme, Clinton, New Haven, Bridgeport and Greenwich have been sampled since 1988. The Milford site was added in 1990. In addition to September sampling, six of the original seven sites were sampled in June, July, and August 2013-2015 to compare with samples taken in these months in 1988-1990. Sampling methods were the same as described above.

Finfish, crabs, and other invertebrates taken in each sample are identified to species or lowest practical taxon (full listing given in Appendix 8.1, 8.2) and counted. One exception is inland silverside, which are not separated from Atlantic silverside because they are rare and difficult to identify. Qualitative counts were used for menhaden when abundant ( $\mathrm{n}>1000$ ) to minimize discard mortality. Winter flounder are measured to total length (mm), and classified as young-of-year (YOY) if less than 12 cm and age $1+$ if 12 cm or larger. The age of flounder near this size was verified in 1990-1992 by examination of the sagittal otolith. Physical data recorded at each seine location included water temperature and salinity at one-meter depth. The geometric (retransformed natural log) mean catch per standard haul is calculated for total finfish catch and individually for the 22 most abundant species, with separate indices for young-of-year (YOY) and winter flounder age 1 and older. Winter flounder YOY catch is also reported for each site. Confidence intervals (95\%) for each geometric mean are retransformations of the corresponding log intervals. Frequency of occurrence is given as a percentage of all samples taken each year.

Diversity in the catch, or species richness, was computed for finfish species captured in the

Survey over the time series. Species were divided into three groups based on their temperature preferences and seasonal spawning habits as documented in the literature. Criteria used to assign species into a cold temperate group, warm temperate group, or subtropical group are listed in Job 5.

## RESULTS

A total of 48 seine hauls were taken in 2015 at eight sites, yielding a total catch of 19,070 fish of 27 species and 16,966 invertebrates of 11 species. Geometric mean catch of all finfish ( 330 fish/haul) was the highest in the 28 year time series (Figure 8.2), and more than double the time series median of 135 fish/haul. Although total catch has varied considerably year to year, the increasing trend is significant ( $\mathrm{df}=27, \mathrm{r}^{2}=0.11, \mathrm{p}=0.05$ ). Dominant species contributing to this increase include young-of-year (YOY) black sea bass, tautog, scup (porgy), northern kingfish, striped searobin, and menhaden.

Geometric means were calculated for 22 species commonly captured since the survey began in 1988 (Table 8.1). The most frequently caught species was Atlantic silverside, which occurred in all samples, followed by black sea bass, striped killifish, tautog, snapper bluefish and northern pipefish (Table 8.2). This rank order has changed from previous years, with a notable decrease in winter flounder YOY (Figure 8.3) grubby, and windowpane flounder.

Scup, snapper bluefish, black sea bass and northern kingfish occurrence and abundance increased well above the 28 year time series average in 2015, increasing to record high abundance for the time series (Tables 8.1 and 8.2). Occurrence of striped searobin and inshore lizardfish also ranked high in the time series. Windowpane flounder was again absent in 2015 after re-occurring at low abundance in 2011 and 2014, but absent in 200910 and 2012-13 (Table 8.1).

## Relative Abundance of Juvenile Winter Flounder and Tautog

The 2015 index of YOY winter flounder ( 0.6 fish/haul) continued a 4-year trend of modest increase, but still ranked fourth lowest out of the 28 annual indices (Table 8.3, Figure 8.3). The time series has a significant negative trend ( $\mathrm{r}^{2}=0.34, \mathrm{p}<0.001$ ), and indicates that a relatively strong year class has not been produced since 1996 (Table 8.1, Figure 8.3). As in previous years, highest abundance was seen at eastern sites (Groton, Waterford, Old Lyme, Clinton) and Greenwich, with all but Old Lyme increasing from 2014 (Table 8.3). Abundance at the New Haven site continued to decline from previous high values, with the 2015 index at the same low value as the neighboring Milford site. No winter flounder were captured at the Bridgeport site in 2015, as was seen in 2012-13. Mean length of YOY winter flounder captured at all sites shows no trend over the 28-year time series, ranging from 47.3 to 71.1 mm .

The 2015 index of YOY tautog ( 4.8 fish/haul) was the highest abundance in the time series (Table 8.1, Figure 8.4), significantly higher than the series average of 1.0 tautog /haul.

Overall, the time series has a significant increasing trend $\left(r^{2}=0.27, p=0.003\right)$. Relatively abundant year classes have been produced in 1998-99, 2002-04, 2007-08, 2012 and 201415. The frequency of occurrence of this species has also increased over the time series (Figure 8.4) indicating that juvenile production and survival is improving in several areas of the Sound.

## Presence of Other Important Recreational Finfish

YOY scup and black seabass are recent additions to the seine survey (Table 8.1, Figure 8.5). Scup occurred in 1999 but the highest relative abundance has been in the last ten years of the time series. In 2014 and 2015, the species was present in record numbers, reflecting excellent recruitment and survival. YOY black sea bass first appeared in 1991 and every year since 1997, reaching their record highest abundance in 2015. Juvenile striped bass first occurred in the survey in 1999 with one individual captured. In 2003, six more YOY striped bass were taken (Table 8.4). One large individual (369mm) was captured in 2008. YOY summer flounder also have occurred more recently in greater numbers (Table 8.4). Snapper bluefish occurred in 21 out of 28 years of the time series, reaching peak abundance in 1999 and 2014-15 (Table 8.4). Other species that were at their highest abundance in 2015 catches were northern searobin and American eel Table 8.5).

## Relative Abundance of Forage Species

Seine survey catches are numerically dominated by forage species, defined here as shortlived, highly fecund species that spend the majority of their life cycle inshore where they are common food items for piscivorous fish. An index of forage fish abundance was generated using the catch of four of the most common forage species caught: Atlantic silverside, striped killifish, mummichog, and sheepshead minnow (Figure 8.6). The index for 2015 was the second highest in the 28 year time series. Although numerically driven by the abundance of silverside, three of the four forage fish species increased in abundance and occurrence in 2015; all but sheepshead minnow showed a large increase in abundance. Atlantic silverside abundance increased in 2015 to the highest value in the time series (115 fish/haul, Table 8.1). The mean catch of both Fundulus species (mummichog and striped killifish) increased significantly ( $\mathrm{r}^{2} 0.11-0.28, \mathrm{p}<0.05$ ) over the 28 year time series. A decrease in these species' abundance in 2012-13 reversed a five-year trend of increasing abundance from 2007-2011. In 2014-15 striped killifish increased substantially in abundance and frequency of occurrence (14.5-17.1 fish/tow, $88 \%$ occurrence), abundance well above the series mean of 10.3 fish/haul. In 2015, mummichog abundance (5.3 fish/haul) was also well above the long-term average of 2.5 fish/haul. Over the 28 year time series, the forage index has shown a 5-7 year cyclical pattern, common for short-lived forage species, with no significant trend ( $\left(r^{2} 0.06, p=0.11\right.$, Figure 8.6).

## Relative Abundance of Invertebrate Species

A total of 16,966 invertebrates of 11 species were captured in 2015 (Table 8.6, Appendix 8.2). Six crab species were present in the seine hauls, along with two shrimp species, one gastropod and bivalve. Mud snail, sand shrimp, shore shrimp, green crab, and hermit crab were the most abundant and at greater than $50 \%$ occurrence (Table 8.3).

Blue crabs were captured at the Clinton and Waterford sites only, and continued at relatively low abundance in 2015 ( $\mathrm{n}=18$ crabs) down from a time series high in 2009 ( $\mathrm{n}=333$ crabs). The Asian shore crab re-appeared in 2015, with only one captured at the Greenwich site. The shore shrimp increased substantially in abundance in 2014-15 from previous years, while sand shrimp decreased significantly (Table 8.3). Spider crab abundance has also increased nearly ten-fold since 2011 compared to earlier years, with the highest catch in 2015.

## Finfish Species Richness

Over the 28-year time series, the mean number of cold temperate species captured per seine haul (Figure 8.7, Table 8.7) was less than three with a negative trend ( $\mathrm{r}^{2}=0.15, \mathrm{p}=0.025$ ). In contrast, the mean number of warm temperate species increased significantly $\left(\mathrm{r}^{2}=0.59\right.$, $\mathrm{p}<0.001$ ) from about three to more than seven over the time series.

## Comparison of 2013-2015 Summer Sampling with 1988-1990

A total of 396 seine hauls were taken monthly, June - September, 2013-2015 at six of the eight seine sites (Groton, Waterford, Clinton, New Haven, Bridgeport, Greenwich, see Figure 8.1) that were unchanged physically since similar samples ( $\mathrm{N}=415$ ) were taken in 1988-1990 in the same months. Six hauls were taken at each site except for Greenwich where only three haul locations (Pelican Island) were comparable during both time periods.

Catch of all finfish species in June-September 2013-2015 resulted in a geometric mean of 22.6-227.4 fish/haul, which compared to 38.6.-159.1 in 1988-1990 (Figure 8.8). Lowest abundance was in June and peak abundance in August and September. This seasonal progression reflects resident and migrant species recruiting to the mesh size of the sampling gear and/or moving onto the nursery grounds. Standard errors for 2013-2015 monthly means (CV range of 13-28\%) make the recent mean values statistically indistinguishable from 1988-1990 monthly means (CV range of 15-29\%). However, a steady rise in species number, from 3.1 species/haul to 8.5 species/haul (Figure 8.8), was recorded by month in 2013-2015 that was not seen in 1988-1990 (range 4.1 to 5.2 species/haul).

In contrast to the seasonal increase in abundance seen in total finfish from June through September, winter flounder young-of-year (YOY) abundance was highest in June and declined over the summer during both time periods (Figure 8.9). Although abundance in June was similar for both time periods, attrition from July-September in 2013-2015 was more than five times greater (slope $=-0.66, r^{2}=0.99$ ) compared to the same months in 19881990 (slope $=-0.11, \mathrm{r}^{2}=0.98$ ). This increasing decline in abundance over the summer months reduced moderate June abundance to the extremely low abundance recorded in September 2013-2015.

The average size of YOY winter flounder captured in June 2013-2015 (mean=39.8mm, $\mathrm{SE}=5.9$ ) was smaller than those captured in June 1988-1990 (mean=43.7mm, $\mathrm{SE}=5.7$ ), a $9 \%$ decline but not statistically significant due to the large variance in the data. Average size of juveniles captured in September in the later years were also smaller on average than in the earlier period ( $57.2 \mathrm{~mm}, \mathrm{SE}=6.3$ versus mean $60.6 \mathrm{~mm}, \mathrm{SE}=4.0$, respectively) but again the two data sets are not statistically distinguishable.

Tautog YOY, captured principally in the Waterford, Clinton, and New Haven sites, showed the opposite pattern from winter flounder YOY. Numbers increased dramatically in August and September 2013-2015 (Figure 8.10), while 1988-1990 sampling resulted in low catches in all months.

Seasonal comparison of forage species (principally Atlantic silversides, with mummichog, striped killifish, and sheepshead minnow included) between the two time periods showed no significant difference in abundance (1988-1990: geometric mean=31.2, $\mathrm{SE}=1.14$; 20132015: geometric mean=27.4, $\mathrm{SE}=1.15$ ). A small change in the seasonal pattern of abundance was seen: 1988-1990 data followed a sigmoid seasonal pattern compared to a more linear monthly increase seen in 2013-2015 (Figure 8.11).

Although water temperature plays an important role in YOY growth and abundance, little change in mean water temperature at these shallow beach sites was recorded between the two time periods. In the later period, lower values occurred in June (mean $1988-90=21.2^{\circ} \mathrm{C}$, $\mathrm{SD}=2.7$; mean 2013-15 $=20.5^{\circ} \mathrm{C}, \mathrm{SD}=4.4$ ) but similar values were recorded in September (mean $1988-90=21.6^{\circ} \mathrm{C}, \mathrm{SD}=2.1$; mean $2013-15=21.8^{\circ} \mathrm{C}, \mathrm{SD}=3.6$ ). Mean September temperature at these six sites shows no significant trend over the entire 28 year time series (Figure 8.12). Similarly, September salinity at these sites has varied widely and shows no significant trend over the time series (Figure 8.12).

## MODIFICATIONS

Seasonal sampling June-August was planned for 2013-2015 only and will be discontinued in 2016.

Table 8.1: Geometric mean catch of finfish species commonly taken in seine samples, 1988-2015. See Appendix 8.1 for complete taxonomic names.

## JOB 9: Volunteer Estuarine Fisheries Database

## GOAL

Identify estuarine near-shore waters critical to the production and growth of recreationally important finfish for the purpose of protecting and enhancing these populations in shallow water habitats and promote citizens' greater understanding and appreciation of local marine resources through participation in local volunteer survey projects.

## OBJECTIVES

1) Provide reliable indices of relative abundance for finfish and key water quality measurements by standardizing samples taken in Connecticut near-shore waters by local volunteers.
2) Document the occurrence of uncommon or rare species and their distribution by habitat type in order to determine their vulnerability to local extinction due to human activities and/or climate change.
3) Provide embayment-specific size and/or growth estimates for recreationally important species helpful to immediate and long-term local and regional assessments.
4) Develop and maintain a state-wide fisheries database of all volunteer survey programs in order to maximize their usefulness to all citizen groups, educational programs, municipalities, statewide regulatory programs and interstate management plans.

## INTRODUCTION

Several citizens’ groups formed in response to CT DEEP educational programs, as well as to address local environmental issues, have spent thousands of volunteer hours gathering fisheries abundance data and accompanying water quality information. This job was developed as a mechanism for establishing a flexible data framework where volunteer datasets can be collated, standardized, and accessed. This database should provide data useful for protecting the state's near-shore estuarine ecosystem which is particularly vulnerable to physical flux and alternation or degradation due to human activities.

## METHODS

Data were obtained from citizen groups that have gathered fisheries abundance and water quality data for more than a decade. Based on interviews with the groups' leaders, these data were collated into the Volunteer Estuarine Fisheries Database and synthetic summaries were made for purposes of comparison. Data summarized in this report are in addition to earlier datasets provided by Harbor Watch, Cedar Island Marina Laboratory, and Project Oceanology which were presented in last year's report.

For each program, a matrix was generated in Excel or Access software documenting the date, location, and quantity of each species captured in their sampled area by gear type. The total number of each finfish species was computed as a percentage of the total finfish captured by year. Additionally, relative abundance of finfish grouped by thermal guild (Howell and Auster 2012) as
well as total species number was computed for each study area as a generalized measure of embayment health.

## Harbor Watch Norwalk Harbor Survey

Harbor Watch, a Program sponsored by Earth Place Nature Center in Westport CT, has run a beam trawl survey in the Norwalk River since 1990. The program was initiated under the guidance of Richard Harris, Program Director, and CT DEEP Marine Fisheries Division staff, and continued in 2015 under Program Director Sarah Crosby. The sampling program divides the saline portion of the river into 20 fishable grids which overlap previously established water quality sampling stations (Figure 9.1). Benthic finfish and invertebrates are captured using a one-meter beam trawl ( 0.63 cm mesh net) towed for 5 minutes within one of the sample grids (Harris et al. 2014). Samples are made at least weekly at grids representing upper, middle, and lower reaches of the river. Sampling is accomplished with the help of students from Wilton High School.

## Maritime Aquarium Outer Norwalk Channel Survey

Maritime Aquarium staff have run 'marine life study cruises' for the public since 1990. Sampling cruises are conducted at least once per week from April through October, with one tow taken on each cruise in Norwalk and Sheffield Harbors. Sampling is constrained by boat traffic, channel configuration, and submerged debris (Figure 9.2). Marine organisms are collected using an otter trawl deployed on the north side of the navigational channel near Tavern Island (approx. $41^{\circ} 03.58$ ’ by $73^{\circ} 25.049^{\prime}$ ) and towed parallel to the channel in a westerly direction for approximately 20 minutes (Schneider and Schneirlein 2010). Catch data are recorded on standardized field sheets along with the location of sampling sites and weather conditions.

## Coast Guard Academy Thames River Survey

The academic curriculum of the US Coast Guard Academy has included biological sampling of the Thames River since the 1970s. Samples are taken in the Thames River from the Gold Star Bridge upriver to the Naval Submarine Base (Figure 9.3). Shallow ( $5-10 \mathrm{~m}$ depth) and channel (12-15m depth) tows are made one day per week from August to October with a 9.15 m flat trawl net (\# 15 twine, 5.10 cm stretch mesh, \#21 twine codend with 1.27 cm mesh and 0.95 cm liner; Mrakovcich, personal communication). The same gear and manual deployment technique has been used over the years, however the vessel changed in 2013. Tow duration was 10 minutes in 19742006 and changed to the equivalent 0.5 km in 2007-2015. Seine samples were taken in front of the beach adjacent to Eagle Pier at the Coast Guard Academy during the month of September (Mrakovcich, personal communication). Hauls are made at low tide using a $15 \mathrm{~m} \times 1.8 \mathrm{~m}$ seine net ( 0.6 cm square mesh with $1.8 \times 1.8 \times 1.8 \mathrm{~m}$ center bag).

## RESULTS

## Harbor Watch Norwalk Harbor Survey

From 1990-1994, the Harbor Watch program documented an abundance and high diversity of benthic fish (Figure 9.4). The largest concentrations of the target species, juvenile winter flounder, were captured from the I-95 Bridge south to the Maritime Center (grids A-D, Figure 9.1, Harris et al. 2014). From 1995-2005 comparable surveys were not performed due to necessary boat repairs and sampling outside Norwalk Harbor. Extensive dredging began in the upper harbor in 20052006. Limited sampling occurred in 2007 and resumed to a full program in 2008. The outer harbor
was dredged in 2010, but did not hinder sampling in the harbor proper. Beam trawl sampling captured 5-15 finfish species annually for years with comparable effort in June through October (Table 9.1). The lowest diversity and catch rate were reported in 2010, with a modest increase reported in 2015 when 499 fish were caught of 17 species. In 2015, winter flounder were captured in 18 of the 19 grids sampled and their number/tow were the highest recorded since 2005. Flounder were most abundant in the lower harbor (Box L, Figure 9.1, Crosby et al. 2015), a distribution that differed from the early 1990s when they were most abundant in the upper harbor. Winter flounder juveniles were the most abundant species followed by northern searobin and black seabass. When species are grouped by thermal guild (Appendix 9.1) it appears that warm temperate species have become more common in recent years (Figure 9.5).

Bottom water temperatures taken weekly at six stations in the Norwalk River beginning in 1987 (Figure 9.1) show a clear warming trend for years with complete sampling during summer, JulySeptember (Figure 9.6). Warming was greatest in the upper river (Stations 1 and 1a), and all stations combined show a positive slope of approximately $1.5^{0} \mathrm{C}\left(2.7^{0} \mathrm{~F}\right)$ over the time period.

## Maritime Aquarium OuterNorwalk Channel Survey

Aquarium staff have completed 98-181 otter trawl tows annually since 1993 with the exception of 1998 (Table 9.2, Figure 9.7). Mean catch declined from 19.7 fish/tow to less than 7 fish/tow through the 1990s and 2000s, but increased recently, exceeding 20 fish/tow in three of the last five years. Total species caught varied from 14-26 but show no trend over the time series. Several species of flounder, scup, and searobins have dominated the catch. As was seen in the Harbor Watch dataset above, when species are grouped by thermal guild (Appendix 9.2) it appears that warm temperate species have become more abundant in recent years: Collectively, warm temperate fish increased from $35 \%$ of the catch in 1993-1997 to 73\% of the catch in 2006-2015 (Figure 9.8).

## Coast Guard Academy Thames River Survey

The Academy marine science class surveys of the Thames River are documented beginning in 1974 (Table 9.3). Annual surveys varied from 4-18 otter trawl tows and 4-12 beach seine hauls. Finfish were captured in all samples by both gears (i.e., 100\% positive tows). Mean catch in trawl samples varied from 2.9-12.0 fish/tow without trend (Figure 9.9) while total species captured ranged from 7-32 annually with a slight increase in recent years. Windowpane and winter flounder dominated the catch in the beginning of the time series, but were replaced by summer flounder, scup, and butterfish in later years. When species are grouped by thermal guild (Figure 9.10, Appendix 9.3), catch showed a substantial increase in the percentage of warm temperate species and declining percentage of cold temperate species. Trawl samples also caught subtropical species in greater frequency beginning in 2003. Bottom water temperatures, measured late August to early October, showed a modest increase only recently with no significant trend (Figure 9.11).

Mean catch in seine samples varied from 1.1-10.0 fish/haul without trend (Table 9.3, Figure 9.12). Total species captured ranged from 9-28 annually, also without trend. However, catch in the beginning of the time series was dominated by killifish, windowpane and winter flounder young-of-year while recent catches were principally menhaden and tautog young-of-year. Guild grouping of the species captured by beach seine also showed an increase in the percentage of the warm temperate group, most notably demersal and pelagic species, with a decline in the percentage of epibenthic species of both guilds (Figure 9.13, Appendix 9.4).

## MODIFICATIONS

No modifications are expected.

Appendix 9.3: Finfish species occurrence in the Coast Guard Academy Thames River otter trawl samples, August-October, 19742015. Seven thermal guilds were present: cold temperate-demersal (CD), cold-temperate-epibenthic (CE), cold temperate-pelagic (CP), warm temperate-demersal (WD), warm temperate-epibenthic (WE), warm temperate-pelagic (WP), and subtropic pelagic (SP).

# 2015 Long Island Sound Hypoxia Season Review 

## MONITORING LONG ISLAND SOUND 2015

## Program Overview

Since 1991, the Connecticut Department of Energy \& Environmental Protection (CT DEEP, formerly the Department of Environmental Protection, (CTDEP)) has conducted an intensive year-round water quality monitoring program on Long Island Sound (LIS). Water quality is monitored at up to forty-eight (48) sites by staff aboard the Department's Research Vessel John Dempsey.

R/V John Dempsey

Data from the surveys are used to quantify and identify annual trends and differences in water quality parameters relevant to hypoxia (low dissolved oxygen), especially nutrients, temperature, and chlorophyll. These data are also used to evaluate the effectiveness of the management program to reduce nitrogen concentrations. During the summer (June -September) CT DEEP conducts additional summer hypoxia surveys at bi-weekly intervals to better define the areal extent and duration of hypoxia.

## CT DEEP Methods

Dissolved oxygen, temperature, pH , and salinity data are collected in situ (on site in the water column) using an electronic instrument called a Conductivity Temperature Depth recorder (CTD) that takes measurements from the surface to the bottom of the water column. The CTD, a SeaBird model SBE-19 SeaCat Profiler equipped with auxiliary dissolved oxygen, photosynthetically-active radiation (PAR) and pH sensors, is attached to a Rosette Sampler and lowered through the water column at a rate of approximately 0.2 meters per second and measurements are recorded every 0.5 seconds. In
 situ data are reviewed in real-time.

Water samples are collected using Niskin water sampling bottles that are attached to the Rosette Sampler. The Rosette is lowered off the stern of the Dempsey and the bottles are triggered remotely to take a water sample at any depth. Parameters for which surface and bottom waters are tested include dissolved silica, particulate silica, particulate carbon, dissolved organic carbon, dissolved nitrogen, particulate nitrogen, ammonia, nitrate + nitrite, particulate phosphorus, total dissolved phosphorus, orthophosphate, chlorophyll $a$, and total suspended solids.

Samples are filtered aboard the mini laboratory and preserved for later analyses at the Center for Environmental Science and Engineering at the University of Connecticut. From October to May, in situ data and nutrient samples are collected once a month from 17 sites. Bi-weekly hypoxia surveys start in mid-June and end in September with up to 48 stations being sampled during each survey for in situ parameters.

Since 2002, CT DEEP has collected zooplankton samples from six stations and phytoplankton from ten stations across Long Island Sound. The samples are sent to researchers at the University of Connecticut who identify species composition, abundance, community structure, and spatial and temporal distribution throughout the Sound.

## IEC

The Interstate Environmental Commission (IEC) is a tri-state water and air pollution control agency. Established in 1936 the IEC serves the States of New York, New Jersey, and Connecticut (www.iec-nynjct.org). The IEC's area of jurisdiction runs west from New Haven, CT and Port Jefferson, NY on Long Island Sound.

IEC has conducted monitoring in the far western LIS and the Upper East River since 1991. IEC collects in situ data from 22
 stations between June and September. In situ parameters include pH , temperature, salinity, water clarity (Secchi disk depth) and dissolved oxygen. More information about the program can be found on the IEC website under the Publications menu http://www.iec-nynjct.org/publications.htm.

Provisional IEC dissolved oxygen data collected during 2015 have been used to create hypoxia map interpolations in the far western Sound and appear on pages 13-22 adjacent to CTDEEP hypoxia maps. These maps are for illustrative purposes only.

## LISICOS

The Long Island Sound Integrated Coastal Observing System (LISICOS) was established in 2003 as a component of a regional/national ocean observing system. The system was conceptualized as part of a water quality monitoring program that combined the traditional ship-based point sampling surveys with continuous, real-time sampling stations. Funding for the program was first provided through the Environmental Protection Agency EMPACT grant program and is now provided by the National Oceanic and Atmospheric Administration.

The initial goal was to develop "a capability to observe and understand the LIS ecosystem and predict its response to natural and anthropogenic changes".

LISICOS monitors water quality parameters (e.g., salinity, temperature, dissolved oxygen, surface waves, photosynthetically available radiation, chlorophyll) and meteorological parameters (e.g., wind speed, direction, barometric pressure, wave height) at up to eight stations across the Sound. Sensors are attached to a moored buoy at various depths (surface, mid, bottom). Data are transmitted every 15 minutes in real-time via satellite (telemetered) where they are stored in a database and uploaded to the internet. The system is maintained by the University of Connecticut.

This report presents a summary of the 2015 in situ data collected by CT DEEP. Data from LISICOS and IEC are presented with permission for informational purposes.

The CT DEEP and IEC LIS Water Quality Monitoring Programs are synoptic in nature and are intended to characterize water quality conditions at one moment in time over a broad area (the entire Sound). Water column profile data provided by the programs are useful for future determinations of volume of hypoxic waters. Both programs support long term monitoring databases designed to detect changes in hypoxia due to changing conditions (i.e. management actions, climate change, productivity). The CT DEEP program also provides nutrient and biological data not available from fixed station buoy applications.

The LISICOS water quality sensors are attached to fixed locations and provide a holistic view of the conditions over a more detailed span of time (i.e., data measured every 15 minutes from one station as opposed to every two weeks). The LISICOS continuously recording buoys have shown instances where vertical mixing within the water column raises the DO concentrations above the hypoxic thresholds for extended periods of time (e.g., days). These episodic conditions are not captured by CT DEEP or IEC surveys which occur bi-monthly during the hypoxic season.

As such CT DEEP and IEC data provide a snapshot of hypoxic conditions at one time while the LISICOS data provide a continuous measurement of hypoxia at specific buoy locations. Together these monitoring programs are better able to characterize the extent and duration of hypoxia across LIS. Both types of data contribute to a better understanding of hypoxia in LIS.

## What is Hypoxia?

The term "hypoxia" means low dissolved oxygen ("DO") concentrations in the water. Marine organisms need oxygen to live, and low concentrations, depending on the duration and the size of the area affected, can have serious consequences for a marine ecosystem. As defined by the Long Island Sound Study, hypoxia exists when DO drops below a concentration of 3 milligrams per liter ( $\mathrm{mg} / \mathrm{L}$ ), although ongoing national research suggests that there may be adverse affects to organisms even above this level, depending upon the length of exposure. In 2011,
 Connecticut adopted revised water quality criteria for dissolved oxygen. These criteria, designed to protect the state's waters from degradation, define hypoxia as DO concentrations below $3.0 \mathrm{mg} / \mathrm{L}$. Low oxygen levels can occur naturally in estuaries during the summer, when calm weather conditions prevent the mixing of the water column that replenishes bottom water oxygen during the rest of the year. However, studies of the limited historical data base for the Sound suggest that summer oxygen depletion in Western Long Island Sound has grown worse since the 1950s.

## How Does Low Oxygen Impact the Sound?

Each summer low oxygen levels render hundreds of square miles of bottom water unhealthy for aquatic life. DO levels follow seasonal patterns with a decrease in bottom water DO over the course of the summer. Hypoxic conditions during the summer are mainly confined to the Narrows and Western Basin of Long Island Sound. Those areas comprise the section of the Sound west of a line from Stratford, CT to Port Jefferson, NY. The maximum extent of the hypoxic condition typically occurs in early August.

CT DEEP conducted eight cruises during the summer of 2015 between 28 May and 16 September. Over the course of the season, five (5) different stations were documented as hypoxic and of the 252 site visits completed in 2015, hypoxic conditions were found four surveys. Compared to the previous 24-year average, 2015 was below average in area and near average in duration. In fact, 2015 had the second smallest area behind 1997 (see page 9).

| Cruise | Start <br> Date | End Date | Number of <br> stations sampled | Number of <br> hypoxic stations | Hypoxic Area <br> $\left(\mathrm{mi}^{2}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| WQJUN15 | $5 / 28 / 15$ | $6 / 5 / 15$ | 17 | 0 | 0 |
| HYJUN15 | $6 / 17 / 15$ | $6 / 19 / 15$ | 28 | 0 | 0 |
| WQJUL15 | $7 / 6 / 15$ | $7 / 8 / 15$ | 40 | 0 | 0 |
| HYJUL15 | $7 / 20 / 15$ | $7 / 23 / 15$ | 39 | 3 | 29.4 |
| WQAUG15 | $8 / 3 / 15$ | $8 / 6 / 15$ | 39 | 3 | 34.8 |
| HYAUG15 | $8 / 17 / 15$ | $8 / 19 / 15$ | 36 | 3 | 38.3 |
| WQSEP15 | $8 / 31 / 15$ | $9 / 2 / 15$ | 31 | 2 | 21.7 |
| HYSEP15 | $9 / 16 / 15$ | $9 / 16 / 15$ | 22 | 0 | 0 |

The peak event occurred during the HYAUG15 cruise between 17 and 19 August. The lowest dissolved oxygen concentration ( $2.12 \mathrm{mg} / \mathrm{L}$ ) was documented during the HYJUL15 and HYAUG15 cruises at Station A4. The hypoxia area maps for 2015 appear on pages 12-21.

## Based on CT DEEP and NEIWPCC-IEC data

$$
\begin{array}{lc}
\text { Estimated Start Date } & 7 / 16 / 2015 \\
\text { Estimated End Date } & 9 / 10 / 2015 \\
\text { Duration (days) } & 57 \\
\text { Maximum Area }\left(\mathrm{mi}^{2}\right) & \mathbf{3 8 . 3}
\end{array}
$$

Start date and end date are estimated by plotting CT DEEP and NEIWPCC-IEC data from stations A4 and B3 in Excel using a line with markers chart and then interpolating when the DO concentration drops below/rises above $3.0 \mathrm{mg} / \mathrm{L}$.

## Duration Based on Buoy Data Obtained From the LISICOS Network on 28 September 2015

The figure below is from the LISICOS website and depicts the 2015 real-time bottom dissolved oxygen data (blue line); the average of the 10 year dataset (black line); and the variability observed over the historical station record (gray shading) from the Execution Rocks Buoy. The Western Sound Buoy was offline the entire summer after sustaining damage over the winter of 2014-2015.

## Based on LISICOS Buoy Data Collected Between 1 June to 28 September

| Estimated Start Date | $7 / 12 / 15$ |
| :--- | :---: |
| Estimated End Date | $9 / 21 / 15$ |
| Duration below $3.0 \mathrm{mg} / \mathrm{L}$ (cumulative days) | 50.07 |
| Duration below $2.0 \mathrm{mg} / \mathrm{L}$ (cumulative days) | 22.25 |
| Duration below $1.0 \mathrm{mg} / \mathrm{L}$ (cumulative days) | 0.00 |
| Minimum DO value ( $\mathrm{mg} / \mathrm{L}$ ) | 1.09 (21 August) |

Data obtained from the LISICOS Execution Rocks Buoy Bottom Dissolved Oxygen Prediction Tool webpage (http:///isicos.uconn.edu/do_fcst.php?site=exrx). Duration is calculated by LISICOS by summing the time (in days) of the number of samples where DO was below the specified value (T. Fake, pers comm. 18 October 2012). Data are provisional and subject to change.

## Timing and Duration of Hypoxia, 1991-2015

| Year | Estimated Start Date | Estimated End Date | Maximum Area (mi') | Duration (days) |
| :---: | :---: | :---: | :---: | :---: |
| 1991 | July 19 | Aug 28 | 122 | 41 |
| 1992 | July 7 | Aug 30 | 80 | 55 |
| 1993 | July 9 | Sept 10 | 202 | 64 |
| 1994 | July 1 | Sept 6 | 393 | 68 |
| 1995 | July 12 | Aug 15 | 305 | 35 |
| 1996 | Aug 10 | Sept 12 | 220 | 34 |
| 1997 | July 27 | Sept 12 | 30 | 48 |
| 1998 | July 5 | Sept 15 | 168 | 73 |
| 1999 | July 2 | Aug 21 | 121 | 51 |
| 2000 | July 2 | Aug 6 | 173 | 35 |
| 2001 | July 10 | Sept 14 | 133 | 66 |
| 2002 | June 25 | Aug 28 | 130 | 65 |
| 2003 | July 5 | Sept 3 | 345 | 61 |
| 2004 | July 20 | Sept 12 | 202 | 55 |
| 2005 | July 14 | Sept 20 | 177 | 69 |
| 2006 | July 6 | Aug 27 | 199 | 53 |
| 2007 | July 16 | Sept 11 | 162 | 58 |
| 2008 | July 3 | Sept 19 | 180.1 | 79 |
| 2009 | July 19 | Sept 1 | 169.1 | 45 |
| 2010 | July 5 | August 13 | 101.1 | 40 |
| 2011 | July 6 | August 28 | 130.3 | 54 |
| 2012 | July 10 | Sept 10 | 288.5 | 63 |
| 2013 | July 8 | Sept 7 | 80.7 | 62 |
| 2014 | July 24 | Sept 9* | 87.1 | 35 |
| 2015 | July 16 | Sept 10 | 38.3 | 57 |
| Average | July 12 | Sept 4 | 169 | 55 |
| Deviation | $\pm 10$ days | $\pm 12$ days | $\pm 87 \mathrm{mi}^{2}$ | $\pm 13$ days |

The figure and table below display the onset, duration, and end of the hypoxia events from 1991 through 2015 based on the $3.0 \mathrm{mg} / \mathrm{L}$ standard.

Based on the LISS standard of 3.0 $\mathrm{mg} / \mathrm{L}$, the average date of onset was July 12 ( $\pm 10$ days), the average end date was September 4 ( $\pm 12$ days), and the average duration was 55 days $( \pm 13$ days). The earliest onset of hypoxia (red text) occurred on 25 June 2002 and the latest end date (green text) occurred on 20 September 2005. The maximum area of hypoxia was 393 square miles (blue text) and occurred in 1994. The longest hypoxic event occurred in 2008 (magenta text) and lasted 79 days.

* In 2014 there was a clear period of 14 days where the DO concentration rose above the $3.0 \mathrm{mg} / \mathrm{L}$ threshold in the middle of August before dipping again during late August and early September.

Timing and Duration of Hypoxia based on $3.0 \mathrm{mg} / \mathrm{L}$

## Yearly Comparison of Maximum Areal Extent and Duration of Hypoxia

This graph utilizes the data presented on the previous page to illustrate the year-to-year differences in the maximum areal extent of hypoxic conditions. Based on the $3.0 \mathrm{mg} / \mathrm{L}$ DO standard the average areal extent was $169.5 \mathrm{mi}^{2}$ and the average duration was 55 days.

Area and Duration of Hypoxia ( $\mathrm{DO}<3.0 \mathrm{mg} / \mathrm{L}$ )

Departure from Normal Temperature ( ${ }^{\circ} \mathrm{F}$ ) June 1-August 31, 2015

Percent of Normal Precipitation (\%) June 1- Aug 31, 2015

## 2015 Summer Weather Conditions

The Northeast Regional Climate Center at Cornell is tasked with disseminating climate data and information for 12 states. The NRRC included the following graphics in their Eastern Region Quarterly Climate Impacts and Outlook Summary September 2015.
http://www.nrcc.cornell.edu/services/reports/reports/2 015-09.pdf

Average spring air temperatures were below normal for the area through March but warmer to above normal in May. June saw average temperatures across the region. July and August average temperatures across the region were above normal by 2-3 degrees. Record warmth was seen at Kennedy Airport during August. September temperatures continued above normal with Islip, NY marking the first part of the month as its warmest on record, 5 degrees above normal. Bridgeport, CT reported its second warmest September on record.

Spring precipitation was below normal for CT and Long Island, resulting in moderate drought conditions across the region. June was wetter than May, but abnormally dry conditions persisted into July and August On the last day of September, a slow moving cold front combined with remnants of a tropical system to bring 1-2 inches of rain to the region. Precipitation continued to be scarce through October and into November with the region classified as being abnormally dry or in a moderate drought by the US Drought Monitor http://www.nrcc.cornell.edu/page_drought.html.

This information is useful as physical processes influence the timing and duration of hypoxia.

## Hypoxia Maps

The following maps depict the development of hypoxia based on CT DEEP cruise data through the 2015 season. Data for all surveys are available upon request. NEIWPCC-IEC data were also mapped to provide additional details on hypoxic conditions in the far western Sound. IEC data are considered provisional. IEC data are not utilized to estimate the areal extent of hypoxia.

During the WQJUN15 and HYJUN15 survey all stations (CT DEEP and IEC) had DO concentrations above $4.8 \mathrm{mg} / \mathrm{L}$; therefore, no maps were produced.

## HYJUL15

During IEC Run \#3, 11 out of 21 stations exhibited DO concentrations below 4.8 $\mathrm{mg} / \mathrm{L}$. Of those, Station B2 was at $3.0 \mathrm{mg} / \mathrm{L}$ and three stations were below $3.0 \mathrm{mg} / \mathrm{L}$.

During the HYJUL15 survey, DO concentrations dropped below $4.8 \mathrm{mg} / \mathrm{L}$ at 12 stations with three stations below $3.0 \mathrm{mg} / \mathrm{L}$.

IEC Run \#4 occurred two weeks prior to the CTDEEP WQAUG15 survey. At Station A4 the DO was $3.5 \mathrm{mg} / \mathrm{L}$.
Station B3 was at 3.3 $\mathrm{mg} / \mathrm{L}$. Stations A3, HA-3, and H-C1 dropped below 3.0 $\mathrm{mg} / \mathrm{L}(2.5,2.7$, and $2.1 \mathrm{mg} / \mathrm{L}$, respectively).

IEC Run \#5 occurred on $7 / 28 / 15$, a week prior to the CTDEEP WQAUG15 survey. Sixteen (16) stations were less than 4.8 $\mathrm{mg} / \mathrm{L}$. Of those, four were less than 3.5 $\mathrm{mg} / \mathrm{L}$ and one station, 9-413, was less than $2.0 \mathrm{mg} / \mathrm{L}$. At Station A4 the DO was 2.6 $\mathrm{mg} / \mathrm{L}$. Station B3 was at $3.5 \mathrm{mg} / \mathrm{L}$.

## WQAUG15

During the WQAUG15 survey, DO concentrations were below $3.0 \mathrm{mg} / \mathrm{L}$ at three stations. At Station B3 and A4, concentrations continued to be between 2.0 and $3.0 \mathrm{mg} / \mathrm{L}$. DO concentrations at Station 02 were less than $3.5 \mathrm{mg} / \mathrm{L}$

During IEC Run \#6 only one station was above $4.8 \mathrm{mg} / \mathrm{L}$.
Eleven stations were less than $3.5 \mathrm{mg} / \mathrm{L}$ and three stations were less than $3.0 \mathrm{mg} / \mathrm{L}$.

During IEC Run \#7 conditions improved slightly with 11 stations exhibiting DO concentrations above $4.8 \mathrm{mg} / \mathrm{L}$. Six stations were less than $4.8 \mathrm{mg} / \mathrm{L}, 4$ stations were less than $3.5 \mathrm{mg} / \mathrm{L}$ and five stations were less than $3.0 \mathrm{mg} / \mathrm{L}$.

## HYAUG15

Concentrations degraded for IEC Run \#8 with DO at 7 stations measuring less than $3.0 \mathrm{mg} / \mathrm{L}$.

During the HYAUG15 survey DO concentrations across the Sound were less than $3.0 \mathrm{mg} / \mathrm{L}$ at 3 stations. Two stations had concentrations between 3.0 and $3.5 \mathrm{mg} / \mathrm{L}$. 28 stations had concentrations between $3.5 \mathrm{mg} / \mathrm{L}$ and $4.8 \mathrm{mg} / \mathrm{L}$. This would be the height of the hypoxic event. 2015 had the second lowest areal extent over the course of the 25 -year sampling program, with only 1997 having a lower areal extent.

During IEC Run \#9 conditions degraded with 2 stations exhibiting DO concentrations below $2.0 \mathrm{mg} / \mathrm{L}$. Five stations were less than $3.0 \mathrm{mg} / \mathrm{L}$, two stations were less than 3.5 $\mathrm{mg} / \mathrm{L}$, and eight stations were less than $4.8 \mathrm{mg} / \mathrm{L}$.

## WQSEP15

The WQSEP15 survey and IEC Run \#10 found conditions had improved slightly. Concentrations at A4 and B3 were 2.52 and $2.99 \mathrm{mg} / \mathrm{L}$, respectively. Stations C1 and 01were below $3.5 \mathrm{mg} / \mathrm{L}$ and 18 stations were below $4.8 \mathrm{mg} / \mathrm{L}$. IEC found similar conditions, with three stations exhibiting concentrations below $3.0 \mathrm{mg} / \mathrm{L}$ and nine stations below $3.5 \mathrm{mg} / \mathrm{L}$.

During IEC Run \#11 conditions improved slightly. Four stations had DO concentrations less than $3.0 \mathrm{mg} / \mathrm{L}$, six stations were less than $3.5 \mathrm{mg} / \mathrm{L}$, and eight stations were less than $4.8 \mathrm{mg} / \mathrm{L}$.

## HYSEP15

Conditions rebounded for the HYSEP15 survey with only one CT DEEP station exhibiting DO concentrations below $4.8 \mathrm{mg} / \mathrm{L}$ (A4). IEC sampled two days prior to CT DEEP and found 11 stations with DO less than $4.8 \mathrm{mg} / \mathrm{L}$. The LISICOS buoy data showed concentrations climbing above $3.0 \mathrm{mg} / \mathrm{L}$ and staying above 3 beginning on or about 14 September.
Dissolved Oxygen in Long Island Sound Bottom Waters

## Area of Dissolved Oxygen Below the Chronic Criterion for Growth and Protection of Aquatic Life for LIS

Aquatic organisms are harmed based on a combination of minimum oxygen concentration and duration of the low DO excursion. CT DEEP established Dissolved Oxygen Chronic Exposure Criteria based on research and data collected by the EPA. A DO concentration of $4.8 \mathrm{mg} / \mathrm{L}$ meets the chronic criterion for growth and protection of aquatic life regardless of the duration.

This chart illustrates the maximum area of bottom waters within Long Island Sound with DO concentrations less than $4.8 \mathrm{mg} / \mathrm{L}$. In 2015, the maximum area below $4.8 \mathrm{mg} / \mathrm{L}$ occurred during the HYAUG15 survey and was estimated at 559 square miles. From 1991-2015, the area affected by concentrations less than $4.8 \mathrm{mg} / \mathrm{L}$ averages 593.9 square miles and varies slightly from 414 to 730 square miles.

## Severe Hypoxia

The Long Island Sound Study provides information on LIS Hypoxia for inclusion in EPA's Report on the Environment (http://www.epa.gov/ncea/roe) which reports on "the best available indicators of information on national conditions and trends in air, water, land, human health, and ecological systems...". The ROE Report uses $2.0 \mathrm{mg} / \mathrm{L}$ as a benchmark to liken conditions in the Gulf of Mexico to LIS. In this report, the term severe hypoxia is used to describe $\mathrm{DO}<2.0 \mathrm{mg} / \mathrm{L}$ and is discussed below.

This chart illustrates the maximum area of bottom waters of Long Island Sound with concentrations less than 2 $\mathrm{mg} / \mathrm{L}$. Based on CT DEEP data, in 2015, bottom water dissolved oxygen concentrations were all greater than $2.0 \mathrm{mg} / \mathrm{L}$ (i.e., area $<2.0 \mathrm{mg} / \mathrm{L}=0 \mathrm{mi}^{2}$ ). The average area with concentrations less than $2.0 \mathrm{mg} / \mathrm{L}$, calculated from 1991-2015, is $53.2 \mathrm{mi}^{2}$. Based on the LISICOS Execution Rocks data there were 22.25 cumulative days below $2.0 \mathrm{mg} / \mathrm{L}$.

For comparisons, the 30-year average size of the hypoxic zone in the northern Gulf of Mexico is roughly 5312 $\mathrm{mi}^{2}$ (larger than the State of CT). The maximum area of the Gulf of Mexico hypoxic zone occurred in 2002 and was estimated at $8,841 \mathrm{mi}^{2}\left(22,898 \mathrm{~km}^{2}\right)$. The 2015 hypoxic zone covered $6474 \mathrm{mi}^{2}\left(16760 \mathrm{~km}^{2}\right)$ and was larger than 2014 (http://www.gulfhypoxia.net/Research/Shelfwide\ Cruises/2015/PressRelease2015.pdf).

In LIS, 1994 and 2003 appear to be especially bad years for concentrations less than $2 \mathrm{mg} / \mathrm{L} .1994$ had cold winter bottom water temperatures and an unually warm June which led to the establishment of strong stratification. The highest average Delta T in July 1994 was $8.54^{\circ} \mathrm{C} .2003$ was the second hottest summer since 1895 and the 28th wettest which also led to the Sound being very strongly stratified. Strong stratification (Delta T greater than 4) lasted for four months in 1994 (May-August) and only one month (July) in 2003.

## Anoxia D.O. $<1 \mathrm{mg} / \mathrm{L}$

For management purposes the Long Island Sound Study defines anoxia as DO concentrations less than $1 \mathrm{mg} / \mathrm{L}$. In 12 of the twenty-five years there was no anoxia reported by CT DEEP. The greatest area with DO below $1 \mathrm{mg} /$ L observed in LIS, based on ~biweekly sampling by CT DEEP, was during the summer of 2003. Prior to 2002, the average area of bottom waters affected by anoxia was $5.92 \mathrm{mi}^{2}$. From 2002-2012 the average area affected was $22.24 \mathrm{mi}^{2}$. The overall average area affected from 1991-2015 is $12.4 \mathrm{mi}^{2}$. A consistent decline was observed from 2003-2007. During the summer of 2008 three stations (A4, B3, and 02) were observed to have gone anoxic. In 2009, 2010, and 2011 CT DEEP did not document any stations with DO $<1 \mathrm{mg} / \mathrm{L}$. However, in 2009 and 2010 the Interstate Environmental Commission documented two stations that were anoxic. In 2011, no stations were documented to have gone anoxic by either the IEC or CT DEEP. However, the lowest concentration reported at the LISICOS Execution Rocks buoy (Station A4) for 2011 was $0.61 \mathrm{mg} / \mathrm{L}$. In 2012, CT DEEP documented two stations that were anoxic (A4 and B3). IEC documented two anoxic stations (A3 (further west than A4, Hewlett Point and H-C in Hempstead Harbor). LISICOS also documented anoxic conditions ( 4.04 days and minimum DO of $0.52 \mathrm{mg} / \mathrm{L}$ ). In 2013, 2014, and 2015 anoxic conditions were not documented by CT DEEP, IEC or LISICOS.

## HABITAT IMPAIRMENT ASSOCIATED WITH HYPOXIA

For Long Island Sound, DO levels below $3 \mathrm{mg} / \mathrm{L}$ are considered hypoxic, causing mobile animals to leave and sessile animals to die or be physically or behaviorally impaired. However, DO can become limiting below $4.8 \mathrm{mg} / \mathrm{L}$ for sensitive fish species, such as whiting and scup, while more tolerant species, such as butterfish, bluefish, lobster and Atlantic herring, are not affected until DO falls below $2 \mathrm{mg} / \mathrm{L}$.

An index of habitat impairment, "Biomass Area-Day Depletion" (BADD) was developed by CT DEEP Marine Fisheries Division based on extensive sampling in the Sound from 1986-1993. Instead of individual species' responses to low oxygen, an aggregate response of 18 demersal (bottom-dwelling) finfish species was calculated as a general index of the impact on living resources to low oxygen conditions at or near the bottom of the Sound. The total weight, or biomass, of these demersal finfish species captured in samples taken at various levels of low DO was quantified and the percent reduction in biomass from that captured in fully oxygenated water was computed. These studies showed that the finfish biomass is reduced by $100 \%$ (total avoidance) in waters with DO less than $1.0 \mathrm{mg} / \mathrm{L}$. In waters with $1.0-$ $1.9 \mathrm{mg} / \mathrm{L}$ DO, biomass is reduced by $82 \%$, while a $41 \%$ reduction occurs at $2.0-2.9 \mathrm{mg} / \mathrm{L} D O$, and a $4 \%$ reduction occurs at 3.0-3.9 $\mathrm{mg} / \mathrm{L} D O$.

For each survey the total area of the Sound encompassing each 1-mg interval of DO is calculated and the depletion percentage applied. These area depletions are summed over the number of days they persist during the designated hypoxia season. The summed area-day depletion is then expressed as a percentage of the total available area (total sample area of $2,723 \mathrm{~km}^{2}$ ) multiplied times the total season (94 days). A maximum BADD index of $100 \%$ would result from severe hypoxia occurring over the entire study area for the entire hypoxia season.

In an average year, hypoxic waters cover $\sim 440 \mathrm{~km}^{2}$ (169 miles2) for 55 days and result in a BADD impairment index of $2.5 \%$. In the worst year, hypoxia spread over $1,000 \mathrm{~km}^{2}\left(395\right.$ miles $\left.^{2}\right)$ for the entire season, resulting in a BADD index of almost $6 \%$. In 2015, the BADD index was $0.77 \%$.
-Penny Howell, Fisheries Biologist, CT DEEP Marine Fisheries Division, CT Wildlife Article, July/August 2014

BADD index

Simpson, David G., Kurt Gottschall, and Mark Johnson. 1995. Cooperative interagency resource assessment (Job 5). In : A study of marine recreational fisheries in Connecticut, CT DEP Marine Fisheries Office, PO Box 719, Old Lyme, CT 06371, p 87-135.

## WATER TEMPERATURE AND HYPOXIA

In LIS, water temperature plays a major role in the ecology of the Sound especially in the timing and severity of the summer hypoxia event. CT DEEP's monitoring program records water temperatures and salinity year round, but data collected during the hypoxia monitoring cruises are used to help estimate the extent of favorable conditions for the onset, extent, and end of the hypoxic event. The conceptual diagram below, while developed for Chesapeake Bay, applies to Long Island Sound. In LIS, there are two key contributors to hypoxia: nutrient enrichment and stratification. (Stratification is discussed more on page 24.) Nutrients, especially nitrogen, flow into the Sound from numerous sources including point sources like wastewater treatment plants and nonpoint sources such as stormwater runoff. This enrichment leads to excessive growth of phytoplankton, particularly in the spring. Temperature can stimulate or impede phytoplankton growth. As the plankton die, they begin to decay and settle to the bottom. Bacterial decomposition breaks down the organic material from the algae, using up oxygen in the process.

## 2015 Water Temperature Data

2015 maximum, minimum, and average water temperature $\left({ }^{\circ} \mathrm{C}\right)$ data are summarized below. Data are integrated across Long Island Sound (i.e., all stations and all depths) and are displayed by cruise. Data were obtained using the CT DEEP Sea Bird Sea Cat Conductivity, Temperature, Depth (CTD) profiler.

| Cruise | 2015 <br> Max | $1991-2015$ <br> Max | 2015 <br> Min | $1991-2015$ <br> Min | 2015 <br> Average | $1991-2015$ <br> Average |

The Sound is coldest during February and March and warmest during August and September. The yearly average surface and bottom temperature of the Sound show slight increases over the period 1991-2015.

Long Island Sound Average Summer Bottom Water Temperatures 2008-2015

Water temperatures in 2015 mimicked air temperatures with May and June averages below the 20082015 mean and August and September being above.

While box plots were not prepared using winter water temperature data, February, March and April were certainly cold; 2015 was the first time in at least nine years that the $\mathrm{R} / \mathrm{V}$ John Dempsey was iced in at Milford Harbor.

## Delta T and Stratification

The temperature difference between the bottom waters and the surface waters is known as "Delta T". This Delta T, along with salinity differences, creates a density difference, or "density gradient" resulting in a separation or "stratification" of water layers that hinders the oxygenated surface waters from circulating downward and mixing with the oxygen starved bottom waters. The pycnocline, or zone where water density increases rapidly with depth due to the changes in temperatures and salinity, inhibits oxygenated surface waters from mixing with oxygen deplete bottom waters exacerbating the hypoxia. The pycnocline typically develops in LIS in late spring/early summer when rapid surface water warming exceeds the rate of warming in the bottom waters and persists into early fall when it is disrupted by strong winds associated with storms which lead to mixing or cooling air temperatures. With the dissolution of the pycnocline, hypoxic conditions are alleviated/eliminated. The smallest Delta Ts occur during the winter when the water column is well mixed. The largest Delta T's occur during the early summer. The greater the delta T the greater is the potential for hypoxia to be
 more severe
The temperature graphs on page 30 show computer interpolations along the west-east axis of LIS generated from profile data collected during two CT DEEP surveys. During the HYJUL15 survey, surface water temperatures had warmed to an average of $22.72^{\circ} \mathrm{C}$ while the bottom water remained cooler around an average of $18.57^{\circ} \mathrm{C}$. This set up the largest differences in temperatures between the surface and bottom waters with Delta-T's between 0.97 and $9.42^{\circ} \mathrm{C}$. The second graph shows how the water column was thermally stratified during the HYAUG15 survey when hypoxic conditions were at their worst. The temperature area maps on page 31 show how the Delta T's varied over the course of the summer sampling season. Delta T's increased from the WQAPR15 survey through the HYJUL15 survey, setting up the stratification and leading to the maximum extent of hypoxia in late August. By the September survey Delta T's decreased to around $1.5^{\circ} \mathrm{C}$ over much of the Sound. Delta T's continued to decrease during the HYSEP14 survey to around $0.1^{\circ} \mathrm{C}$, allowing the oxygenated surface waters to mix through to the bottom, leading to the end of the hypoxic event. The maps also show how the Delta T varies spatially. The western Sound typically has higher Delta T's due to the limited flushing capacity, topology, and geology. In the east where cooler, oxygen rich, off- shore ocean water mixes with the Sound water, Delta T's are much lower and hypoxia rarely occurs. This year the Central Sound had the highest Delta T's.

In Situ Temperature Profiles Obtained During the HYJUL15 Long Island Sound Hypoxia Survey

## 2015 Delta-T Maps

| $\square 0-0.5$ | $\square$ | $>2.5-3$ | $\square$ | $>5-5.5$ |  | $>7.5-8$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\square$ | $>0.5-1$ | $\square$ | $>3-3.5$ | $\square$ | $>5.5-6$ | $\square$ |

Delta-T ${ }^{\circ} \mathrm{C}$

This table summarizes the minimum winter temperatures (January, February, and March), the maximum summer temperatures (June, July, August, and September), the maximum Delta T, and maximum hypoxic area at Station D3. Station D3 is located in the eastern-most and deepest portion of the Narrows (see map on page 1). The CT DEP 1991-1998 Data Review report (Kaputa and Olsen, 2000) found a positive correlation between the maximum Delta T observed at D3 and the maximum area of hypoxia in the same year. Delta T was not correlated to the duration of hypoxia. 2012 had the warmest minimum winter temperature, 2015 had the lowest winter temperature recorded, 2014 had the highest summer temperature, 2011 had the highest $\Delta \mathrm{Tmax}$, and 1994 had the largest area of hypoxia.

| Year | Minimum Winter Temp $\left({ }^{\circ} \mathrm{C}\right)$ | Maximum Summer Temp $\left({ }^{\circ} \mathrm{C}\right)$ | Maximum $\Delta \mathrm{T}\left({ }^{\circ} \mathrm{C}\right)$ | $\begin{gathered} \text { Maximum Area of Hypoxia } \\ \left(\mathrm{mi}^{2}\right) \\ \mathrm{DO}<3.0 \mathrm{mg} / \mathrm{L} \\ \hline \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: |
| 1991 | 2.69 | 22.23 | 4.75 | 122 |
| 1992 | 1.86 | 20.89 | 4.83 | 80 |

| 2015 | -1.1 | 24.23 | 6.71 | 38.3 |

[^2]

Time series of $\Delta \mathrm{T}$ (surface water temperature - bottom water temperature) at station D3, 1991 through 2015.

Prior to 2004, when Station D3 became hypoxic the observed maximum delta-T was greater than $5^{\circ} \mathrm{C}$. Since 2004, this trend/pattern does not seem to hold. Over the period of record, 2011 had the highest observed Delta T at Station D3 $\left(>8^{\circ} \mathrm{C}\right)$ but the lowest dissolved oxygen concentration recorded in 2011 at D3 was $3.22 \mathrm{mg} / \mathrm{L}$. In 2012, the Delta T was again over $5^{\circ} \mathrm{C}$ and D 3 was in fact hypoxic (lowest dissolved oxygen was 2.84 $\mathrm{mg} / \mathrm{L}$ ). In 2013, D3 was not hypoxic despite the Delta T again being over $5^{\circ} \mathrm{C}$ (lowest concentration was $3.13 \mathrm{mg} / \mathrm{L}$ ). In 2014, the maximum Delta T at D 3 was $6.90^{\circ} \mathrm{C}$ but D3 was not hypoxic (lowest DO $3.33 \mathrm{mg} / \mathrm{L}$ ). In 2015 , the maximum Delta T at D 3 was $6.71^{\circ} \mathrm{C}$ and the station was not hypoxic (lowest DO $3.5 \mathrm{mg} / \mathrm{L}$ ).

## Salinity

Salinity is a measure of the dissolved salts content of seawater. It is usually expressed in practical salinity units (PSU). Salinity levels across Long Island Sound vary from 23 PSU in the Western Sound at Station A4 to 33 PSU in the eastern Sound at Station M3. The Thames, Connecticut, and Housatonic rivers are the major sources of freshwater entering the Sound. Summary statistics for salinity data collected from seven stations across the Sound from 19912015 are presented in the tables below. Data collected this year are also presented separately.

Boxplot of Surface Salinity Data from LIS
January 1991- September 2015

This box plot, based upon data collected during CT DEEP surveys from January 1991 September 2015, shows the median surface salinity, range, interquartile range, and outliers by station. Surface in this case refers to data collected two (2) meters below the air/water interface. Salinity increases from west to east across the Sound.

This box plot, based upon data collected during CT DEEP surveys from January 1991September 2015 shows the median bottom salinity, range, interquartile range, and outliers by station. Bottom in this case refers to data collected five (5) meters above the sediment/water interface. The bottom waters are generally saltier than the surface waters.

Boxplot of Bottom Salinity Data from LIS
January 1991-September 2015

## Average Salnity Data from LIS

January through September 2015

This plot illustrates the temporal variability of the mean salinity values by station from January-
September 2015.

## Water Clarity

Water clarity is measured by lowering a Secchi disk into LIS by a measured line until it disappears. It is then raised until it reappears. The depth where the disk vanishes and reappears is the Secchi disk depth. The depth to disappearance is related to the transparency of the water. Transparency may be reduced by both absorption and scattering of light. Water absorbs light, but absorption is greatly increased by the presence of organic acids that stain the water a brown "tea" color and by particles. Scattering is largely due to turbidity, which can be attributable to both inorganic silt or clay particles, or due to organic particles such as detritus or planktonic algae suspended in the water. CT DEEP began taking Secchi Disk measurements in June 2000. Since then, 3368 measurements have been entered into our database; of those 2,035 are from the 17 stations sampled annually. The 2000-2015 average Secchi depth is 2.4 m with a minimum depth of 0.4 m (WQSEP05, station A4) and a maximum depth of 6.2 m (WQNOV00 Station K2). Below is a graph depicting Secchi disk depths from six of the axial stations sampled by CT DEEP LISS Water Quality Monitoring Program between May and September 2015.

2014 data

- Average Secchi Disk Depth: 2.83 m ( $\mathrm{n}=294$ )
- Minimum Secchi Disk Depth: $\mathbf{1 . 0} \mathbf{m}$ on multiple dates/stations
- Maximum Secchi Disk Depth: 5.1 m at Station 09 during the WQAPR14 cruise

2015 data

- Average Secchi Disk Depth: 2.71 m ( $\mathrm{n}=269$ )
- Minimum Secchi Disk Depth: 1.0 m at Station K2 during the WQJAN15 cruise
- Maximum Secchi Disk Depth: 5.0 m at Stations H4 during the WQSEP15 cruise 36

The Integration and Application Network at the University of Maryland Center for Environmental Science prepared a Report Card for Long Island Sound (based on 2013 data) that was released to the public in 2015 (http://ecoreportcard.org/report-cards/long-island-sound/). One of the indicators included in the Report Card is water clarity (Secchi disk depth).

The newly released Long Island Sound Comprehensive Conservation and Management Plan has identified improving water clarity as a goal to support healthy eelgrass communities. Water clarity is one of the major factors affecting eelgrass health and therefore extent. The CCMP states "For the purposes of this goal, "improved" is defined as an increase in the overall numeric criterion for water clarity in the Long Island Sound water quality report card by at least half letter grade (e.g., B to $\mathrm{B}+$ ) between the initial 2015 report card evaluation and the evaluation conducted in 2035.

CT DEEP created maps similar to that found in the Report Card using the 2015 average Secchi depth data (JanuaryOctober) from our 17 monthly water quality monitoring stations. Average Secchi depths across the Sound ranged from 1.95 m at Station A4 to 3.93 m at Station M3. Water clarity seems to have improved slightly from 2013 when the average Secchi depth at A4 was 1.71 m and at M3 was 3.24 m . However, recall that 2015 was abnormally dry. Therefore, the improved water clarity may simply be the result of decreased precipitation and fewer suspended solids entering the water column.

| Criteria <br> Threshold <br> $(\mathbf{m})$ | Overall Score <br> Calculation |
| :---: | :---: |
| $<0.7$ | Fail (0\%) |
| $0.7-1.1$ | Marginal $(33.3 \%)$ |
| $1.1-2.4$ | Fair $(66.7 \%)$ |
| $>2.4$ | Pass $(100 \%)$ |

## pH and Ocean Acidification

Human activities have resulted in increases in atmospheric carbon dioxide $\left(\mathrm{CO}_{2}\right)$. The ocean absorbs $\mathrm{CO}_{2}$, greatly reducing greenhouse gas levels in the atmosphere and minimizing the impact on climate. When $\mathrm{CO}_{2}$ dissolves in seawater carbonic acid is formed. This acid formation reduces the pH of seawater and reduces the availability of carbonate ions. Carbonate ions are utilized by marine organisms in shell and skeletal formation. According to the NOAA Pacific Marine Environmental Laboratory Ocean Acidification Home Page, the pH of the ocean surface waters has already decreased from an average of 8.21 SU to 8.10 SU since the beginning of the industrial revolution and the Intergovernmental Panel on Climate Change predicts a decrease of an additional 0.3 SU by 2100. (See
http://www.pmel.noaa.gov/co2/OA/background.html.)
With this issue in mind, CT DEEP upgraded its SeaCat Profilers and began collecting and reporting pH data in August 2010. Data collected through the HYSEP15 survey are summarized below.

|  | n | Maximum Minimum | Mean | Median | SE Mean | StDev | Variance | Q1 | Q3 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Near Btm | 1188 | 8.415 | 7.003 | 7.6754 | 7.6585 | 0.00792 | 0.2729 | 0.0745 | 7.461 | 7.885 |
| Bottom | 1242 | 8.762 | 6.061 | 7.8202 | 7.7985 | 0.00885 | 0.312 | 0.0974 | 7.593 | 8.0563 |
|  | 1896 | 8.806 | 6.066 | 7.896 | 7.877 | 0.00659 | 0.287 | 0.0824 | 7.68 | 8.12 |

## Boxplot of LIS pH

August 2010- September 2015

## Chlorophyll a

Chlorophyll is a pigment found in plants that gives them their green color. It allows plants to absorb light from the sun and convert it to chemical energy during photosynthesis. In photosynthesis carbon dioxide and water are combined to produce sugar giving off oxygen as a byproduct. Microscopic plants, called phytoplankton, form the basis of the food web in Long Island Sound. However, as in most cases in nature, too much phytoplankton may not be a good thing.
 Water temperature, nutrient concentrations, and light availability all factor into the amount of phytoplankton biomass found in the Sound.

The concentration of chlorophyll $a$ is used as a measure to estimate the quantity of phytoplankton biomass suspended in the surface waters. It is most commonly used because it is easy to measure and because photosynthetic production is directly proportional to the amount of chlorophyll present.

Chlorophyll a concentrations are measured in situ using the CTD fluorometer as well as through the collection of grab samples using Niskin bottles. The grab samples are brought back into the onboard lab, filtered, and then sent to UConn for analysis.

The spring phytoplankton bloom occurs in Long Island Sound between February and April. Historically high levels of chlorophyll a in the western Sound during this time have been linked to summertime hypoxia conditions.

Unfortunately, April-October chlorophyll a data are not yet available from UConn. As a result, we are unable to evaluate the timing of the spring bloom or compare the chlorophyll concentrations to the thresholds put forth in the Long Island Sound Report Card.

## National Coastal Condition Assessment Sampling 2015

In 2015, CTDEEP participated in the NCCA, which is an EPA statistical survey on the condition of our Nation's marine water.

The survey aims to address two key questions:

- What percent of the Nation's coastal waters are in good, fair, and poor condition for key indicators of water quality, ecological health, and recreation?
- What is the relative importance of key stressors such as nutrients and contaminated sediments?

CTDEEP sampled 22 sites for water quality, sediment quality, benthic community condition, and fish tissue contaminants.

Additional information on the surveys can be found on EPA's website:
http://www2.epa.gov/national-aquatic-resource-surveys/national-coastal-condition-assessment.

## JOB 11 PUBLIC OUTREACH

## GOAL

To increase awareness among anglers and the general public of the information products provided by this project and how this information contributes to state and federal efforts to enhance, restore and protect marine habitat and recreational fish populations.

## OBJECTIVES

1) Increase public awareness that research \& monitoring are essential to good fisheries management and the majority of marine fisheries research \& monitoring activities in Connecticut are funded through excise tax on fishing tackle and motorboat fuels

## SUMMARY

1. A total of 17,296 outdoor and environmental writers, marine anglers and boaters, marina operators, fishing tackle retailers, Fisheries Advisory Council (FAC) members, students, and members of the general public attended outreach events. The importance of research and monitoring to good fisheries management was incorporated into the programs (Table 11.2).
2. These same audiences also learned that good water quality and proper pollution prevention (nonfishing impacts) are essential to good fisheries habitat management.
3. Total attendance at five engagements with sportsmen clubs and other recreational environmental clubs was 233 (Table 11.2). The audience was encouraged to become actively involved in the fishery management process by attending public hearings and FAC meetings. Notices of public hearings were sent to hundreds of tackle shops and various media outlets including the DEEP website (www.ct.gov/deep/fishing).
4. Total attendance at one career day event with a Connecticut college was 52 (Table 11.2). The students were encouraged to become actively involved in fisheries biology and management.
5. The message that the majority of marine finfish research and monitoring are funded through Federal excise taxes on fishing and motorboat fuels was emphasized at major department outreach events (Table 11.2).

## INTRODUCTION

Public outreach was formally incorporated into this project in 1997 (segment 17). An outreach plan was developed by project staff working closely with US Fish and Wildlife Service personnel. Six target audiences were identified in priority order (Table 11.1) in the outreach plan. This report summarizes F54R outreach activities conducted from March 2015 to February 2016 (segment 34).

## RESULTS AND DISCUSSION

## Outdoor and Environmental Writers

DEEP press releases, project summaries, FAC quarterly reports and full annual reports were mailed and e-mailed out to several outdoor writers, members of the CT Outdoor Recreation Coalition (CORC) and Fisheries Advisory Council (FAC). Project staff were also interviewed concerning F54R activities in person, at public and regulatory hearings, and over the telephone by writers and reporters for the news media.

## Marine Anglers and Marine Boaters

Project personnel organized and assisted in DEEP, Marine and Inland Fisheries Division displays at two statewide fishing/hunting and boating shows. The shows were sponsored by CMTA, Channel 3, Channel 30 and Connecticut Outdoor Recreation Coalition and were held in January and February of 2016 at the Connecticut Convention Center. These shows attracted 15,792 anglers, non-anglers, boaters, tackle retailers, legislators and general outdoor recreation enthusiasts. The theme for these show were "Enhanced Fishing Opportunities", Trophy Fish Close to Home" and "Marine Fisheries Division Angler Surveys". F54R activities were highlighted at these shows in displays entitled "Trophy Fish Award Program" and "Marine Angler Surveys, (a marine fisheries cooperative management program)". Audiences learned the importance of research and monitoring which are funded through excise taxes on fishing tackle and motorboat fuels. Colorful posters and pictures, brief project specific text and taxidermy reproductions helped draw attention to marine species monitored under F54R programs and solicit questions and discussion of those programs.

Several outreach displays were developed by project staff and mounted in the lobby and hallways at the Marine Fisheries Headquarters in Ferry Point State Park. These displays highlighted unique characteristics of Long Island Sound, public access, species identification, the trophy fish award program, marine angler surveys and gave a brief description of current F54R programs designed to protect the Sound's resources. These fisheries displays can easily be viewed by anglers, boaters and their families at this popular fishing and picnic area.

The Connecticut Department of Environmental Protection (DEEP) hosted the 'Eighth Annual Trophy Fish Award Ceremony' at the Northeast Fishing and Hunting Expo in the Connecticut Convention Center in Hartford on Saturday February 14, 2016. Nearly eighty (37 marine anglers)
were recognized for their fishing achievements during 2015. Six new state record holders, including one new species (Dolphinfish), were honored. The Connecticut Department of Energy \& Environmental Protection (DEEP) hosted the ceremony. Seventy-nine anglers were presented framed certificates and trophy fish award hats recognizing their achievement of having caught or landed the largest fish in one of several species categories during 2015. Another three marine anglers were recognized as angler of the year. For a summary please see: 2015 Marine Fisheries Trophy Fish Award Program Summary

## Fishing Tackle Retailers

Fishing tackle retailers provide an important avenue for communication between the department and anglers. A complete list of fishing tackle retailers is maintained and updated yearly on the CTDEEP website. Timely DEEP press releases, species fact sheets, Connecticut angler guides and Marine Fisheries Brochure are mailed to tackle retailers to keep them informed. Correspondence between the marine fisheries office staff and retailers are ongoing.

## Fisheries Advisory Council

The Fisheries Advisory Council, which represents a cross section of Connecticut residents with interests in fisheries issues, met quarterly to discuss statewide fisheries issues. For each quarterly meeting staff produce a report of recent project activities which is distributed to FAC members and posted on our web site. Marine FAC Quarterly Report. After each meeting most Council members report Council discussions back to the fishing and environmental groups they represent. Council members also discussed monitoring and funding issues at meetings with state legislators. Many Council members visited Marine Fisheries displays at the Northeast Fishing and Hunting Expo, CMTA Boating Show, Trophy Fish Award Program and other activities the Fisheries Division held during 2015-16. 'A Study of Marine Recreational Fisheries in Connecticut' was emailed to Fishery Advisory Council members to keep them informed.

## General Public

Marine Headquarters is open daily Mon-Fri. attracting thousands to the public outreach displays at the office. Display topics included all F54R projects. Activities funded under other Federal Aid in Sport Fish Restoration projects were also highlighted; including Connecticut Pumpout Stations and Waste Reception Facilities (V-4), Motorboat Access Renovation and Development (F60D), Motorboat Access Area Operation and Maintenance (F70D), and Habitat Conservation and Enhancement (F61T).

Six articles describing Sport Fish Restoration projects were published in the Department's Wildlife Magazine. The first summarized mapping wildlife action plans in marine waters. A second highlighted Atlantic sturgeon in the CT River. Other articles described what is behind minimum size regulations, CT reef fish (tautog) gets special attention, CT DEEP survey captures migrating sea turtles and lastly, mapping changes in coastal fisheries abundance. These last two articles were based on data gathered in Job 2.

Sport Fish Restoration projects were also highlighted at public schools and universities throughout the year. Presentations titled "Marine Fisheries Management / Sportfish Restoration and Marine Resource Management" were provided to students. These outreach events highlighted the importance of coastal resources and all facets of marine resource protection. Approximately 52 students attended Marine Fisheries Division presentations.

Finally, project staff led numerous workshops and speaking engagements throughout the state, as well as informational tours and talks at the Marine Fisheries Office (Table 11.2). These talks and tours reached all target audiences, especially the business community, teachers and students. Audiences learned how to become active participants in the fisheries management process, through public informational hearings and FAC Meetings.

## JOB 12: MARINE FISHERIES GIS

## GOAL

To maintain a geographic information system (GIS) of Project data to support map applications and geospatial analyses, assist with planning and executing Connecticut DEEP Marine Fisheries Division (MFD) surveys that support sport fish restoration goals, help people visualize the spatial extent of MFD project sampling efforts, assist in evaluating the effects of fishing and environmental conditions on the distribution and abundance of living resources in Long Island Sound, evaluate effects of marine spatial planning projects on living marine resources and fisheries in Long Island Sound, and improve coordination with other agencies.

## OBJECTIVES

1) Provide GIS-compatible, or GIS-ready, datasets and geo-referenced layers of data collected through other Jobs of this Project that are sanctioned by the Marine Fisheries Division.
2) Provide maps and geospatial analyses of Marine Fisheries Division data or other information relevant to managing living marine resources in Long Island Sound.

## INTRODUCTION

In recent years, there has been an increased need for staff to use geospatial technology to map and analyze marine environmental or fisheries related information. Project staff have also experienced an increasing number of requests to provide geospatial data to others (intra-agency, inter-agency, NGOs, academic institutions, etc) for use in, for example, fisheries stock assessments, habitat assessments, environmental sensitivity maps, and public outreach efforts. Therefore, in 2012, a new job was created within the project to support this need for geospatial datasets, data layers, analyses and products. This report includes results from the fourth year of the Job (2015).

## METHODS

GIS work was accomplished using ESRI ArcMap software and extensions licensed by the Connecticut DEEP. Published layers comply with Department policy pertaining to GIS data. Custom scripts were developed using well established scripting utilities (e.g. Python, HTML, CSS, Javascript). Products designed for the Internet adhere to Agency requirements for Agency websites, pages and products. A number of the custom applications, scripts and tools created during earlier segments of the Job continue to be used as templates in subsequent years.

## RESULTS

GIS staff created map summaries of tautog (blackfish) catch and release tag data from volunteer anglers. The maps were useful in illustrating that the majority of tautog recaptured had been tagged in the same general area where they were released. Maps of tautog tagged and recaptured along the Atlantic Coast from MA to NC were produced (see next page) based on data the anglers submitted to the American Littoral Society (ALS) tagging database. A local angling group, Tautogers United, is cooperating with project staff in an effort to get more detailed movement data for tautog in Long Island Sound (LIS) to assist with Interstate Management efforts. As part of this effort, not only are the anglers reporting their tagging information to ALS but they are also submitting it to CT DEEP Marine Fisheries Division. This allows project staff to preserve tag and recapture locations with greater precision than in the ALS coast wide tagging database. Based upon the finer resolution in the LIS locations provided by Tautogers United anglers, an additional map of tautog tagged $(\mathrm{n}=352)$ and recaptured $(\mathrm{n}=13)$ in LIS was produced to show finer- scale movements.

Tautog released along CT shore by angler group, Tautogers United, after being tagged with an ALS tag (orange triangles) and the recapture locations of the tagged fish (green circles). The majority of the recaptured fish did not move very far. The lines and comment boxes highlight the four Tautogers United tagged tautog with notable movements.

Number of Tautog tagged and released based on ALS Tagging Database, 1982-2015

Number of tagged Tautog recaptured based on ALS Tagging Database, 1982-2015

Also as part of the effort to improve Interstate Management of tautog (blackfish), project staff conducted a spatial analysis of tautog recreational fishery data to assist stock assessment biologists determine appropriate regional boundaries for management areas along the coast.

The most recent (2015) ASMFC benchmark stock assessment suggested that tautog in CT versus NY waters of Long Island Sound (LIS) be managed as two separate stock units. Biologists were concerned about this approach since the majority of tautog in LIS appear to stay in LIS and should be assessed as one stock.

Based on data from the Marine Recreational Information Program (MRIP), magnitude of catch and harvest by distance from shore, as well as the location of sample sites (top right), were used to propose boundaries for a new Long Island Sound assessment area to include both CT and NY waters (bright green area in map, bottom right).

Job 12 Page 5

Marine Fisheries Division staff expanded the use of coast-wide angler catch data to map changes in the distribution of another recreationally important finfish using (GIS) ArcMap software. The status of the Black Sea Bass stock was in question as recreational catch data from the southern states showed the species declining in abundance while angler catch data from northern states were increasing. To make sense of this discrepancy, standardized recreational catch rates from all sites were averaged by their latitude and longitude for each year from 2004 to 2014 using spatial statistical tools in GIS. The DEEP biologists determined that the annual center of the coast-wide catch has moved northward each year from New Jersey toward the southern coast of Long Island Sound. On average the center of the catch distribution moved northward about 115 miles over ten years. This analysis quantified the shift, or possible expansion, in the range of Black Sea Bass along the coast which the biologists had previously only suspected had occurred. The coast-wide stock can now be more accurately assessed by mapping abundance and harvest geographically as well as through time.

This map illustrates the movement of the center of the annual recreational catch of Black Sea Bass along the northeastern coast of the United States, denoted by bright green circles. The northward change in latitude is most significant. Averaging latitude and longitude artificially places the symbols offshore even though all the data reflect near-shore catches (black dots).

Data from the Estuarine Seine Survey (Job 8 in this report) were used to generate GIS map layers of forage fish indices by site for 5 -year intervals. These layers were provided to NOAA's Center for Coastal Monitoring and Assessment for use in their Long Island Sound Environmental Sensitivity Index (ESI) mapping project.

The Estuarine Seine Survey defines forage fish as short-lived, highly fecund species that spend the majority of their life cycles inshore where they are common food items for piscivorous fish. The index reflects relative abundance of the four most common forage species captured in this survey: Atlantic silversides, striped killifish, mummichog, and sheepshead minnow.

In these maps (left panel), red dots represent sites with high forage fish abundance while orange dots represent moderate abundance and yellow dots represent low abundance.

The highest abundances of forage fish are typically in the east, although the more recent time periods show moderate abundances in the west as well

NOAA's Long Island Sound ESI Atlas will be used by NOAA's Office of Response and Restoration in their assessment and response following major storms or natural disasters. The current ESI Atlas was last updated over a decade ago.

CT DEEP Marine Fisheries biologists, working with the Stevens Institute and NOAA NMFS, developed a model to simulate potential impacts of climate change on the Sound's ecosystem, including the effects on fish habitat in time and area (link: http://longislandsoundstudy.net/wp -content/uploads/2013/08/Georgas-et-al-R-CE-33-NYCT-CR-FinalReport.pdf).

Project staff then conducted a spatial analysis of data generated by the model to show in greater detail the spatial distribution of potential changes to finfish habitat.

Fish species not subject to commercial or sport harvest were grouped into warm and cold guilds based on the water temperatures each species preferred. Temperature preference was determined by guild abundance patterns in the LIS Trawl Survey, 1992-2013 (Job 5). Cold guild species prefer water temperatures from 7.1C-15.4C, whereas warm guild species prefer water temperatures from 11.8C-22.1C.

The map panel (left) shows the spatial distribution of habitat suited to warm guild species in four time periods: (1) 1980-1990, (2) 1991-2001, (3) 2002-2012, and (4) a future probability projection of a time when $\mathrm{CO}^{2}$ will have doubled over current levels (a moderately conservative IPCC scenario).

The color ramps used in the maps go from blue to red and quantify the percentage of time the area is
suitable for warm-guild species. Blue areas are suitable for warm-guild species $0-20 \%$ of the time, green areas are suitable $20-40 \%$ of the time, yellow areas are suitable $40-60 \%$ of the time, orange areas are suitable $60-80 \%$ of the time, and red areas are suitable $80-100 \%$ of the time.

For the past three decades (the top three maps, previous page), the area less suitable for warmguild species (blue \& green) has been gradually shrinking. Whereas, in the future (bottom map, previous page), the majority of the Sound will probably be highly suitable for warm-guild species more than $70 \%$ of the time (orange \& red areas). This change in habitat distribution will allow many warm temperate Mid-Atlantic species to migrate into the Sound earlier and stay longer each year, increasing competition with currently abundant cold temperate New England species.

The citation for the climate model is: Georgas, Nickitas, Penelope Howell, Vincent Saba, Alan Blumberg, Philip Orton. 2016. Analyzing history to project and manage the future: Simulating the effects of climate on Long Island Sound's physical environment and living marine resources.
