## A STUDY OF MARINE RECREATIONAL FISHERIES IN CONNECTICUT

## Cover Photo: Fisheries Biologist (retired) Penny Howell holding an Atlantic cod caught during the April 2016 Long Island Sound Trawl Survey aboard the R/V John Dempsey.

After more than 38 years of service to the State, Penelope (Penny) Howell retired on March 1, 2017. Penny had a long and distinguished career with CT DEEP Fisheries Division's Marine Fisheries Program (formerly known as the Marine Fisheries Division).

Penny began her career with Marine Fisheries collecting biological data on scup (porgy) aboard commercial trawling vessels in Long Island Sound. She often recalled her experiences working alongside commercial fishermen as the first woman hired in the Division. She was an integral part of a study examining the effects of trawling on lobster and was a contributing author to the legislative report required by Special Act 83-29 of the CT General Assembly.

Another notable undertaking Penny took on early in her career was to help design and implement the Long Island Sound (LIS) Trawl Survey in 1984, the Marine Fisheries Program's largest and second-longest running project. The LIS Trawl Survey monitors the abundance of over 100 marine finfish species and provides invaluable data for species stock assessments and studies that focus on the effect of environmental changes on species composition.

Penny always felt strongly that the nearshore resources below the high tide line were of importance and in need of monitoring. To address that need, she developed a number of surveys to collect data on this essential habitat and the species that occupy it. This included the ongoing Estuarine Seine Survey (created in 1988) to document winter flounder spawning sites, among other things.

In the mid-90's, Penny was tasked with evaluating the white perch populations in the CT River. She developed a tagging study to document the species' population levels and movement in the river. The information collected helped develop the recreational and commercial harvest restrictions for white perch in CT.

With few resources, Penny established a horseshoe crab spawning survey along the Connecticut coast, enlisting the help of numerous volunteers, both from the public and scientific communities. These data were ultimately used to determine the commercial harvest quota for this species set in 2000 , as well as to help determine areas that should be closed to commercial harvest in an effort to protect the food source of endangered migrating shore birds.

Penny has an unparalleled ability to talk about science and marine fisheries assessment on a level that all could understand. She developed a number of games for students of all ages, which broke down the most complex of population estimation methods and made learning fun. Penny was a familiar face, representing the Department on numerous Atlantic States Marine Fisheries Commission (ASMFC) committees, presenting at many professional conferences and giving talks to public interest groups. Outreach and education efforts were a priority for Penny as she was always eager to engage the public and others to raise awareness of environmental and conservation issues.

Similarly, Penny's writing contributions spanned from describing intricate modeling methods for marine species stock assessment reports to publishing a number of articles in reputable, peer-reviewed journals such as the Journal of Shellfish Research, Transactions of American Fisheries Society, and Marine and Coastal Fisheries. For six years, Penny was also a contributing author and editor for the marine fisheries articles featured in Connecticut Wildlife magazine, highlighting Connecticut's marine species and the programs that monitor them.

For the last seven years of her career, Penny dedicated most of her time to the American lobster resource, serving as the State's representative on ASMFCs American Lobster Technical Committee. She stepped into management of the species just after the catastrophic die-off in Long Island Sound, helping to document the decline of the resource and the continued recruitment failure of the species in the Sound. Her first task was to manage a one million dollar study to
determine the cause of the large-scale mortalities of lobster, working with geneticists, pathologists, and a number of environmental researchers along the coast. One of the most notable findings from this work was documentation of the thermal stress point for lobster $\left(68^{\circ} \mathrm{F}\right)$. Having learned the biological threshold for the species, Penny worked to find ways to monitor the bottom temperatures in Long Island Sound, documenting the ongoing stressful conditions for lobster which have hampered the species' rebound. She also took the lead on evaluating the effects of changing environmental conditions on other notable species in the Sound, including winter flounder.

Penny established numerous professional relationships within CT DEEP, ASMFC, other State resource agencies, and the environmental community. As a highly respected scientist, Penny was always willing to help someone design a study, improve the way data were collected, or select the appropriate statistical test to analyze results.

Penny was a tremendous asset to the Department.
Although we will surely miss her, we sincerely wish her well in her retirement.

## JOB 1: MARINE ANGLER SURVEY

## GOAL

## To collect marine recreational angler fishing information in the boat mode through a voluntary catch card survey program.

## OBJECTIVES

Provide estimates of:

1) Length-frequency distribution of harvested black sea bass, bluefish, scup, winter flounder, summer flounder, tautog, striped bass, and weakfish.
2) Length-frequency distribution of discarded black sea bass, bluefish, scup, winter flounder, summer flounder, tautog, striped bass, and weakfish.
3) Targeted catch/effort of black sea bass, bluefish, scup, winter flounder, summer flounder, tautog and striped bass.
4) Percent of targeted trips by species.

## INTRODUCTION

CT DEEP has collected marine recreational fisheries information along the Connecticut coastline since 1979 under several state and federal programs. In 2013-2015, NMFS assumed full angler survey responsibility for the federal Marine Recreational Information Program (MRIP) while DEEP continued to manage the site registry. Beginning in 2014, the Marine Angler Survey shifted focus to collection of length frequency of both harvested and released fish to supplement the MRIP survey. Length frequency data that includes released fish are difficult to obtain through traditional access point intercept surveys such as MRIP, and is particularly important for effective stock assessments. In addition, this program is designed to better characterize the private boat mode which lands a substantial proportion of fish caught in Connecticut waters ( $85 \%$ in 2012).

## METHODS

Marine recreational fishing information was collected through a voluntary catch card program. Post-marked daily catch cards (Figure 1.1) were distributed to anglers departing and returning from selected private boat sites, previously identified are areas of high activity, to maximize catch card distribution. Boat-based anglers at these selected fishing sites were recruited by DEEP staff to voluntarily report their fishing trip effort information and collect length measurements on fish caught, including both kept and released fish (discards). Each participating boat angler or angler group was given a waterproof daily catch card, pencil, and measuring tape in addition to verbal instructions. Anglers were encouraged to mail the post-marked catch cards upon trip completion or leave them in designated drop-off-boxes installed at key fishing sites along the coast. Each card issued bears a unique identification number and all cards handed out to anglers were accounted for using the unique card ID number. As an incentive to maximize participation,
anglers entering their Conservation ID/Fishing License Number are eligible to win a raffle prize at the end of the year. Boat-based anglers were also interviewed when their fishing trips were completed to aid in data collection.

Anglers are asked to provide the following information:

- Date of Trip (mm/dd)/Trip Start Time (check box AM/PM)
- Conservation ID/Fishing License Number
- Primary Fish Targeted
- Secondary Fish Targeted
- Total Hours Fished (lines wet)
- Areas Fished (see map)
- Number of Anglers that Caught Fish
- Number of Anglers in Fishing Party
- Boat's Total Catch for Trip
o Total Number of Fish Caught and Disposition (Kept/Released)
- If No Fish Caught -Check Box
- Length of First 8 Fish Caught
o Common Fish Name, Length, Disposition (Kept/Released)
Anglers are instructed to measure each fish to the nearest $1 / 2$ inch (rounded down) and record its disposition by circling either Y (yes) or N (no) in the Kept column. Fishing boat vessel registration is also requested. All data are entered and stored in an electronic database.

## RESULTS AND DISCUSIION

CT DEEP staff completed 338 interviews and distributed 257 catch cards to boat based anglers (60 at eight launch sites along CT's coastline) in Connecticut. Four launch sites in the east and west were chosen along with a group of Fairfield County boat anglers (FCBA). A total of 172 catch cards were distributed to Fairfield county boat anglers, 34 distributed (provided) at western boat launches, 26 distributed at eastern launches and another 25 to eastern boat anglers. Sixtyfive cards were returned from western anglers (FCBA \& western launches) and 27 cards were returned from anglers in the east in 2016. A total of 92 cards were returned (36\%) with 291 anglers reporting their fishing trip activities in 2016. Of the 291 anglers, 227 (78\%) caught at least one fish. There was a total of 575 (40\%) fish kept and 857 (60\%) fish released, including 13 finfish species or species groups.

The catch data from eastern and western sites are examined separately to address concerns regarding differences in angler catches in the eastern versus western Long Island Sound which were not clear when coast-wide catches were grouped (Table 1.1). Catch and disposition of striped bass and summer flounder were similar between regions. Black sea bass and tautog were more prevalent in the east; scup and bluefish were more common in the west (Table 1.3).

Volunteer anglers measured a total of 1,432 fish in 2016 (Table 1.2). Targeted species (black sea bass, bluefish, scup, striped bass, summer flounder, and tautog) accounted for $80 \%$ of the measured catch in 2016.

## JOB 2: VOLUNTEER ANGLER SURVEY

GOAL
To enhance the fisheries management process by providing supplemental catch, effort and size composition data for several important recreational finfish species through a voluntary logbook program.

## OBJECTIVES

Provide estimates of:

1) Size composition for both kept and released bluefish, striped bass and other common species.
2) Catch frequency by trip for both kept and discarded fish.

## INTRODUCTION

The Connecticut Volunteer Angler Survey (VAS) began in 1979 with the primary purpose of supplementing the National Marine Fisheries Service, Marine Recreational Fishery Statistics Survey/Marine Recreational Information Program by providing additional length measurement data. The survey emphasizes measurements of fish that are released, which are under-reported in the federal surveys. The survey's initial objective was to collect marine recreational fishing information concerning finfish species with special emphasis on striped bass. In 1994, the collection of bluefish length measurements was added to the survey and in 1997, length data for other marine finfish were added.

## METHODS

The VAS is designed to collect trip and catch information from marine recreational (hook and line) anglers who volunteer to record their fishing activities in a logbook (Appendix 2.1). The logbook contains fields in which to record fishing effort, target species, fishing mode (boat and shore), area fished (subdivisions of Long Island Sound and adjacent waters), catch information concerning finfish kept (harvested) and released, and length measurements. Instructions for volunteers are provided on the inside cover of the postage paid logbook. Each participating angler is assigned a unique numeric code for confidentiality purposes. After the logbook data are entered into the survey database, logbooks are returned to each volunteer for their personal records. Furthermore, to improve communications with recreational anglers and to encourage more public participation, volunteers are notified of upcoming public hearings, including proposed and final changes in recreational fishing regulations.

In 2013, the VAS program was incorporated into the Atlantic Coastal Cooperative Statistics Program (ACCSP) Standard Atlantic Fisheries Information System (SAFIS) eLogbook application. Under the ACCSP eLogbook application, the VAS database was upgraded from the previous outdated software. The VAS logbook format was slightly modified so that the information collected would be compatible with ACCSP minimum data element standards (Appendix 2.1). Initially, one of the primary purposes of incorporating the VAS database into ACCSP SAFIS was to enable anglers to enter their own fishing information and compile their own
statistics using eLogbook. However, because of the unique geographic location of Connecticut's shoreline, marine anglers often fish over multiple areas crossing interstate and federal boundaries during a single trip. The eLogbook software did not allow entry of data from fishing areas outside of Connecticut's marine waters. Therefore, as in previous years, paper logbooks were distributed to survey volunteers and Marine Fisheries staff completed VAS data entry. The problem was resolved in 2014, but only a portion of the volunteers entered their own data in 2014 and 2015, with the remainder submitting paper logbooks.

Since the Survey began in 1997, the number of participants has ranged from 18 anglers participating in 1979 to 115 anglers in 1997. Advertising the VAS program through the annually published Connecticut Angler's Guide and on the agency web site (www.ct.gov/deep/fishing) has helped increase volunteer participation. The guide is distributed to all anglers who purchase a Connecticut fishing license and is also circulated by bait and tackle shops and other entities.

## RESULTS AND DISCUSSION

In 2016, a total of 32 anglers participated in the program, recording 827 trips for an average of 26 trips each. Fewer VAS anglers $28 \%$ (9) entered their own data through the eLogbook application on the ACCSP website (www.accsp.org) in 2016 than 2015 ( 22 anglers), which was the second year of the eLogbook program. Most of the anglers that entered their own data expressed favorable comments toward the SAFIS eLogbook.

The private boat mode comprised the most trips (54\%) recorded, followed by shore based trips ( $44 \%$ ), see Job 3 for description of regular and enhanced shore sites. Of the total, $79 \%$ of the recorded trips were successful in catching fish. VAS anglers recorded catching 27 species including near shore species to open ocean pelagic species. This included seven principal recreational species currently under fisheries management plans which comprised $81 \%$ of the total catch. With the exception of several bait species and a few pelagic species, the release rate for nearly all species was $71 \%$ or greater.

VAS participants measured over $94 \%$ of their total catch ( 12,010 fish) and $97 \%$ of the seven principal species they caught $(9,752$ total). These data show a wide range in the release rate of the principal species. For example, $71 \%$ of scup caught were released while $83 \%$ of summer flounder caught were released. For bluefish, which has no minimum legal size, the release rate was $79 \%$. See Figure 3.1 through Figure- 3.7 for length frequency information on the 2016 VAS harvest and catch \& release data.

## CONCLUSIONS

VAS anglers provide valuable recreational fisheries catch data at a relatively low cost. In addition, the length data on released fish provided by this program is difficult or unattainable through conventional access point angler intercept surveys and is essential for effective assessment of the recreational fishery coastwide and in Connecticut. Any anglers interested in participating in the program can contact David Molnar at 860-434-6043, or e-mail address: david.molnar@ct.gov or writing to State of Connecticut, DEEP, Marine Fisheries Program, P.O. Box 719, Old Lyme CT 06371.

## MODIFICATIONS

None.

## ACKNOWLEDGEMENTS

We very grateful to all of the anglers who have participated in this survey. Without their cooperation and assistance, the VAS program would be not possible.

## Trip Header Record

The top of each page is for recording each trip's header information. In this section, make a new entry for each trip made. If you fill a logbook page before the trip is over, continue onto the next page. Use as many pages and books as necessary to record your fishing activity. If you have a multi-day trip, make only one entry for that trip.

Date Enter the date that your fishing trip occurred on.
Start Enter the time on a 24 hour clock (military time) that you Time started your fishing trip.

Mode Indicate the fishing mode by putting a check mark in the appropriate box. The Shore (Enhanced Site) option refers to the designated shore fishing sites along the Connecticut coast that allow for the harvest of smaller select species. See the anglers guide for more information.

## Trip Effort Record

Enter the approprate fishing effort information for the fishing area.

| Fishing | Enter the code for the area in which you made your catch. |
| :--- | :--- |
| Area | Refer to the Fishing Area Chart on page iii for the appropriate <br> area code. If you fish in the race along the border |
|  | between area 6 and 147, please use area code $\mathbf{6 .}$ |
| Total Enter the total number of anglers that are in the fishing party. <br> Anglers  |  |
| Lucky | Enter the number of anglers that caught fish in the fishing |
| Anglers | party. |

## Trip Catch Record

Under each trip effort record are the associated catch records.

## Enter a catch row for each species, disposition (Kept/Released) and length.

If you caught more fish then rows provide, continue onto the next effort or page as necessary.
If you do not catch or harvest any fish, complete the trip header and effort information
(Date through Targeted Species 2).

Species Enter the species code from the Species Code List below. If the species is not listed, write in the species name.
$\mathbf{K} / \mathbf{R} \quad$ Indicate if the fish were kept or released by writhing K (Kept) or $R$ (Released). If you kept and released the same species indicate this by adding an additional row. If you kept and released the same species, complete two rows.
Length (in) Enter the length in inches of the fish. ROUND DOWN TO THE NEAREST HALF INCH. In previous years, the Volunteer Angler Survey requested rounding to the nearest half inch but rounding down helps produce more accurate data.
Quantity Enter the number of fish of that specific species, disposition (K/R), and length. If any of these fields change, create a new row. If additional rows are needed, continue onto the next page.

| Species Code List |  |
| :---: | :---: |
| Groundfish | Other Finfish continued |
| COD - Cod | TAUG - Tautog / blackfish |
| HADD - Haddock | TRIG - Triggerfish |
| POLL - Pollock | WEAK - Weakfish / squeteague / |
| Flounders | gray sea trout |
| FLUK - Summer flounder / fluke | Tuna / Large Pelagics |
| FLBB - Winter flounder / blackback | ALB - Albacore tuna |
| Other Finfish | BET - Big eye tuna |
| Other Finfish | BFT - Bluefin tuna |
| BLU - Bluefish | BON - Bonito |
| BSB - Black sea bass | LTNY - Little tunny |
| CUN - Cunner | SKJ - Skipjack |
| EEL - Eel, American | YFT - Yellowfin tuna |
| MEN - Menhaden / bunker | DOL - Dolphin fish / mahi-mahi |
| WPRC - Perch, white | WAH - Wahoo |
| SCUP - Scup / porgy | Sharks and Skates |
| SROB - Sea robins |  |
| HSHD - Hickory shad | DGSP - Dogfish, spiny |
| STB - Striped bass | DGSM - Dogfish, smooth |
|  | SKAT - Skate <br> SHBL - Shark, blue |

## JOB 3: ENHANCED OPPORTUNITY SHORE FISHING PROGRAM

## GOAL

To maintain and improve the fishing experience, opportunity and quality of access to public trust marine fisheries resources in Connecticut especially in urban areas, while maintaining marine fish conservation objectives.

## OBJECTIVES

1. Preserve the quality of shore fishing opportunity for species whose management is heavily minimum size dependent, while also meeting fishery management plan conservation objectives.
2. Collect data from the designated enhanced shore fishing sites necessary to gauge the biological and social impact of enhanced opportunity and whether fishery management plan harvest targets are still being met.
3. Create an "adopt-a-shore-site" relationship with tackle shops that are located near specific sites to help maintain and manage locations.
4. Establish contacts with local officials of town-owned sites especially within urban areas to increase awareness and appreciation of quality shore based recreational fishing opportunity in their community.
5. Increase public awareness of the sites to encourage activity by increasing communication with tackle shops and anglers.

## INTRODUCTION

DEEP Marine Fisheries has identified the need to enhance fishing opportunity for shore based anglers. To meet this need, the agency designated shore based fishing sites (see Appendix 8.1) which allowed for less restrictive fishing regulations. Anglers fishing from designated enhanced opportunity shore fishing sites in 2016 were allowed to harvest scup at 9 inches minimum length (vs. 10.5 inches in other private fishing modes and 11 inches for party/charter modes) and summer flounder at 16 inches (vs 18 inches for other modes). The smaller minimum sizes were adopted out of concern that shore anglers were taking a disproportional share of the conservation burden associated with the increased minimum sizes adopted in response to the harvest limits established under the joint ASMFC/MAFMC fishery management plans for these species. In order to ensure that these less restrictive regulations meet the required conservation of the fishery management plan, The Atlantic States Marine Fisheries Commission (ASMFC) Summer Flounder, Scup and Black Sea Bass Management Board requested that DEEP monitor of the enhanced shore fishing sites to provide additional catch information.

A voluntary daily angler catch card program was developed to collect fishing trip and catch information, including length measurements of harvested and released (discarded) fish from recreational anglers at the enhanced shore fishing sites. Collecting length measurement data, especially on discarded fish, is extremely difficult to obtain through traditional access point angler
intercept surveys (e.g. MRIP). In past years, such length data has been successfully collected utilizing volunteer anglers to report their fishing trip information through a logbook survey (VAS, Job 2) and this program was used as a template for the more extensive catch card program (see Appendix 3.2).

## METHODS

Five assignment zones for sampling were established comprising a total of 39 of the 46 Enhanced Shore Fishing Sites from Stonington to Norwalk (Figure 3.1). For each assignment, the zone, time of day (am or pm), starting site and direction of travel was randomly selected using the SAS 'ranuni' function. Upon arriving at a site, the creel agent would record:

- Date and time of creel agent arrival
- Weekend or weekday
- Site name
- Initial count of angler(s)
- Arrival and departure time of additional anglers
- Date and time of creel agent departure

Each angler was asked to participate in an angler survey to provide fishing effort and catch information. If they agreed, the creel agent would perform a partial trip interview. The following questions were asked:

- What time did you start fishing?
- Have you been interviewed by this program already this year?
- What species are you fishing for?
- How many times do you go saltwater fishing per year?
- Of those, what percent are from shore?
- Are there any comments you would like to make about shore fishing in CT (pro's or con's).
- Have you caught any fish yet on this trip? If yes, how many fish of each species did you catch?

All fish caught while the creel agent is on site are measured and recorded. To capture the remaining catch and effort information, each participating angler was provided with a waterproof daily catch card, pencil, measuring tape, and verbal instructions by DEEP staff. Anglers were asked to fill out the following (data fields):

- Conservation identification number (fishing license number)
- Primary target species
- Secondary target species
- Total hours spent fishing
- Date ( $\mathrm{mm} / \mathrm{dd} / \mathrm{yy}$ )/start time (check box AM/PM)
- Total number of fish kept and released by species
- Length measurements for the first seven fish caught.

Anglers were encouraged to mail in the post-marked catch card or deposit it into designated drop-off-boxes installed at fishing sites upon trip completion. Also, questions concerning the survey could be answered by contacting the DEEP Marine Headquarters office.

## RESULTS AND DISCUSSION

Catch cards that were distributed to shore anglers were categorized by identification number, date, and enhanced shore fishing site code. From May through December 2016 there were a total of 76 assignments (Table 3.1) attributed to500 sites sampled (Table 3.2) in four zones. The largest number of intercepts and interviews occurred in June (Table 3.3).

A total of 874 catch cards were distributed to anglers at enhanced shore fishing sites and 308 (35\%) were returned. The reported catch included 18 species/taxonomic groups totaling 1,014 fish (Table 3.4) similar to the total for partial trip interviews as described in methods. The majority of the fish ( $71 \%$ ) were released due to regulatory discard or undesirable catch. The total harvest reported was 297 fish comprised of 11 species.

## Length Information

Each individual angler reported the common name(s) of the first seven fish captured, regardless of species and size. A total of 515 fish measurements by anglers and 409 fish measurements by agents were received, comprising 20 species (Table 3.5). Scup, sea robin, bluefish and striped bass were the most frequently harvested species measured by anglers (Figure 3.1), and comprised $69 \%$ of the total measured catch.

## Enhanced shore fishing

Although sample sizes are small, data gathered from this program indicate that having a minimum length of 9 inches at the Enhanced Sites improved the success rate for shore based scup anglers by $45 \%$ compared to anglers complying with the previously higher legal minimum length of 10 inches required at other shore locations. This increase is a near doubling of the $21 \%$ recorded in 2014, which was the first year of the program. Shore-based summer flounder anglers improved their success rate by $66 \%$ compared to anglers complying with legal minimum length requirements, similar to the $29 \%$ increase recorded in 2014. The success rates for each species were calculated using the length frequencies of kept fish from the returned catch cards. Specifically, the proportion of scup harvested between 9 and 10 inches and the proportion of summer flounder harvested between 16 and 18 inches.

## MODIFICATIONS

No modifications are expected.

## JOB 5: LONG ISLAND SOUND TRAWL SURVEY (LISTS)

## CRUISE RESULTS FROM THE 2016 <br> SPRING AND FALL SURVEYS

## STUDY PERIOD AND AREA

The Connecticut DEEP Marine Fisheries Program completed the thirty-third year of the Long Island Sound Trawl Survey in 2016. The Long Island Sound Trawl Survey (LISTS) encompasses an area from New London to Greenwich, Connecticut and includes waters from 5 to 46 meters in depth in both Connecticut and New York state waters. Typically, Long Island Sound (LIS) is surveyed in the spring, from April through June, and during the fall, from September through October. This report includes results from the 2016 spring and fall sampling periods and provides time series information since the commencement of the survey in 1984.

## GOAL

To provide long term monitoring of abundance, biomass and size composition of marine fishery resources along with environmental parameters, in order to evaluate the effects of fishing and environmental conditions on the distribution and abundance of living resources in Long Island Sound.

## OBJECTIVES

1) Provide annual indices of counts and biomass per standard tow for 40 common species and age-specific indices of abundance for winter flounder, tautog, scup, summer flounder, bluefish (Age $0,1+$ ) and weakfish (Age $0,1+$ ).
2) Provide length-frequency distributions of bluefish, scup, summer flounder, winter flounder, tautog, striped bass, weakfish, black sea bass, and other ecologically important species.
3) Provide annual total counts and biomass for all finfish species taken and annual total biomass for all common macro-invertebrate species taken.
4) Provide species list for LIS based on LISTS sampling, noting the presence of additional species from other sampling conducted by the Marine Fisheries Programs.
5) Provide fishery independent survey data to cooperative state researchers or agencies, such as the National Marine Fisheries Service (NMFS), Atlantic States Marine Fisheries Commission (ASMFC), New England and Mid-Atlantic Fishery Management Councils (NEFMC and MAFMC, respectively), and researchers associated with state or local universities

## INTRODUCTION

The Long Island Sound Trawl Survey (LISTS) was initiated in 1984 to provide fishery independent monitoring of important recreational species in Long Island Sound (LIS). A stratified-random design based on bottom type and depth interval was chosen and 40 sites were sampled monthly from April through November to establish seasonal patterns of abundance and distribution. Seven finfish species were initially of primary interest: bluefish, scup, striped bass, summer flounder, tautog, weakfish, and winter flounder. Length data for these species were collected from every tow; scup, tautog, and winter flounder were sampled for aging. Lobster were also enumerated and measured from every tow. All fish species were identified and counted.

Since 1984, several changes have been incorporated into the Survey. In 1991, the sampling schedule was changed to a spring/fall format, although sampling is still conducted on a monthly basis (April - June, September, and October). Beginning in 1992, species were weighed in aggregate with an onboard scale to provide indices of biomass. Furthermore, more species have been sampled for lengths, such as windowpane and fourspot flounders, and important forage species such as butterfish, long-finned squid, and several herring species. By 2003, the list of species measured expanded to 20 finfish species and two invertebrate species (lobster and long-finned squid), plus rarely occurring species. Beginning in 2014, lengths were collected from all finfish species on each tow. In addition, at various times during the time-series, age structures were collected from bluefish, menhaden, tautog, scup, winter flounder, weakfish or summer flounder. All of these changes serve to improve the quality and quantity of information made available to fishery managers for local and regional assessment of stock condition, and to provide a more complete annual inventory of LIS fishery resources.

## METHODS

## Sampling Design

LISTS is conducted from longitude $72^{\circ} 03^{\prime}$ (New London, Connecticut) to longitude $73^{\circ}$ 39' (Greenwich, Connecticut). The sampling area includes Connecticut and New York waters from 5 to 46 m in depth and is conducted over mud, sand and transitional (mud/sand) sediment types. Sampling is divided into spring (April-June) and fall (Sept-Oct) periods, with 40 sites sampled monthly for a total of 200 sites annually. The sampling gear employed is a 14 m otter trawl with a 51 mm mesh codend (Table 5.1). To reduce the bias associated with day-night changes in catchability of some species, sampling is conducted during daylight hours only (Sissenwine and Bowman 1978).

LISTS employs a stratified-random sampling design. The sampling area is divided into $1.85 \times 3.7 \mathrm{~km}$ ( $1 \times 2$ nautical miles) sites (Figure 5.1), with each site assigned to one of 12 strata defined by depth interval ( $0-9.0 \mathrm{~m}, 9.1-18.2 \mathrm{~m}, 18.3-27.3 \mathrm{~m}$ or, $27.4+\mathrm{m}$ ) and bottom type (mud, sand, or transitional as defined by Reid et al. 1979). For each monthly sampling cruise, sites are selected randomly from within each stratum. The number of sites sampled in each stratum was determined by dividing the total stratum area by $68 \mathrm{~km}^{2}$ ( 20 square nautical miles), with a minimum of two sites sampled per stratum (Table 5.2, Gottschall et al. 2000). Discrete stratum areas smaller than a sample site are not sampled.

## Sampling Procedures

Prior to each tow, temperature $\left({ }^{\circ} \mathrm{C}\right)$ and salinity (ppt) were measured at 1 m below the surface and 0.5 m above the bottom using a YSI model $30 \mathrm{~S}-\mathrm{C}-\mathrm{T}$ meter. Water was collected at depth with a five-liter Niskin bottle, and temperature and salinity were measured within the bottle immediately upon retrieval.

The survey's otter trawl was towed from the 15.2 m aluminum R/V John Dempsey for 30 minutes at approximately 3.5 knots, depending on the tide. At completion of the tow, the catch was placed onto a sorting table and sorted by species. Finfish, lobsters and squid were counted and weighed in aggregate (to the nearest 0.1 kg ) by species with a precision marine-grade scale ( $30 \mathrm{~kg},+/-10 \mathrm{gm}$ capacity). Catches weighing less than 0.1 kg were recorded as 0.1 kg . During the initial two years of the survey ( $1984 \& 1985$ ), lobsters were the only invertebrates recorded. Squid abundance has been recorded since 1986. Since 1992, additional invertebrate species have been weighed in aggregate, and some have been counted. The complete time series of species counted and weighed in the survey is documented in Appendix 5.4.

For finfish species, lengths were recorded to the centimeter as either total length or fork length (e.g. measurements from 100 mm to 109 mm were recorded as 10 cm ) and entered in the database as 105 mm (Table 5.3). Lobsters were measured to 0.1 mm carapace length. Squid were measured using the mantle length ( cm ), horseshoe crab measurements were taken using prosomal width (cm) and whelk (knobbed and channeled) shell widths were measured in millimeters.

The number of individuals measured from each tow varied by species, the size of the catch and range of lengths (Table 5.3). If a species was subsampled, the length frequency of the catch was determined by multiplying the proportion of measured individuals in each centimeter interval by the total number of individuals caught. Some species were sorted and subsampled by length group so that, for example, all large individuals were measured and a subsample of small (often young-of-year) specimens was measured. All individuals not measured in a length group were counted. The length frequency of each group was estimated as described above, i.e. the proportion of individuals in each centimeter interval of the subsample was expanded to determine the total number of individuals caught in the length group. The estimated length frequencies of each size group were then appended to complete the length frequency for that species. This procedure was often used with catches of bluefish, scup, and weakfish, which were usually dominated by young-of-year or discrete age/length classes.

Bluefish, menhaden, scup, summer flounder, tautog, weakfish (ageing was discontinued in 2013) and winter flounder were sampled for age determination (Table 5.3). The target number of age samples (otolith) for bluefish were 50 from the spring period (defined by ASMFC Bluefish Technical Committee as Jan-July) and 50 from the fall period (August-December). However, bluefish catches are hard to predict so the number of age samples varied greatly; sometimes more than the target number was collected solely from LISTS samples but other times LISTS samples needed to be augmented with samples from the recreational fishery to meet the target number. Sufficient numbers of bluefish age samples from LIS would also make it possible to develop an LIS-specific age key, so bluefish age samples were sometimes still collected even after the target number was reached. Subsamples of scup, stratified by length group, were measured to the nearest mm (fork length) and scales from each individual were taken for ageing.

Scup scales were removed posterior to the pectoral fin and ventral to the lateral line. The scales were pressed onto plastic laminate with an Ann Arbor roller press to obtain an impression of the scale, which was then viewed with a microfiche reader at 21x. Scales were also taken from all summer flounder greater than 59 cm . At least 15 scales were removed from the caudal peduncle area. These scales were pressed and aged to supplement the NMFS age key and were also included in the formulation of LISTS summer flounder catch-at-age matrix (see below). Subsamples of winter flounder, stratified by length group and area (as listed in bottom of Table 5.3), were iced and taken to the lab where they were measured to the millimeter (total length), weighed (gm) and sexed. Their maturity stage was determined (NMFS 1989), and otoliths were collected for age determination later. Amendment 2 of the ASMFC Atlantic menhaden Fishery Management Plan introduced a requirement of 10 fish for age samples per 300 metric tons landed in the commercial bait fishery to support improved stock assessments. Connecticut has such a small menhaden commercial fishery that one 10 -fish sample would suffice. The same size/age component of the menhaden population taken in the commercial fishery was available to LISTS so menhaden scales were collected during LISTS sampling; 216 menhaden age samples were taken in 2016. LISTS age samples of menhaden provide one of the few fishery independent sources of age data for adult menhaden in northern waters and are therefore valuable for stock assessments. Menhaden fork length (mm), and sex were recorded and scales were taken about mid-body (lateral line) and below the insertion of the dorsal fin. The ASMFC Tautog Fishery Management Plan (FMP) requires CT DEEP to collect a minimum of 200 age structures per. Due to the low numbers of tautog caught in LISTS in recent years (less than 250 fish), age structures were collected from most tautog taken in LISTS. Tautog were iced and taken to the lab, where their total length (mm), sex, and total weight (gm) were recorded and age structures were collected. LISTS has used opercula to age tautog since 1984 (Cooper 1967). The ASMFC Tautog Technical Committee requested that states collect paired age structures for comparison studies; therefore, LISTS began collecting tautog otoliths in addition to opercula in 2012. Results from an ASMFC Tautog Ageing Workshop in May 2012 indicated there was no clear benefit to switching from opercula to otoliths for Connecticut, so otoliths were collected (minimum of 50 paired structures per ASMFC) and archived for potential use in the future. Subsequent to the 2012 workshop, a study conducted by Massachusetts Division of Marine Fisheries (Elzey and Trull 2016) showed tautog pelvic fin spine sections may be a better structure (easier to read and non-lethal to collect). In 2016, LISTS started to collect pelvic fin spines for tautog, archiving them for future ageing work.

In reports prior to 2001 , three species were not included in annual and seasonal totals: American sand lance, bay anchovy, and striped anchovy. These species, with the possible exception of striped anchovy, can be very abundant in Long Island Sound, but are not retained well in the otter trawl. Additionally, many of these fish are young-of-year and often drop out of the net as it is retrieved and wound on the net reel. For this reason they were not included in the list of species to be counted when LISTS was started in 1984. However, to document the occurrence of these species in LISTS catches, American sand lance was added in 1994, striped anchovy was added in 1996, and bay anchovy was added in 1998. Since 2001, adults of these three species have been included in the annual and seasonal totals and the young-of-year are listed if present in the year's catch but are not quantified (Table 5.15, Appendix 5.4). Young-ofyear for these three species are included in the database but are cataloged with a separate species identifier and quantities are considered estimates (Appendix 5.2).

Interactions with endangered species during the course of sampling are regulated by the by NOAA Greater Atlantic Regional Fisheries Office (GARFO) Protected Species Division. Sampling procedures have been modified in recent years to minimize the likelihood of injury to Atlantic sturgeon (a Federally listed endangered species since 2012). When sampling in a season and area where the chance of catching a sturgeon is high (based on historic LISTS catch) and water depth is greater than 27 m , gear retrieval speed is reduced to decrease the stress induced by rapid changes in pressure. When an endangered species is detected in the net, it is removed as quickly and carefully as possible. Subsequent handling and processing of endangered species adhere to the Reasonable and Prudent Measures as well as the Terms and Conditions spelled out in the ESA Section 7 Biological Opinion's Incidental Take Statement issued by NOAA for CT in January 2013 (http://www.greateratlantic.fisheries.noaa.gov/protected/section7/bo/actbiops/ usfws state fisheries_surveys_2013.pdf). Additionally, handling and processing of sturgeon follow protocols described in A Protocol for Use of Shortnose, Atlantic, Gulf, and Green Sturgeons (Kahn and Mohead. 2010. U.S. Dep. Commerce, NOAA Tech Memo, NMFS-OPR45, 62p., http://www.nmfs.noaa.gov/pr/pdfs/species/kahn_mohead_2010.pdf). Twelve (12) Atlantic sturgeon were captured on eight (8) of the 196 tows completed in 2016. No other protected species were encountered. All interactions with endangered species are detailed in Appendix 5.5.

## Data Analysis

## Indices of Abundance: Annual Mean Count and Weight per Tow

To evaluate the relative abundance of common species, an annual spring (April - June) and fall (September - October) geometric mean number per tow and weight per tow (biomass, kg ) was calculated for the common finfish and invertebrate species. To calculate the geometric mean, the numbers and weight per tow were $\operatorname{logged}\left(\log _{e}\right)$ to normalize the highly skewed catch frequencies typical of trawl surveys:

$$
\text { Transformed variable }=\ln (\text { variable }+1)
$$

Means were computed on the log scale and then retransformed to the geometric mean:

$$
\text { geometric mean }=\exp (\text { mean })-1 .
$$

The geometric mean count per tow was calculated from 1984-2016 for 38 finfish species, lobster, and long-finned squid (1986-2016). The geometric mean weight per tow was calculated using weight data collected since 1992 for the same species, plus an additional 13 invertebrates.

For the seven finfish species that were measured on every tow in the time-series (bluefish, scup, striped bass, summer flounder, tautog, weakfish, and winter flounder), biomass indices were calculated for the years 1984-1991 by using length/weight equations to convert length frequencies to weight per tow. Bluefish, scup, weakfish and winter flounder lengths were converted using equations from Wilk et al. (1978); striped bass conversions were accomplished using an equation from Young et al. (1994); summer flounder and tautog conversions were accomplished using equations developed from LISTS data from 1984-1987 and 1984-1996 respectively.

## Indices of Abundance: Indices-at-Age and Age Group

Annual age specific indices (indices-at-age matrices) were calculated for scup, striped bass, summer flounder, winter flounder and tautog. The age data used to calculate the indices came from three sources: striped bass ages were derived using the von Bertalanffy (1938) equation; summer flounder age-length keys were obtained from the NMFS Northeast Fisheries Science Center spring and fall trawl surveys combined with LISTS ages ( $>59 \mathrm{~cm}$ ); scup, winter flounder and tautog age-length keys (in 1 cm intervals) were obtained directly from LISTS. Since fish growth can fluctuate annually as a function of population size or other environmental factors, a year and season specific age-length key was used wherever possible. Once lengths had been converted to age, the proportion at age was multiplied by the abundance index of the appropriate season to produce an index of abundance at age.

Recruitment (young-of-year) and age $1+$ (all fish age one and older) indices were calculated for bluefish and weakfish by using observed modes in the LISTS length frequencies to separate the two groups.

The specific methods used to calculate indices-at-age for each species were as follows:

- Bluefish. Age samples (otoliths) were taken from 330 bluefish, nine (9) from the spring period and 321 from the fall period. Of the samples taken in the spring, one was obtained from a demonstration tow not conducted as part of the LIS Trawl Survey. The majority of the fall samples were obtained from LISTS (213 fish), but a significant number were also collected from headboat ( 108 racks). In 2012 a coast wide biological sampling program was initiated through ASMFC Addendum 1 of the bluefish management plan. Since there are only five years of data from the northeast, there are still limited results available at this time. Therefore, the method of using modes observed in the fall length frequencies to separate bluefish into age 0 and age $1+$ groups, and calculating a geometric mean catch per tow for each group (Table 5.22) was continued through 2016. Comparison of the mean lengths-at-age reported for young-of-year and age 1 bluefish in the New York Bight (Chiarella and Conover 1990) and LIS (Richards 1976) with LISTS length frequencies suggests that bluefish can easily be identified as either age 0 (snapper bluefish) or adults (age 1+). Richards (1976) and Chiarella and Conover (1990) determined that most bluefish less than 30 cm are age 0 . A discontinuity in the LISTS fall length frequencies occurs most years between 26 cm and 39 cm (Table 5.42). Therefore 30 cm was determined to be a suitable length for partitioning age 0 and age 1 fish. With the addition the biological sampling programs along the coast, a regional northeast key is being compiled through ASMFC.

Prior to 2012, there was limited bluefish ageing in the northeast. Although North Carolina state biologists have aged bluefish for some time, their age keys were not used to age Long Island Sound bluefish because North Carolina mean lengths-at-age are not consistent with modes observed in Long Island Sound bluefish length frequencies. This difference suggests that growth may vary by region, or that early and late spawned bluefish may be differentially distributed along the coast (Kendall and Walford 1979).

- Scup. Scales from 832 scup were collected in 2016; 447 from the spring cruise and 385 from the fall cruise. An index-at-age matrix was developed for 1984-2016 using spring
(May-June only) and fall (September-October) LISTS data (Table 5.23). April data was omitted since very few scup are taken during the month. A total of 14,471 scup aged between 1984 and 2016 were used to make year and season specific age-length keys (1 cm intervals). In the relatively few instances when the season/year specific key failed at a given 1 cm length interval, a three-year pooled key was used to determine the age. Three-year pooled keys were calculated using the years preceding and following the "run" year. For the terminal year, only two years were used for the pooled key. Indices-at-age were computed for both spring and fall each year. Since very few scup older than age 9 are taken (less than $4 \%$ in any given year), an age $10+$ group is calculated by summing indices for ages 10 and up. To represent the full adult portion of the population an age $2+$ index is calculated by summing the indices for ages 2 through $10+$.
- Striped bass. To approximate the ages of striped bass taken in the spring survey (Table 5.24), the average of the Chesapeake Bay and Hudson River striped bass von Bertalanffy parameters ( $\mathrm{L}_{\max }=49.9 \mathrm{in}, \mathrm{K}=0.13, \mathrm{t}_{\mathrm{o}}=0.16$, Vic Crecco, pers. comm.) were used in the rearranged von Bertalanffy equation:

$$
t=(1 / K) *\left(-\log _{e}\left(\left(L_{\max }-L_{t}\right) / L_{\max }\right)\right)+t_{0}
$$

Since this equation estimates age $t$ as a fraction of a year, the estimates were rounded to the nearest year (e.g. age $3=$ ages 2.5 to 3.4 ). A spring catch-at-age matrix was developed for 1984 through 2016 by apportioning the spring index by the percentage of fish at each age (Table 5.25).

- Summer flounder. The year and season specific age-length keys ( 1 cm intervals) used to age LISTS catches were provided by NMFS from their spring and fall trawl surveys. These keys were supplemented with fish caught and aged by LISTS (typically 60 cm and over). LISTS also provides the age data from these fish (> 60 cm ) to NMFS. As in 2015, LISTS staff decided to also collect representative scale samples from smaller fluke in 2016 in the effort to eventually create an LIS-specific age-key. Until there are sufficient age samples to create the LIS-specific age-key, an age-key will be constructed using both LISTS and NMFS age data. In 2016, 282 summer flounder were aged: 166 from the spring $(10>59 \mathrm{~cm})$ and 116 from the fall $(6>59 \mathrm{~cm})$. Since 2001, whenever the season/year specific key failed at a given 1 cm length interval a pooled year key using only adjacent years was used (Gottschall and Pacileo 2002).
- Tautog. An index-at-age matrix was developed for 1984-2015 using all survey months (Gottschall and Pacileo 2007) (Table 5.27). During 2016, age structures were collected from 276 tautog caught on LISTS: 231 collected in the spring and 45 collected in the fall. Ageing for 2006-2012 has been completed and preliminary ageing for 2013-2015 has been done. The index-at-age matrix will be updated for 2016 fish once the structures have been aged.
- Weakfish. Age 0 and age $1+$ indices were calculated for both spring (1984-2016) and fall surveys (1984-2009, 2011-2016) (Table 5.28). Since few weakfish are taken in April, the spring geometric mean was calculated using only May and June. All weakfish taken in spring are assumed to be age $1+$. Similar to bluefish, the fall age 0 and $1+$
indices were calculated by using length frequencies to separate the catch. Since a break in the fall length frequencies generally occurs between 24 and 32 cm each year (Table 5.57), weakfish less than 30 cm are considered to be age 0 while those greater than or equal to 30 cm are ages $1+$. Ageing for weakfish was discontinued in 2013.
- Winter flounder. An index-at-age matrix was developed for 1984-2016 using April and May LISTS data (Table 5.29). June data were not used since length frequency data suggest that many adult winter flounder have left the Sound by this time (an exception was made for 1984, the first year of LISTS, because very few samples were taken in the spring months). A total of 23,697 winter flounder aged between 1984 and 2015 were used to make year and region (east of Stratford Shoal, west of Stratford Shoal) specific age-length keys in 1 cm intervals. Similar to scup and summer flounder, three year pooled keys using only the adjacent years (two years for the terminal year runs) were used to assign ages if year specific keys were not available. As 2016 age samples ( $\mathrm{n}=525$ ) have not been aged, a pooled key of the previous two years was used.

Each flounder aged as described above was also assessed for maturity stage by sex following Burnett (1989). CT DEEP staging of winter flounder was verified in a cooperative study with NMFS in 2009-2010 (Gottschall and Pacileo 2011). The percentage of male and female fish in each centimeter length group that was sexually mature (ripe, resting, or spent) was calculated in order to determine the length group at which $50 \%$ was mature each year.

## Species Richness by Group

The Long Island Sound Trawl Survey monitors species richness using groups of species classified as either cold temperate or warm temperate. For the purposes of tracking species richness, American sand lance, bay anchovy, and striped anchovy were omitted (see Sampling Procedures section). All other finfish species captured in LISTS were divided into groups based on their temperature preferences and seasonal spawning habits as documented in the literature (Collette and Klein-MacPhee 2002, Murdy et al. 1997). Species in the cold temperate group prefer water temperatures below $15^{\circ} \mathrm{C}\left(60^{\circ} \mathrm{F}\right)$, tend to spawn at the lower end of their temperature tolerance range, and are more abundant north of Long Island Sound than south of New York. Species in the warm temperate group prefer warmer temperatures $\left(11-22^{\circ} \mathrm{C}\right.$ or $\left.50-77^{0} \mathrm{~F}\right)$, tend to spawn in the upper range of their temperature tolerance, and are more abundant south of the Sound than north of Cape Cod (Appendix 5.6). Species that are not tolerant of cold temperatures, are abundant only south of Chesapeake Bay but stray into northern waters mostly as juveniles, and spawn only in the mid-Atlantic Bight and south were placed into a separate group (subtropical) and were not included in the analysis because they are typically only present in the fall LISTS.

## Open Water Forage Abundance

A Long Island Sound open water forage index of abundance was compiled to measure the available food base which supports resident and migratory species within the Sound. This index is formulated as a biomass index that is assembled from 11 of the forage species that are most common in LISTS catches along with three other species that are considered forage at an early
life stage (young-of-year or YOY). The species used to generate the index are: Atlantic herring, long-finned squid, butterfish, alewife, blueback herring, American shad, hickory shad, menhaden, whiting, spotted hake, and red hake along with young-of-year scup, bluefish, and weakfish (Figure 5.16). The geometric mean biomass is calculated using the aggregate of these 14 species on a per tow basis and calculated using the same methodology as described above for individual species biomass indices.

## RESULTS AND DISCUSSION

## Overview of LISTS 2016 Spring and Fall Surveys

Each month of the survey, sampling aboard the R/V John Dempsey generally began in the east end of Long Island Sound and progressed westward. The April survey commenced on April 14, 2016, and continued until April 27 for a total of nine (9) days underway and 26 tows completed. May sampling started on May 19 and continued until June 6 with twelve (12) sampling days underway and 40 sites completed. June sampling began on June 16 and ended on June 30, taking eleven (11) days underway to complete the 40 sites. The Fall Survey commenced on September 8 and needed twelve (12) days underway to complete 40 tows. The 40 sites for October were also completed in thirteen (13) days (from Oct 11 - Nov 1). Thus, a total of 196 LISTS tows were completed in 57 days underway during the spring and fall 2016 surveys (Table 5.4), not including transit days or weather days.

Maps showing the sites selected versus the sites sampled during each month of sampling are provided in Figure 5.2 (April), Figure 5.3 (May), Figure 5.4 (June), Figure 5.5 (September) and Figure 5.6 (October). Within each figure the red bordered sites are the sites selected for the month and the solid blue dots indicate the actual sites sampled. If a site had to be relocated during sampling, an explanation of why it was moved is provided under the figure. Additional site/station information is provided in Table 5.5 (April), Table 5.6 (May), Table 5.7 (June), Table 5.8 (September) and Table 5.9 (October). These tables provide date of sample, time, tow duration, latitude/longitude, surface and bottom temperature and salinity, average tow speed, distance towed and approximate area swept for each tow.

Sometimes, a full 30 -minute tow cannot be completed. Typical reasons for short tows include lack of room because of observed pot gear set in the immediate area, a drop in speed due to entanglement with some object on the bottom (frequently derelict pot gear), or a complete stop in forward motion (submerged wreck or rock pile). Survey crew will often attempt to finish an interrupted tow by clearing the net (if needed) and resetting beyond the obstruction or observed gear. If this is not possible, a site may have to be moved to another site nearby with the same stratum (bottom type and depth). If the site was moved, the data from the initial site will not be used. Typically, a minimum of 15-20 minutes of tow time is required for a LISTS tow to be recorded. However, there are occasions when a tow with less than 15 minutes will be accepted, usually because there is no alternate site in the designated strata in the vicinity. Short tow information for each month in the 2016 survey is summarized in Table 5.10.

## Cooperative Sample and Data Collection

LISTS staff participate in cooperative efforts for sample collections, data requests, and special projects using survey personnel, equipment, and other resources. Most of these
cooperative efforts are with state researchers or agencies, the National Marine Fisheries Service, Atlantic States Marine Fisheries Commission, New England and Mid-Atlantic Councils, and researchers or graduate students associated with state or local universities. Table 5.11 illustrates many of the organizations that requested data in 2016, while Table 5.12 shows sample requests received and fulfilled. In recent years, many requests for samples have come from high schools, aquariums, or other educational organizations needing finfish and invertebrates for teaching purposes. Additionally, Fisheries Division staff often have sample or data requests for media or other public outreach events (see Job 11 of this report).

## Number of Species Identified

LISTS observed 55 finfish species in 2016 (Table 5.13). This included two new species for the survey: sand tiger shark (Carcharias taurus) and bluntnose stingray (Dasyatis say). A female sand tiger shark ( 153.5 cm TL, 21.8 kg ) was caught in October in the eastern sound, a few miles north of Mattituck, NY. The bluntnose stingray ( $51.5 \mathrm{~cm} \mathrm{TL}, 0.6 \mathrm{~kg}$ ) was also captured in October, about 3 miles south of Guilford, CT. From 1984 to 2016, LISTS has identified 111 finfish species (Appendix 5.1), averaging 58 species per year with a range of 43 to 70 species (Figure 5.7). In addition, a total of 39 types of invertebrates were collected in 2016 (Table 5.14). Most invertebrates are identified to species. However, in some cases, invertebrates were identified to genus or a higher level taxon.

## Total Catch

Appendix 5.4 presents a time series (1984-2016) of the finfish species collected each year and their respective rank by numbers. Annual total biomass of invertebrates is also included in this appendix (1992-2016), ranked by weight (kg). A total of 277,166 finfish weighing 28,495 kg were sampled in 2016 (Table 5.15). In the spring of 2016, a total of 173,041 finfish weighing $18,025 \mathrm{~kg}$ were sampled and a total of 104,124 finfish weighing $10,469 \mathrm{~kg}$ were sampled in fall of 2016 (Table 5.16). A total of $1,126 \mathrm{~kg}$ of invertebrates were taken in 2016 (Table 5.15). The total biomass of invertebrate catch taken in the spring of 2016 was 458 kg while a total of 668 kg of invertebrates were taken in fall (Table 5.17).

## Length Frequencies

Length frequency tables are provided primarily to give the reader an understanding of the size range of various species taken in LISTS. Lengths are converted to age frequencies for analysis of principal species such as scup, bluefish, striped bass, summer flounder, tautog, winter flounder, and weakfish. Changes such as an expansion in the size (age) range for some important recreational species are apparent in recent years including more large scup (Table 5.52-5.53), striped bass (Table 5.54-5.55), and summer flounder (Table 5.56-5.57).

Length frequencies were prepared for 22 species:

| alewife | spring and fall | $1989-2016$ | Table 5.30; |
| :--- | :--- | :--- | :--- |
| American shad | spring and fall | $1989-2016$ | Table 5.31; |
| American lobster | spring and fall (M\&F) | $1984-2016$ | Table 5.32-Table 5.35; |
| Atlantic herring | spring and fall | $1989-2016$ | Table 5.36; |
| Atlantic menhaden | spring and fall | $1996-2016$ | Table 5.37; |
| black sea bass | spring and fall | $1987-2016$ | Table 5.38, Table5.39 |

| blueback herring | spring and fall | $1989-2016$ | Table 5.40; |
| :--- | :--- | :--- | :--- |
| bluefish | spring and fall | $1984-2016$ | Table 5.41, Table 5.42; |
| butterfish | spring and fall | $1986-1990,1992-2016$ | Table 5.43; |
| clearnose skate | spring and fall | $1993-2016$ | Table 5.44, Table 5.45; |
| fourspot flounder | spring and fall | $1989-1990,1996-2016$ | Table 5.46; |
| hickory shad | spring and fall | $1991-2016$ | Table 5.47; |
| horseshoe crab | spring and fall (M\&F) | $1998-2016$ | Table 5.48, Table 5.49; |
| long-finned squid | spring and fall | $1986-1990,1992-2016$ | Table 5.50, Table 5.51; |
| scup | spring and fall | $1984-2016$ | Table 5.52, Table 5.53; |
| striped bass | spring and fall | $1984-2016$ | Table 5.54, Table 5.55; |
| summer flounder | spring and fall | $1984-2016$ | Table 5.56, Table 5.57; |
| tautog | spring and fall | $1984-2016$ | Table 5.58, Table 5.59; |
| weakfish | spring and fall | $1984-2016$ | Table 5.60, Table 5.61; |
| windowpane flounder | spring and fall | $1989,1990,1994-2016$ | Table 5.62, Table 5.63; |
| winter flounder | April-May and fall | $1984-2016$ | Table 5.64, Table 5.65; |
| winter skate | spring and fall | $1995-2016$ | Table 5.66. |

For the years where length data are available, length frequencies were prepared for the seasons or months for which the preferred indices of abundance and catch-at-age matrices are calculated; for some species length frequencies are provided for both seasons.

## Seasonal Indices of Abundance

The geometric mean count per tow was calculated from 1984-2016 for 38 finfish species plus lobster and long-finned squid (squid since 1986). All spring (April-June) and fall (September-October) data are used to compute the abundance indices presented in Tables 5.18 (spring) and 5.19 (fall), with the preferred seasonal index (for counts) denoted by an asterisk. Geometric mean biomass-per-tow indices have been calculated for 38 finfish and 15 invertebrate species (or species groups) since 1992, for both spring and fall (Table 5.20 and 5.21, respectively). Age specific indices of abundance were calculated for selected important recreational species, including scup, striped bass, summer flounder, and winter flounder (see below). Bluefish and weakfish recruitment indices were calculated using modal analyses of the length frequencies. For each of the 38 finfish species, plots including catch per tow in numbers and biomass in kilograms are illustrated in Figures 5.8 through 5.13. These figures also include plots of each of the age specific indices and recruitment indices mentioned above. Figure 5.14 provides plots of abundance (biomass) indices for crabs (lady, rock, spider; 1992-2016), American lobster (1984-2016), horseshoe crab (1992-2016), and long-finned squid (1986-2016).

## Indices of Abundance: Important Recreational Species

Spring and fall abundance indices are presented in Tables 5.18-5.19. Indices of abundance at age were also calculated for seven important recreational species: bluefish (Table 5.22), scup (Table 5.23), striped bass (Table 5.24 age frequency, Table 5.25 indices at age), summer flounder (Table 5.26), tautog (Table 5.27), weakfish (Table 5.28) and winter flounder (Table 5.29). Bluefish and striped bass indices-at-age are based on the fall and spring surveys, respectively, whereas winter flounder indices-at-age are based on only the April and May cruises of the spring survey. Summer flounder, scup and weakfish indices-at-age are calculated and presented separately for each season. Modal distributions were used to calculate recruitment
indices for bluefish and weakfish. Although age structures for bluefish are now being collected, it may take a few years before there is enough age data to construct a robust age key (see methods).

## Species Richness by Group

The number of cold temperate and warm temperate species captured in each tow was averaged by seasonal cruise (April-June and September-October) for each year from 1984-2016 as an indicator of annual biological diversity or species richness. Trends in these indicators were tested for statistical significance by regression analysis. Results (Figure 5.18) show that the average number of warm temperate species captured/tow in spring and fall cruises has increased ( $\mathrm{F}=32.2$ and 86.7 respectively, $\mathrm{p}<0.0001$ ); while the average number of cold temperate species has decreased, especially in spring ( $\mathrm{F}=52.5, \mathrm{p}<0.0001$ ) but also in fall cruises ( $\mathrm{F}=20.2$, $\mathrm{p}<0.0001$ ).

## MODIFICATIONS

An analysis of the 30+ year time series of LISTS catch at age data for winter flounder will be conducted during the next project segment to determine how project resources will be allocated with respect to winter flounder ageing. Although winter flounder otoliths were collected in 2016 using the standard procedures outlined in the Methods, ageing of the structures was not completed for this project year due to work force limitations. Given expected further attrition in staffing levels, Project staff have begun looking at whether or not to continue the labor-intensive process of collecting, processing and ageing 400-900 winter flounder otoliths each year given the other demands upon Project resources. One alternative course of action may be to reduce the number of winter flounder ageing samples collected and/or processed. Another option may be to use a LISTS time-series pooled age key to assign ages to winter flounder lengths. Additional options may be to obtain age keys from neighboring states or use a regional key as is done for other species (such as summer flounder). Since winter flounder abundance in Long Island Sound has been decreasing for some time now (more than a decade), there is no longer a substantial recreational (or commercial) fishery for it; therefore, Project resources may need to be allocated differently in the future.

| Totals | $\mathbf{7}$ | $\mathbf{1 0}$ | $\mathbf{1 2}$ | $\mathbf{1 1}$ | $\mathbf{4 0}$ |

Table 5.3. Length and age data collected in 2016.
In addition to the species listed below, other rarely occurring species (totaling less than 30 fish/year each) were measured. During 2016, twenty-seven other species were measured during LISTS sampling as either rarely occurring species or for other research related projects

| Species measured | Measurement | \# tows/day | \# fish measured |
| :---: | :---: | :---: | :---: |
| Alewife | FL (cm) | All | min of 15 / tow |
| American lobster | CL ( 0.1 mm ) | All | min of 50 / tow |
| American shad | FL (cm) | All | min of 15 / tow |
| Atlantic herring | FL (cm) | All | min of 15 YOY and min of 30 adults / tow |
| Atlantic menhaden | FL (cm) | All | min of 15 / tow |
| Atlantic sturgeon | FL (cm) | All | All |
| Blueback herring | FL (cm) | All | min of $15 /$ tow |
| Bluefish | FL (cm) | All | min of $30 \mathrm{YOY} /$ tow, all adults |
| black sea bass | TL (cm) | All | All |
| butterfish | FL cm) | All | min of 15 YOY and 15 adults / tow |
| cunner | TL (cm) | All | All |
| dogfish, smooth | FL (cm) | All | All |
| dogfish, spiny | FL (cm) | All | All |
| fourspot flounder | TL (cm) | All | min of $30 /$ tow |
| hake, red | TL (cm) | All | min of $30 /$ tow |
| hake, silver (whiting) | TL (cm) | All | min of $30 /$ tow |
| hake, spotted | TL (cm) | All | min of $30 /$ tow |
| hickory shad | FL (cm) | All | All |
| horseshoe crab | PW (cm) | All | All |
| northern searobin | FL (cm) | All | min of $30 /$ tow |
| moonfish | FL (cm) | All | min of $10 /$ tow |
| smallmouth flounder | TL (cm) | All | min of $10 /$ tow |
| striped bass | FL (cm) | All | All |
| striped searobin | FL (cm) | All | min of $30 /$ tow |
| scup | FL (cm) | All | min of 15 YOY and $30 /$ mode for age $1+$ |
| long-finned squid | ML (cm) | All | min of $30 /$ tow |
| summer flounder | FL (cm) | All | All |
| tautog | TL (cm) | All | All |
| weakfish | FL (cm) | All | min of $15 \mathrm{YOY} /$ tow, all adults |
| whelk, channeled | PW (mm) | All | All |
| whelk, knobbed | PW (mm) | All | All |
| windowpane flounder | TL (cm) | All | min of $50 /$ tow |
| winter flounder | TL (cm) | All | min of $100 /$ tow |
| winter skate | TL (cm) | All | All |

| Species aged | Structure | Subsample |
| :---: | :---: | :---: |
| bluefish | scales / otoliths | Collected each season. For each season, minimum of 50 scale and otolith samples collected from full length distribution. Spring collection may use other means of sampling to obtain the required minimum. |
| menhaden scup | scales <br> scales | Collected each season. For each season, minimum of 50 scale samples collected from full Collected every month. For each month scales are taken from the following: 3 fish $/ \mathrm{cm}$ $<20 \mathrm{~cm}$; $5 / \mathrm{cm}$ from $20-29 \mathrm{~cm}$; and all fish $>30 \mathrm{~cm}$. |
| summer flounder | scales | all fish $>=60 \mathrm{~cm}$ |
| tautog | opercular bones otoliths or pelvic fin rays | Collected from a minimum of 200 fish/year. collected from minimum 50 fish/year |
| weakfish | scales / otoliths | Ageing/collections discontinued in October 2014 |
| winter flounder | otoliths | Collected during April and May from two areas in the Sound: eastern-central and western. For each month and area, subsamples are taken as follows: in the eastern-central area 7 fish $/ \mathrm{cm}<30 \mathrm{~cm}, 14 / \mathrm{cm}$ from $30-36 \mathrm{~cm}$, all fish $>36 \mathrm{~cm}$. In the western area 5 fish / $\mathrm{cm}<30 \mathrm{~cm}, 10 / \mathrm{cm}$ from $30-36 \mathrm{~cm}$, all fish $>$ than 36 cm . |

Notes: $\min =$ minimum; $\mathrm{YOY}=$ young-of-year; $\mathrm{FL}=$ fork length; $\mathrm{TL}=$ total length; $\mathrm{CL}=$ carapace length; $\mathrm{ML}=$ mantle length; $\mathrm{PW}=$ prosomal width.

Table 5.4. Number of Long Island Sound Trawl Survey (LISTS) samples taken by year and cruise.
In 1984, thirty-five sites per monthly cruise from April through November were scheduled for sampling. Starting in 1985, forty sites per cruise were scheduled. In 1991, the Trawl Survey was modified to a spring (April - June) and fall (September - October) format--July, August and November sampling was suspended. In 1993 and 1994, an additional cruise of 40 sites was added to the fall period. The additional fall cruise was suspended in 1995. One hundred twenty tows were conducted in 2006 due to delays in rebuilding the main engine on the R/V John Dempsey (spring) and mechanical failure/overhaul of the hydraulic power take-off (fall). Delays in overhauling the transmission in the fall of 2008 resulted in missing September sampling. The June cruise and all of fall sampling in 2010 were canceled for an engine replacement in the $R / V$ John Dempsey. Due to delays in engine replacement, begun in 2010 but not completed until late April 2011, April sampling in 2011 was abbreviated.

| Year |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 5.5. Station information for LISTS April 2016.
Standard LISTS tows in the spring begin with SP and fall begins with FA. Latitude (N) and Longitude (W) are displayed in decimal degrees. Surface and bottom temperature and salinity are labeled as $S_{-}$and $B_{-}$, respectively. Area swept is estimated by assuming the effective sweep is $2 / 3 \mathrm{rds}$ of the footrope length.

| Sample Number | Date | Site Number | Bottom Type | Depth Interval | Time Start | Duration (min) | Latitude | Longitude | $\begin{aligned} & \text { S_Temp } \\ & \text { (sfc, C) } \end{aligned}$ | S_Salinity (sfc, ppt) | $\begin{aligned} & \hline \text { B_Temp } \\ & \text { (btm, C) } \end{aligned}$ | B_Salinity <br> (btm, ppt) | Ave Speed (knots) | $\begin{gathered} \text { distance } \\ (\mathrm{nm}) \end{gathered}$ | Area Swept (sq.nm) |

Table 5.8. Station information for LISTS September 2016.
Standard LISTS tows in the spring begin with SP and fall begins with FA. Latitude (N) and Longitude (W) are displayed in decimal degrees. Surface and bottom temperature and salinity are labeled as $S_{-}$and $B_{-}$, respectively. Area swept is estimated by assuming the effective sweep is $2 / 3$ rds of the footrope length.

| Sample Number | Date | Site Number | Bottom Type | Depth Interval | Time Start | Duration (min) | Latitude | Longitude | $\begin{gathered} \hline \text { S_Temp } \\ \text { (sfc, C) } \end{gathered}$ | S_Salinity (sfc, ppt) | $\begin{aligned} & \hline \text { B_Temp } \\ & \text { (btm, C) } \end{aligned}$ | B_Salinity <br> (btm, ppt) | Ave Speed (knots) | $\begin{gathered} \hline \text { distance } \\ (\mathrm{nm}) \end{gathered}$ | Area Swept (sq.nm) |

Job 5 Page 22

Table 5.9. Station information for LISTS October 2016.
Standard LISTS tows in the spring begin with SP and fall begins with FA. Latitude (N) and Longitude (W) are displayed in decimal degrees. Surface and bottom temperature and salinity are labeled as $S_{-}$and $B_{-}$, respectively. Area swept is estimated by assuming the effective sweep is $2 / 3$ rds of the footrope length

| Sample Number | Date | Site Number | Bottom Type | Depth Interval | Time Start | Duration (min) | Latitude | Longitude | $\begin{gathered} \hline \text { S_Temp } \\ \text { (sfc, C) } \end{gathered}$ | S_Salinity (sfc, ppt) | $\begin{aligned} & \hline \text { B_Temp } \\ & \text { (btm, C) } \end{aligned}$ | B_Salinity <br> (btm, ppt) | Ave Speed (knots) | $\begin{gathered} \text { distance } \\ (\mathrm{nm}) \end{gathered}$ | Area Swept (sq.nm) |

| FA2016041 | 10/11/2016 | 1840 | T | 1 | 16:31 | 23 | hang | strayed too far from tow path; tore up net |
| FA2016052 | 10/14/2016 | 1425 | M | 1 | 11:37 | 26 | hang | large tear in port wing; had to switch nets |
| FA2016064 | 10/20/2016 | 1118 | M | 1 | 8:16 | 26 | ran out of room | pots all around us |
| FA2016069 | 10/24/2016 | 1121 | M | 2 | 10:43 | 21 | speed drop | string of pot gear on port wing; substantial damage to net |

Table 5.11. Data requests by month.

Table 5.12. Sample requests by month.

| MONTH | ORGANIZATION OR PURPOSE |
| :---: | :---: |
| May |  |
| squid \& various finfish specimens for dissection class | Putnam High School |
| hermit crabs | UConn |
| variety of hardy fish \& invertebrates for "Stormwater Classroom" | East Lyme School System |
| variety of fish for x -ray of head structures for ageing manual | ASMFC |
| tautog tissue samples for DNA study | VIMS |
| channeled and knobbed whelk (conch) | NY DEC |
| June |  |
| channeled and knobbed whelk (conch) | NY DEC |
| tautog tissue samples for DNA study | VIMS |
| hermit crabs | UConn |
| September |  |
| channeled and knobbed whelk (conch) | NY DEC |
| October |  |
| squid \& various finfish specimens for dissection class | Putnam High School |
| channeled and knobbed whelk (conch) | NY DEC |
| stripers for PCB study | NY DEC |
| November |  |
| channeled and knobbed whelk (conch) | NY DEC |

Table 5.13. List of finfish species observed in 2016.
Fifty-five finfish species were observed in 2016. (Bold type indicates new species). Since 1984, one hundred-eleven species of finfish have been identified in LISTS (see Appendix 5.1 for the full list of species).

| Common Name | Scientific Name | Common Name | Scientific Name |
| :---: | :---: | :---: | :---: |
| anchovy, bay | Anchoa mitchilli | menhaden, Atlantic | Brevoortia tyrannus |
| anchovy, striped | Anchoa hepsetus | moonfish | Selene setapinnis |
| black sea bass | Centropristis striata | pinfish | Lagodon rhomboides |
| blue runner | Caranx crysos | pollock | Pollachius virens |
| bluefish | Pomatomus saltatrix | puffer, northern | Sphoeroides maculatus |
| butterfish | Peprilus triacanthus | ray, bluntnose stingray | Dasyatis say |
| cod, Atlantic | Gadus morhua | ray, roughtail stingray | Dasyatis centroura |
| cunner | T autogolabrus adspersus | rockling, fourbeard | Enchelyopus cimbrius |
| cusk-eel, striped | Ophidion marginatum | scad, rough | Trachurus lathami |
| dogfish, smooth | Mustelus canis | scup | Stenotomus chrysops |
| dogfish, spiny | Squalus acanthias | sea raven | Hemitripterus americanus |
| flounder, fourspot | Paralichthys oblongus | searobin, northern | Prionotus carolinus |
| flounder, smallmouth | Etropus microstomus | searobin, striped | Prionotus evolans |
| flounder, summer | Paralichthys dentatus | sennet, northern | Sphyraena borealis |
| flounder, windowpane | Scophthalmus aquosus | shad, American | Alosa sapidissima |
| flounder, winter | Pseudopleuronectes american | shad, hickory | Alosa mediocris |
| goosefish | Lophius americanus | shark, sand tiger | Carcharias |
| haddock | Melanogrammus aeglefinus | silverside, Atlantic | Menidia menidia |
| hake, red | Urophycis chuss | skate, clearnose | Raja eglanteria |
| hake, silver | Merluccius bilinearis | skate, little | Leucoraja erinacea |
| hake, spotted | Urophycis regia | skate, winter | Leucoraja ocellata |
| herring, Atlantic | Clupea harengus | spot | Leiostomus xanthurus |
| herring, alewife | Alosa pseudoharengus | striped bass | Morone saxatilis |
| herring, blueback | Alosa aestivalis | sturgeon, Atlantic | Acipenser oxyrinchus |
| hogchoker | Trinectes maculatus | tautog | Tautoga onitis |
| jack, crevalle | Caranx hippos | toadfish, oyster | Opsanus tau |
| kingfish, northern | Menticirrhus saxatilis | weakfish | Cynoscion regalis |
| lizardfish, inshore | Synodus foetens |  |  |

Table 5.14. List of invertebrates observed in 2016.
In 2016, thirty-nine invertebrate" species" were identified. In most cases, invertebrates are identified to species; however, species that are very similar are identified to genus, and in difficult cases, to a higher taxon.

| Common Name | Scientific Name | Common Name | Scientific Name |
| :--- | :--- | :--- | :--- |
| Tubularia hydroids | Tubularia, spp. | lobster, American | Homarus americanus |
| anemones | anemomes spp. | mussel, blue | Mytilus edulis |
| arks | Noetia-Anadara spp. | northern moon snail | Lunatia heros |
| bryozoan, bushy | Phylum Bryozoa | oyster, common | Crassostrea virginica |
| clam, common razer | Ensis directus | polychaetes | Class polychfeta |
| clam, hard clams | Artica-Mercinaria-Pitar sp. | sea urchin, purple | Arbacia punctulata |
| clam, surf | Spisula solidissima | shrimp, ghost | Gilvossius setimanus |
| coral, star | Astrangia poculata | shrimp, mantis | Squilla empusa |
| crab, mud | Family Xanthidae | shrimp, sand | Crangon septemspinosa |
| crab, Japanese shore | Hemigrapsus sanguineus | slipper shell, common | Crepidula fornicata |
| crab, blue | Callinectes sapidus | sponge spp. | sponge spp. |
| crab, flat claw hermit | Pagurus pollicaris | sponge, red bearded | Cliona celate |
| crab, horseshoe | Limulus polyphemus | squid, bobtail | Microciona prolifera |
| crab, lady | Ovalipes ocellatus | squid, longfin inshore | Sepioid spp. |
| crab, rock | Cancer irroratus | starfish spp. | Loligo pealeii |
| crab, spider | tunicates, misc | Asteriid spp. |  |
| hydroid spp. | whelk, channeled | misc. class ascidiacea |  |
| jelly, comb | whelk, knobbed | Busycotypus canaliculatus |  |
| jelly, water | hydroid spp. | Busycon carica |  |
| jellyfish, lion's mane | Phylum Ctenophora | Rhacostoma atlanticum | Cyanea capillata |

Names taken from: A Field Guide to the Atlantic Seashore, Peterson Field Guide Series, 1978 (Gosner, 1978).

Table 5.15. Total number and weight (kg) of finfish and invertebrates caught in 2016.
Finfish species are in order of descending count. Invertebrate species are in order of descending weight (nc $=$ not counted). Young-of-year anchovies and Gadids are neither separated by species nor quantified; young-of-year Atlantic herring and American sand lance are not quantified. Number of tows (sample size) $=196$.

| species | count | \% | weight | \% | species | count | \% | weight | \% |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 5.18. Spring indices of abundance for selected species, 1984-2016.
The geometric mean count per tow was calculated for 38 finfish and 2 invertebrates using April-June data. An asterisk next to the species name and time series mean, indicates that the spring index is a better estimate than the fall index (Simpson et al. 1991). Two asterisks indicate that both the spring and the fall indices provide good estimates.

## Table 5.19. Fall indices of abundance for selected species, 1984-2016.

The geometric mean count per tow was calculated for 38 finfish and 2 invertebrates using September-October data. An asterisk next to the species name and a time series mean, indicates that the fall index provides a better estimate than the spring index (Simpson et al. 1991). Two asterisks indicate that both the spring and the fall indices provide good estimates. There was no fall sampling in 2010.

Table 5.20. Finfish and invertebrate biomass indices for the spring sampling period, 1992-2016.
The geometric mean weight (kg) per tow was calculated for 38 finfish and 15 invertebrate species for the spring (April-June) sampling period.

|  | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 5.21. Finfish and invertebrate biomass indices for the fall sampling period, 1992-2016.
The geometric mean weight (kg) per tow was calculated for 38 finfish and 15 invertebrate species for the fall (Sept-Oct) sampling period. There was no fall sampling in 2010.

Table 5.22. Bluefish indices of abundance, 1984-2016.
Using September and October length data, the geometric mean catch per tow was calculated for two age groups of bluefish: age-0 and all fish age 1 and older. Age-0 was defined as bluefish less than 30 cm fork length.

| Year | Fall |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $\begin{gathered} \text { age } 0 \\ \text { count / tow } \end{gathered}$ | $\begin{gathered} \text { age } 0 \\ \text { kg / tow } \\ \hline \end{gathered}$ | $\begin{gathered} \text { ages } 1+ \\ \text { count / tow } \end{gathered}$ | $\begin{aligned} & \text { ages } 1+ \\ & \text { kg / tow } \end{aligned}$ |

Job 5 Page 36

Table 5.23. Scup indices-at-age, 1984-2016.
Spring (May and June) and fall (September and October) catch and age data were used to determine the geometric mean indices-atage ${ }^{I}$. The spring and fall age keys were used to expand length frequencies to age frequencies and then the spring and fall overall indices were proportioned by the percentage of fish in each age. The 0-10+ index represents the overall index (sum of ages 0-10+), and the adult $2+$ index is provided as the sum of ages $2-10+$ index. Fish older than age 9 were included in the age $10+$ index ${ }^{2}$.

| Year | Spring (May-June) |  |  |  |  |  |  |  |  |  |  |  |  |

In 1984, 1985, 2003, 2004, 2006, 2008, 2010, 2011, and 2014 less than the number of scheduled tows were conducted in some months (Table 5.4). Fish in the age 10+ group include: 6 fish taken 1984-1988, 8 fish taken 2002-2010, 81 taken in 2011, 28 taken in 2012, 26 taken in 2013, 15 taken in 2014, 37 fish in 2015 and 29 fish in 2016. The oldest scup aged were two 15-year-old fish taken in 2015.

Table 5.24. Age frequency of striped bass taken in spring, 1984-2016.
Ages were derived from trawl survey length data using the average of Hudson River and Chesapeake Bay von Bertalanffy parameters.

Note: number of fish taken but not measured = one in 1984, one in 1988, two in 1990.

Table 5.25. Striped bass indices-at-age, 1984-2016.
Spring length data was converted to ages using the average of Hudson River and Chesapeake Bay von Bertalanffy parameters (Vic Crecco, pers comm). Indices-at-age were then determined by apportioning the spring indices (from Table 5.18) by the percentage of fish in each age.

| Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 5.26. Summer flounder indices-at-age, 1984-2016.
Year and season specific age keys obtained from the NMFS spring and fall surveys were used to convert LISTS length frequencies to ages. Starting in 2000 LISTS ageing data ( 60 cm and over) were added to the age key to supplement the older age groups. In 2015-2016, LISTS age data for smaller fish were also incorporated into the age key. Indices-at-age were determined for each season by apportioning the spring and fall overall indices (from Table 5.18 and Table 5.19) by the percentage of fish in each age.

note: 1984-1999 indices-at-age were run using a GT 60 cm group in the age key.

Table 5.27. Tautog indices-at-age, 1984-2015.
Year and season specific age keys obtained from the LISTS spring and fall surveys were used to convert LISTS length frequencies to ages. Indices-at-age were then determined for each season by apportioning the spring and fall overall indices (from Table 5.18 and Table 5.19) by the percentage of fish in each age, and then summing the spring and fall indices-at-age. The age 1$20+$ index is the sum of indices ages $1-20+$. The age 20+ category includes 36 fish ranging from 20 to 30 years of age.

|  | Age |  |  |  |  |  |  |  |  |  |  |

Job 5 Page 40

Table 5.28. Weakfish age 0 and age $1+$ indices of abundance, 1984-2016.
Using spring (May, June) and fall (September, October) length data, the geometric mean catch per tow was calculated for three groups of weakfish: fall age-0, spring - all fish age 1 and older (1+), and fall - all fish age 1 and older (1+). Weakfish less than 30 cm fork length in the fall were defined as age-0.

| Year | Fall |  | Fall |  | Spring |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\begin{gathered} \text { age } 0 \\ \text { count } / \text { tow } \end{gathered}$ | $\begin{gathered} \text { age } 0 \\ \text { kg / tow } \\ \hline \end{gathered}$ | $\begin{gathered} \text { ages } 1+ \\ \text { count / tow } \end{gathered}$ | $\begin{gathered} \text { age } 1+ \\ \text { kg / tow } \\ \hline \end{gathered}$ | $\begin{gathered} \text { ages } 1+ \\ \text { count / tow } \end{gathered}$ | $\begin{aligned} & \text { ages } 1+ \\ & \text { kg / tow } \\ & \hline \end{aligned}$ |

Table 5.29. Winter flounder indices-at-age, 1984-2016.
The Long Island Sound Trawl Survey April and May catch and age data was used to calculate the geometric mean indices-at-age. An April-May age key was used to convert lengths to ages, and an overall April-May index (the ages 1-13 index in the table) was apportioned by the percentage of fish at age. The $4+$ index is the sum of indices ages 4-13 and represents the abundance of winter flounder that are recruited to the fishery. The age-0 indices were obtained from the Estuarine Seine Survey (Job 8). Indices-at-age for 2016 are based on a 2014/2015 pooled key.

Note years with non-standard \# of tows: 1984: April = 0 tows, May $=13$ tows, and 19 tows in June used to increase sample size; 1985: April = 0 tows, May = 41 tows; 1992 and 2006: April $=0$ tows, May $=40 ; 1996$ : April $=17$ tows, May $=63$ tows; 2005: April $=35$ tows, May $=45$ tows; 2007 : April $=35$ tows, May $=$ 45 tows; 2008: April = 36, and May = 44 tows; 2010: May = 38 tows; 2011: April = 12 tows; 2016: April = 36 tows .

TABLES 5.30-5.66 LENGTH FREQUENCIES LISTS

Table 5.30. Alewife length frequencies, spring and fall, 1 cm intervals, 1989-2016.
From 1989-1990, lengths were recorded from the first three tows of each day; since 1991, lengths have been recorded from every tow.

| length | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 5.31. American shad length frequencies, spring and fall, 2.0 cm intervals (midpoint given), 1989-2016.
From 1989-1990, lengths were recorded from the first three tows of each day; since 1991, lengths have been recorded from every tow.

| length | 1989 | 1990 | 1991 | 1992 | 1993 | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | $\begin{gathered} \text { Spring } \\ 2002 \\ \hline \end{gathered}$ | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 | 2015 | 2016 |

Table 5.33. American lobster length frequencies-fall, female, 1 mm intervals, 1984-2016.
Lobsters were measured from each tow.

| Female | Fall |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 5.35. American lobster length frequencies-fall, male, 1 mm intervals, 1984-2016.
Lobsters were measured from each tow.

| Male | Fall |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 5.36. Atlantic herring length frequencies, spring and fall, $1 \mathbf{c m}$ intervals, 1989-2016.
From 1989-2013, Atlantic herring lengths were recorded from the first three tows of each day; since 2014, lengths have been recorded from every tow.

Table 5.37. Atlantic menhaden length frequency, spring and fall, $1 \mathbf{c m}$ intervals, 1996-2016.
Menhaden are scheduled to be measured from every tow. However, the following numbers of menhaden were not measured: 5 juveniles and 4 adults in 1996, and 7 adults in 1997.

Table 5.38. Black sea bass length frequencies, spring, 1 cm intervals, 1986-2016.
Since 1987, black sea bass have been measured from every tow.

Table 5.40. Blueback herring length frequencies, spring and fall, 1 cm intervals, 1989-2016.
From 1989-1990, lengths were recorded from the first three tows of each day; since 1991, lengths have been recorded from every tow.

| length | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Job 5 Page 56

Table 5.43. Butterfish length frequencies, 1 cm intervals, spring and fall, 1986-1990, 1992-2016.
Prior to 2014, length frequencies of butterfish were taken from the first three tows of each day; since 2014, lengths have been recorded from every tow.

| length | Spring |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Table 5.46. Fourspot flounder length frequencies, spring and fall, 2 cm intervals (midpoint given), 1989, 1990, 1996-2016.
Prior to 2014, Fourspot flounder lengths were recorded from the first three tows of each day; since 2014, lengths have been recorded from every tow.

Table 5.51. Long-finned squid length frequencies, fall, 1 cm intervals, 1986-1990, 1992-2016.
From 1986-1990, and 1992-2013, Length frequencies of squid taken from the first three tows of each day; since 2014, lengths have been recorded from every tow.

| length | 1986 | 1987 | 1988 | 1989 | 1990 | 1992 | 1993 | 1994 | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | $\begin{array}{r} \text { Fal } \\ 20001 \end{array}$ | 2002 | 2003 | 2004 | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 | 2015 | 2016 |

Table 5.54. Striped bass spring length frequencies, $\mathbf{2} \mathrm{cm}$ intervals (midpoint given), 1984-2016.
All striped bass taken in the Survey were measured, with the exception of one fish taken in 1984, one in 1988, and two in 1990.

Table 5.55. Striped bass fall length frequencies, $\mathbf{2} \mathbf{~ c m ~ i n t e r v a l s ~ ( m i d p o i n t ~ g i v e n ) , ~ 1 9 8 4 - 2 0 1 6 . ~}$
All striped bass taken in the Survey were measured on each tow.

Table 5.61. Weakfish length frequencies, fall, 2 cm intervals (midpoint given), 1984-2016.
Weakfish were measured from every tow, with the exceptions of 968 juveniles in 1988 and 863 juveniles in 1989 that were not measured.

Table 5.62. Windowpane flounder length frequencies, spring, 1 cm intervals, $1989,1990,1994-2016$.
Prior to 2014, lengths were recorded from the first three tows of each day; since 2014, lengths have been recorded from every tow.

Table 5.63. Windowpane flounder length frequencies, fall, 1 cm intervals, 1989, 1990, 1994-2016.
Prior to 2014, lengths were recorded from the first three tows of each day; since 2014, lengths have been recorded from every tow.

| length | Fall |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

Winter skate were scheduled to be measured from every tow. However, the following numbers of skate were not measured: 4 in 1995, 10 in 1996, and 2 in 1997.

FIGURES 5.1-5.18 LISTS

Figure 5.1. Trawl Survey site grid. Each sampling site is $1 x 2$ nmi (nautical miles). A four-digit number identifies the site: the first two digits are the row numbers (corresponding to minutes of latitude) and the last two digits are the column numbers (corresponding to two nautical miles in length on the longitudinal axis). Examples: site 1428 near Guilford and 0028 near Mattituck. (Note: The sites in column 16 are approximately $2 x 1$ nmi. The grid was drawn on the Eastern and Western Long Island Sound 80,000:1 nautical charts, which overlap by the area in column 16.)

Figure 5.2. April 2016 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Samples collected from a different site than published in the "Notice to Fishermen" are noted in table below map.

| Month | Sample | Site Sampled | Sampled Strata | Site Selected | Selected Strata | Reason Not Sampled |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| April |  |  |  | 0324 | M4 | logistical issues and time constraints |
| April |  |  |  | 0327 | T3 | logistical issues and time constraints |
| April |  |  |  | 0428 | S3 | logistical issues and time constraints |
| April |  |  |  | 0721 | M3 | logistical issues and time constraints |

Job 5 Page 83

Figure 5.3. May 2016 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Samples collected from a different site than published in the "Notice to Fishermen" are noted in table below map.

| Month | Sample | Site <br> Sampled | Sampled <br> Strata | Site <br> Selected | Selected <br> Strata |
| :--- | :--- | :--- | :--- | :--- | :--- |
| May |  |  |  |  | No sites were moved during this cruise |

Job 5 Page 84

Figure 5.4. June 2016 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Samples collected from a different site than published in the "Notice to Fishermen" are noted in table below map.

|  |  | Site | Sampled | Site | Selected |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Month | Sample | Sampled | Sason Moved <br> Strata | Selected | Strata | Reason |
| June |  |  |  |  | No sites were moved during this cruise |  |

Figure 5.5. September 2016 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Samples collected from a different site than published in the "Notice to Fishermen" are noted in table below map.

| Month | Sample | Site <br> Sampled | Sampled <br> Strata | Site <br> Selected | Selected <br> Strata | Reason Moved |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| September | FA2016001 | 1837 | T1 | 1737 | T1 | obstruction along planned towpath |

Job 5 Page 86

Figure 5.6. October 2016 sites selected and sampled. The red outlined rectangles are the sites selected for the cruise and the blue dots are the sites sampled. Samples collected from a different site than published in the "Notice to Fishermen" are noted in table below map.

|  |  | Site | Sampled | Site | Selected |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Month | Sample | Sampled | Strata <br> Selected | Strata | Reason Moved |
| October |  |  |  |  | No sites were moved during this cruise |

Job 5 Page 87

Figure 5.7. Number of finfish species observed annually, 1984-2016. Note: there was no October sampling in 2006 and there was no June, September or October sampling in 2010. Average number of finfish species caught per year is 57.8 for the time-series. See Table 5.4 for details on number of tows completed each year.

Figure 5.8. Plots of abundance indices for: black sea bass, bluefish (total, age 0, and ages $1+$ ), butterfish, cunner, and dogfish (smooth and spiny).

Legend:

$$
\begin{aligned}
\square & =\text { count } / \text { tow } \\
\boldsymbol{\Delta} & =\mathrm{kg} / \text { tow } \\
---- & =\text { mean count } / \text { tow }
\end{aligned}
$$

$$

Figure 5.15. Mean number of finfish species per sample, spring and fall, 1984-2016. This index measures the diversity of species supported within the Sound's various habitats.

Figure 5.16. Open water forage abundance, 1992-2016. The geometric mean is calculated as the aggregate sample biomass per tow of 14 of the most common forage species sampled in the survey. This index measures the available food base which supports both resident and migratory species. The average since 1992 is $14.56 \mathrm{~kg} / \mathrm{tow}$ (red line).

## Open Water Forage Abundance

Geometric Mean Weight per Tow(kg) for 14 Common Forage Species

Figure 5.17. Geometric mean biomass of finfish and invertebrates per sample, spring and fall, 1992-2016. This index measures the diversity of species supported within the Sound's various habitats.

Geometric Mean Weight of Finfish and
Invertebrates per Tow, Fall 1992-2016

Figure 5.18. Trends in the number of cold temperate versus warm temperate species per sample captured in spring and fall LIS Trawl Surveys. See Appendix 2.5 for list of species included in analysis.

Mean Number of Species per Sample in Fall for Cold-temperate and Warm-temperate Groups

## APPENDICES

LISTS

Appendix 5.1. List of finfish species identified by A Study of Marine Recreational Fisheries in Connecticut (F54R) and other CT DEEP Marine Fisheries programs. LISTS has collected one hundred-eleven (111) finfish species from 1984-2016.
This appendix contains a list of 154 species identified (Bold type indicates new species) from all sampling programs conducted since 1984. Species are listed alphabetically by common name (Nelson et al. 2004). Sampling program abbreviations, survey time periods and gear type are as follows:

| Survey Abbreviation | Survey Description | Time Period | Gear Type |
| :---: | :---: | :---: | :---: |
| CTR | CT River Creel Survey | 1997-1998 | bus stop creel survey mainstem of CT River |
| EPA | cooperative sampling in western LIS with EPA | 1986-1990 | used LISTS net |
| ESS (F54R) | Estuarine Seine Survey | 1988 to present | $7.6 \mathrm{~m}(25 \mathrm{ft})$ beach seine |
| IS (F54R) | Inshore Survey of Juvenile Winter Flounder | 1990-1994 | beam trawls (also a little data from 1995-1996) |
| ISS (F54R-starting 2008) | Inshore Seine Surveys in CT \& TH rivers | 1979 to present | $15.2 \mathrm{~m}(50 \mathrm{ft})$ bag seine set by boat |
| LISTS (F54R) | Long Island Sound Trawl Survey | 1984 to present | 14 m ( 50 ft ) trawls with 2 " codend mesh |
| MC (F54R) | Marine Creel Surveys | 1985 to present | Marine Angler Surveys |
| MISC | misc sampling conducted on R/V Dempsey | various | various |
| NCA | "inshore" EPA NCA C2K sampling | 2000 | skiff trawls |
| NRRWS | sampling in western end of LIS, the "Narrows" | 2000-2007 | $14 \mathrm{~m}(50 \mathrm{ft})$ trawls with 2 " codend mesh |
| SNFH (F54R) | Study of Nearshore Finfish Habitat | 1995-1996 | plankton net |
| SS (F54R) | Summer Survey | 1991-1993, 1996 | $14 \mathrm{~m}(50 \mathrm{ft})$ trawls with codend liner in LIS |
| TN | Trap Net Survey | 1997-1998 | trap nets in rivers |

## Finfish not ranked

anchovy spp, yoy
Atlantic herring, yoy
American sand lance (yoy)

Appendix 5.4. cont. Total number and weight (kg) of finfish and invertebrates caught in 2011.
Finfish species are in order of descending count. Invertebrate species are in order of descending weight (nc $=$ not counted). Young-of-year bay and striped anchovy are neither separated by species or quantified; young-of-year Atlantic herring and American sand lance are not quantified. Number of tows (sample size)=172.

Appendix 5.5: Endangered Species Interactions: Twelve (12) Atlantic sturgeon were captured on eight (8) of the 196 tows completed in 2016; a higher encounter rate (4.1\%) than average for the LISTS time series of tows ( $2.3 \%$ ). The Atlantic sturgeon captures occurred over all survey bottom types (sand, mud and transition), and in all but the shallowest $(<9 \mathrm{~m})$ depth interval. All individuals were released alive and uninjured, and were reported to NMFS within 24 hours. Details for each individual are provided below:

Appendix 5.6: Cold and warm temperate species captured in LISTS. Thirty-three (33) species are included in the cold temperate group, while thirty-four (34) species are included in the warm temperate group. Cold temperate species are defined as being more abundant north of Cape Cod, MA than south of New York, behaviorally adapted to cold temperatures including subfreezing but prefers $\sim 3-15^{\circ} \mathrm{C}$, and spawns at lower end of temperature tolerance. Warm temperate species are defined as being more abundant south of New York than north of Cape Cod, MA, behaviorally avoids temperatures $<7-10^{\circ} \mathrm{C}$; prefers $\sim 11-22^{\circ} \mathrm{C}$, and spawns at higher end of temperature tolerance.

## JOB 6: STUDIES IN CONSERVATION ENGINEERING

## GOAL

Evaluate new technologies and methodologies for potential inclusion in the Long Island Sound Trawl Survey or other Surveys of this Project.

## OBJECTIVES

1) Characterize catch composition and selectivity patterns using different gear combinations for Connecticut's marine fishery-independent monitoring surveys. Particular emphasis will be placed on evaluating modern trawl net design/materials and door combinations for potential use on the Long Island Sound Trawl Survey.
2) Evaluate impacts of gear changes on associated thirty-year time series data which are used in numerous coastal stock assessments, management decisions, essential fish habitat analysis and climate change studies.
3) Assess electronic data acquisition systems for fisheries research for potential benefits of modernizing the Long Island Sound Trawl Survey or other Surveys of this Project.
4) Assess new software applications to integrate the components of an onboard electronic data acquisition system with a computerized database for data collection and QA/QC for the Long Island Sound Trawl Survey or other Surveys of this Project.

## INTRODUCTION

Work during this segment focused on Objectives 3 and 4, however future segments may focus on other Objectives.

Long Island Sound Trawl Survey (LISTS) staff are attempting to upgrade the data collection processes that have been in place since the inception of the survey 33 years ago. Although paper and pencil for recording data on research vessels has worked well for LISTS for decades, a number of similar fish surveys along the coast have been using electronic data acquisition hardware and software successfully for quite some time. Some surveys, notably the Northeast Federal bottom trawl surveys, have been mostly digital for over a decade now. Recent improvements in software and hardware are making a digital onboard system more realistic for the LISTS. Project staff canvassed staff from other surveys and investigated the components that would be required to configure a mostly wireless data collection system for the 50 ' R/V John Dempsey that would likely include an onboard computer network of electronic scales, measuring boards and mobile devices. Although electronic fisheries data acquisition systems can be expensive, they typically improve the accuracy and efficiency of fisheries independent surveys by streamlining sampling procedures and decreasing transcription errors at sea, as well as decreasing or eliminating data entry and key punch errors and QA/QC procedures in the office. All of these improvements result in better quality data being available more quickly for fisheries management decisions.

## METHODS

Two main aspects of LISTS make it difficult for LISTS to mimic the setup on the other Surveys. The first issue is the smaller vessel with much less deck space available to LISTS compared to other surveys. Other surveys have enough deck space to accommodate metal tables with windshields affixed to the deck while still having deck space to spill the codend and sort the catch. For LISTS, the sorting table becomes the measuring table once sorting is completed, so measuring workstations cannot be left set up on deck in between tows. Thus, any components for measuring stations need to be easily set up and taken down multiple times each day.

The second main issue for LISTS is that all of the gear has to be removed from the research vessel so gear for the Long Island Sound Ambient Water Quality Monitoring Program (Job 10) can be loaded. This means that, even if measuring stations could be affixed to the deck for the trawl survey, they would need to be removed for the water survey. This unloading/loading of gear occurs at least ten times each year and frequently there is only a few hours available to complete the transition.

The other large-scale trawl surveys that were canvassed about their electronic data acquisition systems were primarily set up with hardwired components on semi-permanent workstations. LISTS' need to be able to easily and quickly set up and remove components for electronic measuring stations means components need to be wireless and/or Bluetooth capable as much as possible.

Schematic of how the components of an electronic data acquisition system might be situated on the R/V John Dempsey.

## RESULTS

After evaluating numerous options for the components of an electronic data acquisition system for fisheries research under the previous segment, efforts during this project segment focused on procuring components for the new LISTS system. Principle components purchased during this segment include: Xplore Technologies Tablets, Bigfin measuring boards, Marel weighing scales, waterproof keyboards, YSI EXO water quality Data Sonde, Zebra GK420t label printers, and license for FEED software.

There is still a significant amount of work to be done before there is a functioning system. Components that still need to be acquired include laptop for server, wireless router for networking, NAS for backup of data and UPS for uninterrupted power supply. Custom mounting brackets for tablets, keyboards and electronic measuring boards need to designed and fabricated, as well.

A customized software application is being designed to coordinate all of the electronic components and incorporate standardized LISTS protocols for data collected from each sample, data storage and quality assurance. Information on current LISTS protocols for sampling, sub-sampling, recording data at sea, data entry, and database management (including data dictionary and error checking procedures) have been shared with the contractor who is developing a custom FEED application for LISTS.

## MODIFICATIONS

None: due to the nature of evaluating new technologies, it is not known ahead of time which ideas will be implemented. Therefore, the specific Objectives of this Job are likely to change over time. However, in the next segment of the Project, we expect to conduct beta testing of the components of an electronic data acquisition system purchased for the LISTS. We also expect to continue development of the FEED software being customized for the LISTS.

JOB 7: ALOSINE SURVEY

## JOB 7: AMERICAN SHAD MONITORING AND INSHORE SEINE SURVEYS

GOAL
To monitor relative abundance and distribution of American shad and other fish in Connecticut's nearshore waters.

## OBJECTIVES

Provide:

1) Information on the adult American shad spawning population: commercial catch, age structure, sex ratio and size.
2) Annual indices of relative abundance for juvenile shad, blueback herring and common nearshore marine species.

## STUDY PERIOD AND AREA

This report contains information on adult American shad monitoring and seine studies on juvenile American shad (Alosa sapidissima), blueback herring (Alosa aestivalis), menhaden (Brevoortia tyrannus) and common nearshore marine species. Areas of the Connecticut River sampled range from Holyoke, MA to Essex, CT. The Thames River seine survey begins just south of Norwich Harbor and ends in Uncasville, CT. Time series data collected under a previous funding source are also included.

This project was funded by USFWS through a State Wildlife Grant (F14AF01185; T-14-R-1) awarded from September 1, 2014 date through December 31, 2016 and was reinstated on F54 on January 1, 2017. For the sake of consistency and formatting, the activities and accomplishments for monitoring during that period have been included here in their entirety.

To continue to provide long-term monitoring of alosine abundance and population structure in Connecticut. To document occurrence of forage fish in Connecticut's nearshore waters.

## Project Objectives

- Characterize the adult American shad (Alosa sapidissima) spawning population in the Connecticut River: sex ratio, size structure, age structure, and spawning history.
- Calculate annual indices of relative juvenile abundance for American shad and blueback herring ( $A$. aestivalis), and document occurrence of other estuarine and marine species.

## Study Period and Area

This report contains information on monitoring of adult and juvenile American shad, juvenile blueback herring, and other estuarine and marine fishes during the study period of September 1, 2014-August 30, 2016. Areas of the Connecticut River sampled ranged from Holyoke, MA to Essex, CT. Areas of the Thames River sampled ranged from Norwich, CT to Uncasville, CT. This report includes data collected under previous funding sources.

## Introduction and Background

The American shad (hereafter just referred to as "shad"), the largest member of the herring family, is an anadromous fish that undertakes spring spawning migrations into a number of Atlantic coastal rivers including the Connecticut River. Annual shad spawning migrations in the Connecticut River have supported both recreational and commercial fisheries in Connecticut, as well as recreational fisheries in upriver states, for generations. Shad have been an important food fish in the Connecticut River since colonial days and once supported one of the most economically valuable fisheries in Connecticut. Because of its historical importance to Connecticut, the American shad was designated the State Fish in 2003. The Connecticut River remains one of the most productive shad rivers in New England.

The State of Connecticut Department of Energy and Environmental Protection Fisheries Division (CT DEEP) has conducted surveys on shad since 1974. The Connecticut River shad population is one of the most well studied on the Atlantic coast, and has been the subject of a long-running CT DEEP research study that has compiled one of the only available continuous long-term time series of shad abundance and demography data. CT DEEP provides data on Connecticut River shad to a variety of groups including the US Fish and Wildlife Service, NOAA National Marine Fisheries Service (NMFS), the Atlantic States Marine Fisheries Commission (ASMFC), and various academic and research institutions. For decades, Connecticut's shad studies were funded by NMFS through the Anadromous Fish Conservation Act of 1965. This source of funding was eliminated in 2009 and has not since been reinstated. Due to declines in annual budgets and staffing levels, some CT DEEP shad monitoring activities have been discontinued or now only occur on an opportunistic basis. The annual shad monitoring that CT DEEP currently maintains for the Connecticut River includes assessments of harvest in the commercial fishery, adult abundance,
and adult population characteristics such as sex ratio, size and age structure, and spawning history (i.e. frequency of repeat-spawning). Monitoring of abundance and population structure is accomplished in cooperation with the Massachusetts Division of Fish and Wildlife (MA DFW), which monitors fish passage at the Holyoke Dam (first mainstem dam on the river) in Holyoke, MA (Slater 2016). In addition, CT DEEP conducts an annual summer-fall seine survey targeting juvenile shad that documents year class strength and thus predicts potential recruitment of adult shad to the Connecticut River run in future years.

Blueback herring, another anadromous herring native to the Atlantic coast, have experienced substantial population declines range-wide. Prior to 1986, approximately 500,000 adult blueback herring were passed annually at the Holyoke Dam fish lift, but annual passage declined steadily after 1995 and has remained below 1,000 since 2003. The decline of blueback herring in the Connecticut River along with a decline of closely-related alewife (A. pseudoharengus) in some Connecticut coastal streams led to the 2002 declaration of a moratorium on "river herring" (collective term for blueback herring and alewife) harvest in Connecticut. River herring were subsequently listed as Species of Special Concern by NMFS to bring awareness to data deficiencies and associated uncertainties around population status. In 2005, Connecticut's Endangered Species Scientific Taxonomic Advisory Committee for Fish listed blueback herring as a State Species of Special Concern.

CT DEEP has monitored juvenile blueback herring abundance in the Connecticut River since 1978 as part of the previously-discussed annual seine survey. Despite declines in adult abundance at the Holyoke lift, the annual blueback herring juvenile index has continued to indicate reproductive success in the river stretch south of Holyoke in most years. The CT DEEP seine survey is the only source of continuous long-term data on juvenile blueback herring in the Connecticut River.

Juvenile alosine (a term referring to fish of the genus Alosa) sampling was expanded to the Thames River system after 1996 to monitor the impacts of a newly installed fish lift at the Greenville Dam. CT DEEP initiated the Thames River seine survey to estimate juvenile production of shad and blueback herring. Sites were chosen based on previous work conducted by CT DEEP in that river system. Since 1996, the survey has collected few juvenile alosines, but has documented catches of forage fish, many of which are listed as species of greatest conservation need (GCN) in Connecticut's 2015 Wildlife Action Plan (CT DEEP 2015). This survey therefore addresses several high priority actions outlined in the Connecticut Wildlife Action Plan including: continuation of long term monitoring, compiling baseline information on GCN species, monitoring population fluctuations, and assessing distribution and abundance by life stage. In particular, this survey has provided information on several GCN species, including:

- GCN Most Important: alewife, Atlantic tomcod, blueback herring, tautog and winter flounder
- GCN Very Important: American shad, cunner, fourspine stickleback.
- GCN Important: Atlantic menhaden, Atlantic silverside, bay anchovy, golden shiner, hogchoker, largemouth bass, northern pipefish, white sucker and yellow perch.

## METHODS

## Adult American Shad

The adult shad population was characterized by information collected annually at the Holyoke Fish lift. Daily fish lift numbers, daily sex ratio, and number of days of lift operation were reported by MASS DFW. The annual sex ratio was calculated by weighting the daily sex ratios by the number of fish lifted daily. MASS DFW staff also collected scale samples from a daily subsample of adult shad and provided these samples to CT DEEP. Scales were used to characterize age structure and spawning history. All shad sampled for scales were measured to fork length (mm), and approximately 25 scales were removed from above the lateral line anterior to the dorsal fin of each fish. Sex determination was accomplished by external inspection for sex-specific characters and expression of gametes. Some shad were sacrificed to verify sex determination.

Scale samples were stratified by sex and $1-\mathrm{cm}$ length group, and a representative number of samples was chosen from each stratum for analysis. CT DEEP staff processed scale samples by first immersing them in a soap solution and then cleaning them with an ultrasonic cleaner. Three to five representative scales were selected from each sample and then pressed onto acetate using an Ann Arbor roller press. Age determinations were made as the consensus of two or more readers viewing projected images ( 43 x ) and counting annuli and spawning scars (indicative of previous spawning events) according to the criteria of Cating (1953). Ages and repeat spawning frequencies were extrapolated to the annual lift count by direct proportion.

## Connecticut River Seine Survey

Collections of juvenile shad and juvenile blueback herring were made weekly from mid-July through mid-October at seven fixed locations ranging from Holyoke MA to Essex CT. Seine haul locations and techniques were identical to those used by CT DEEP in the Connecticut River seine survey since 1978. The sampling sites for this survey were chosen based on location, physical conditions and accessibility (Marcy 2004, Crecco et. al. 1981, Savoy and Shake 1993). One seine haul per station was made during daylight hours with a 15.2 m nylon bag seine ( 0.5 cm delta mesh) and 30.5 m lead ropes. The seine was fished with the aid of a boat to deploy it upstream and offshore. Using the lead ropes, the seine was towed in a downstream arc to the shore and beached. Species in the family Clupeidae (shad, blueback herring, alewife, and Atlantic menhaden Brevoortia tyrannus) were returned to the laboratory for measurement and identification. All fish species other than those from the family Clupeidae were identified, quantified, and released. To facilitate returning large catches of fish quickly to the water and thus minimizing mortality, some fish were identified only to the family or genus level (e.g. sunfish, catfish, killifish). Large catches of common species were estimated with a visual count to minimize handling and processing time. In the laboratory, juvenile clupeids were identified to species by the criteria of Lippson and Moran (1974) and counted. For each sample, up to 40 randomly selected clupeids of each species were measured to total length (mm).

The juvenile abundance index ( $J I$ ) for shad and blueback herring in each year was calculated as a geometric mean catch per seine tow (Gottschall and Pacileo 2016):

$$
J I=e^{\left(\left(\sum_{a} \ln \left(n_{a}+1\right)\right) / T\right)-1}
$$

where: $n_{a}=$ number of shad or herring collected in seine tow $a$, and $T=$ total number of seine tows conducted in that year among all sites and sample dates. The geometric mean is the preferred method when reporting to ASMFC because it normalizes clustered data.

## Thames River Seine Survey

Up to seven fixed stations were sampled twice monthly during the same time frame as the Connecticut River seine survey. Gear and methods used in the Thames River survey were identical to those used in the Connecticut River survey.

## RESULTS

## Adult Shad Monitoring at Holyoke

All results collected during the funding timeframe of September 1, 2014 through August 31, 2016 are presented below. To compare the 2014-2016 juvenile abundance indices to all values of the time series, data collected prior to the start of the funding period are also presented.

In 2014, The Holyoke fish lift was open for fish passage during the time period of April 24 through July 15 (lift was closed for a total of 12 days during this period due to high water events or other operational factors). A total of 513 American shad was sampled for scales over 29 different days. The number of shad passed at Holyoke in 2014 was 370,506 , which was above the long-term (1975-2016) mean of 306,046 and ranked as the 13th highest value in the time series.

In 2015, upstream fish passage operations at Holyoke were conducted from April 27 through June 21. Lift operations were discontinued earlier than usual in the season to allow for construction of new downstream passage facilities. The number of shad passed at Holyoke in $2015(412,656)$ was the seventh highest since 1975 and was the second highest since peak passage in 1992 (Figure 1). American shad scales $(\mathrm{n}=816)$ were collected on 40 different days throughout the season.

In 2016, upstream fish passage operations at Holyoke were conducted April 1 through July 15. The number of shad passed at Holyoke in $2016(385,930)$ was the ninth highest since 1975 and the fourth highest since peak passage in 1992 (Figure 1). American shad scales ( $\mathrm{n}=829$ ) were collected on 53 different days. Annual American Shad passage was above the long-term (1975-2016) mean.

## Adult Shad Age Structure

In 2014, 496 ( 187 female, 309 male) scale samples were examined for age and incidence of repeat spawning. The sex ratio at Holyoke was $66 \%$ male and $34 \%$ female. Length of American shad collected at the Holyoke lift ranged from 32.0 to 49.0 cm FL for males and 37.0 to 53.5 cm FL for females (Figure 2). Average size among males and females was 40.6 cm FL and 46.4 cm FL, respectively. Analysis of age structure indicated that adult male shad were from the 2007-2011 year classes. Fifty-seven percent of males were four years old; thirty-four and five percent of males were five and three years old, respectively. Six-year old males comprised 2.5 percent of the sample. Seven-year old males were rare, comprising only 0.3 percent of the sample (Table 1). The majority of female shad sampled ( $59.9 \%$ ) were age five from the 2009 year class. Twenty-one and thirteen percent of females were six and four years old, respectively. As observed for males, seven-year old females were rare (just over $5 \%$ of the sample; see Table 1). The overall incidence of repeat
spawning among both sexes was $3.2 \%$. The repeat spawning frequency was $2.9 \%$ among males and $3.7 \%$ among females (Table 1).

In 2015, scale samples from 229 females and 222 males were examined. The 2015 sex ratio at Holyoke was $57 \%$ male and $43 \%$ female. Length of American shad collected at the Holyoke lift ranged from 30.0 to 47.4 cm FL for males and 34.0 to 51.2 cm FL for females. Average size among males and females was 41.2 cm FL and 45.6 cm FL, respectively. Adult male shad in 2015 were from the 2008-2012 year classes. Twenty-one percent of males were four years old. Sixty-two and two percent of males were five and three years old, respectively. Six-year old males comprised nine percent of the sample (Table 2). The majority of female shad in 2015 ( $65 \%$ ) were age five from the 2010 year class. Twenty-one percent of females were six years old. Thirteen percent of females were four years old; seven-year old females were rare ( $1 \%$ of the sample). The overall incidence of repeat spawning among both sexes in 2015 was $2.0 \%$. The repeat spawning frequency was $1.8 \%$ and $2.2 \%$ among males and females, respectively. (Table 2).

In 2016, scale samples from 294 females and 369 males were processed. Some of these processed samples (received late in the 2016 season) have not yet been aged. The sex ratio at Holyoke was $55 \%$ male and $45 \%$ female. Length of American shad collected at the Holyoke lift ranged from 32.5 to 48.5 cm FL for males and 36.5 to 51.0 cm FL for females. Average size among males and females was 40.0 cm FL and 45.6 cm FL, respectively. Based on scale samples that have been analyzed to-date, adult male shad in 2016 were from the 2009-2013 year classes. Twenty-eight percent of males were four years old. Fifty-one and ten percent of males were five and three years old, respectively. Ten percent of males were six years old; seven-year old males were rare ( $<1 \%$; see Table 3). The majority of female shad in 2016 (47\%) were age five from the 2011 year class. Thirty-eight percent of females were six years old. Twelve and three percent of females were four and seven years old, respectively. The overall incidence of repeat spawning among both sexes in 2016 was $8.4 \%$. The repeat spawning frequency was $5.8 \%$ for males and $11.3 \%$ for females (Table 3). The 2016 repeat spawning frequencies were the highest among the three years in the project period.

## Connecticut River Seine Survey

## American Shad and Blueback Herring Juvenile Abundance Indices

The 2014 seine survey in the Connecticut River was conducted from July 16 through October 15. A total of 3,358 juvenile American shad was collected (Table 4). The highest catch in a single sample in 2014 was 604 shad collected at the Wilson site (RKM 89) in early September, representing $49 \%$ of the total Wilson catch for the season and $18 \%$ of the overall catch among sites (Table 4). The stations that accounted for the largest proportions of the season's catch were Holyoke ( $43 \%$ ) and Wilson ( $36 \%$; see Figure 3). A total of 4,903 blueback herring was collected in 2014 (Table 7).

The juvenile abundance index for shad in 2014 was more than double the 2013 index and ranks as the ninth largest in the time series (Table 10). The 2014 shad index was slightly more than double the blueback herring index.

The 2015 seine survey in the Connecticut River was conducted from July 15 through October 14. A total of 3,448 juvenile American shad was collected (Table 5), which was similar to 2014. The highest catch in a single sample in 2015 was 354 shad collected at the Wilson site (RKM 89) in early September, representing $35 \%$ of the Wilson catch for the season and $29 \%$ of the overall catch among sites (Table 5). The sites that accounted for the largest proportions of the season's catch were Holyoke ( $20 \%$ ) and Wilson ( $29 \%$; see Figure 4). A total of 11,044 blueback herring was collected in 2015 (Table 8), which indicated a moderately large year class (ranked 17th in the time series). The shad abundance index in 2015 (8.53) was comparable to the 2014 index (8.09), and ranks as the eighth largest value in the time series (Table 10, Figure 2).

The 2016 Connecticut River seine survey began on July 13 and continued through October 12. A total of 26,615 juvenile American shad was collected, which was the highest total catch in the entire time series (Table 6). The highest single sample catch in 2016 was 3,744 shad at the Holyoke site in late August. Northern stations accounted for $92 \%$ of the total shad catch (Figure 5). A total of 2,793 blueback herring was collected in 2016 (Table 9). The shad index in 2016 was the highest value in the time series, almost double the 2015 value. The 2016 blueback herring index was the lowest in the time series (Table 10).

Connecticut River shad produced strong year classes in all three years of the project period, including the highest value in the 42 -year time series. Blueback herring produced a weak 2014 year class, a moderate 2015 year class, and a very weak 2016 year class (lowest index value ever recorded). Overall, during the three years of the project period, shad were predominately caught at northern sites while blueback herring were mostly caught at southern sites.

## Species Frequencies of Occurrence

In the 90 hauls completed in 2014, over 37,000 fish were collected, representing 30 species or taxonomic groups. The most abundant species collected were Atlantic menhaden, shiners, blueback herring and American shad. Shiners, juvenile shad, yellow perch, sunfish and blueback herring had the five highest frequencies of occurrence (Table 11).

The 2015 total annual catch was over 87,000 fish and was also comprised of 30 species or taxonomic groups. The large increase in total catch can be attributed to young-of-the-year Atlantic menhaden catch ( 54,621 ), which was $63 \%$ of the total catch and nearly three times higher than the 2014 Atlantic menhaden catch. Blueback herring, shiners and American shad were also in the top five catches (Table 11).

The 2016 total catch was over 64,000 fish. The total catch of Atlantic menhaden $(7,359)$ was the lowest among the three years of the project period. In 2016, American shad and shiners had the highest frequency of occurrence among the project period (Table 11).

## Thames River Seine Survey

The Thames River was sampled on a bi-weekly basis during each of the three project years. The total number of sites sampled annually varied (2014: 27 sites; 2015: 41; 2016: 49). The number of species or taxonomic groups collected in the Thames were comparable among years and ranged from 23 to 28 (Table 12). Atlantic menhaden, Atlantic silverside, killifish, and bluefish were in
the top five occurrences for all three sampling years (Table 12). Atlantic silverside had the highest frequency of occurrence in all three years of the project period. Winter flounder, tautog, and scup were collected in each year. Longhorn sculpin were collected for the first time in this survey in 2014.

Annual Atlantic menhaden catches have varied widely during the 19 years of the Thames survey, from a low in 2013 of just 31 fish, to over a million fish collected in 2000. The 2014 menhaden index (22.78), was the third highest in the overall time series. The 2015 index (14.45) ranked fifth in the overall times series. The 2016 index (5.02) ranked tenth in the time series and was well below the time series mean of 14.9 .

## JOB 8: ESTUARINE SEINE SURVEY

GOAL
To monitor the abundance and size composition of near-shore young-of-year and forage fish resources, with physical habitat parameters, in order to evaluate the effects of fishing and environmental conditions on the distribution and abundance of marine resources in Long Island Sound.

## OBJECTIVES

1) Provide an annual index of recruitment for winter flounder (Age0, 1+), all finfsh species taken, and all crab species.
2) Provide an annual total count for all finfish taken.
3) Provide an index for shallow subtidal forage species abundance.

## METHODS

Eight sites (Figure 8.1) are sampled during September using an eight-meter ( 25 ft .) bag seine with 6.4 mm ( 0.25 in .) bar mesh. Area swept is standardized to 4.6 m ( 15 ft. ), width by means of a taut spreader rope and a 30 m ( 98 ft .), measured distance, parallel to, or at a $45^{\circ}$ angle to the shoreline, against the current or tide if present. At each site, six seine hauls are taken within two hours before and after low slack tide during daylight hours. All sites have been sampled since 1988 except Milford which was added in 1990.

Finfish, crabs, and other invertebrates taken in each sample are identified to species or lowest practical taxon (full listing given in Appendix 8.1, 8.2) and counted. One exception is inland silverside, which are not separated from Atlantic silverside because they are rare and difficult to identify. Qualitative counts were used for menhaden when abundant ( $\mathrm{n}>1000$ ) to minimize discard mortality. Winter flounder are measured to total length (mm), and classified as young-of-year (YOY) if less than 12 cm and age $1+$ if 12 cm or larger. The age of flounder near this size was verified in 1990-1992 by examination of the sagittal otolith. Physical data recorded at each seine location included water temperature and salinity at one-meter depth. The geometric (retransformed natural $\log$ ) mean catch per standard haul is calculated for total finfish catch and individually for the 22 most abundant species, with separate indices for young-of-year (YOY) and winter flounder age 1 and older. Winter flounder YOY catch is also reported for each site. Confidence intervals (95\%) for each geometric mean are retransformations of the corresponding log intervals. Frequency of occurrence is given as a percentage of all samples taken each year.

Diversity in the catch, or species richness, was computed for finfish species captured in the Survey over the time series. Species were divided into three groups based on their temperature preferences and seasonal spawning habits as documented in the literature.

Criteria used to assign species into a cold temperate group, warm temperate group, or subtropical group are listed in Job 5.

## RESULTS

A total of 48 seine hauls were taken in 2016 at eight sites, yielding a total catch of 13,466 fish of 28 species and 16,072 invertebrates of 17 species. Geometric mean catch of all finfish ( 159 fish/haul) was above the 29 -year time series median of 139 fish/haul (Figure 8.2). Although total catch has varied considerably year to year, the increasing trend is significant ( $\mathrm{df}=28, \mathrm{r}^{2}=0.11, \mathrm{p}=0.048$ ). Dominant species contributing to this increase include young-of-year (YOY) black sea bass, tautog, scup (porgy), northern kingfish, striped searobin, and menhaden.

Geometric means were calculated for 22 species commonly captured since the survey began in 1988 (Table 8.1). The most frequently caught species was Atlantic silverside, which occurred in all samples, followed by black sea bass, striped killifish, tautog, snapper bluefish and northern pipefish (Table 8.2). This rank order has changed from previous years, with a notable decrease in winter flounder YOY (Figure 8.3) grubby, and windowpane flounder.

Scup, snapper bluefish, black sea bass and northern kingfish occurrence and abundance showed a marked increase above the 28 year time series average in 2015, with record high abundance for the time series (Tables 8.1 and 8.2). Occurrence of striped searobin and inshore lizardfish also ranked high in the time series. Windowpane flounder remained absent in 2015 after low abundance was observed in 2011 and 2014, and no presence recorded in 2009-10 and 2012-13 (Table 8.1).

## Relative Abundance of Juvenile Winter Flounder and Tautog

The 2016 index of YOY winter flounder ( 0.6 fish/haul) is similar to the 2015 index and continued a modest increase from the record low abundance observed in 2013 (Table 8.3, Figure 8.3). The time series has a significant negative trend ( $\mathrm{r}^{2}=0.36, \mathrm{p}<0.001, \mathrm{df}=28$ ), and indicates that a relatively strong year class has not been produced since 1996 (Table 8.1, Figure 8.3). As in previous years, highest abundance was seen at eastern sites (Groton, Waterford, Old Lyme) and Greenwich. Three of the eight sites had no catch (Table 8.3) and the frequency of occurrence of this species has decreased over the time series (Figure 8.3) indicating that juvenile production has contracted in several areas of the Sound. Mean length of YOY winter flounder captured at all sites in 2016 was 59.9 mm and shows no trend over the 29 -year time series, ranging from 47.3 to 71.1 mm .

The 2016 index of YOY tautog ( 1.1 fish/haul) was near to near the series average of 1.0 tautog /haul, a decline from 2015, the highest abundance in the time series (Table 8.1, Figure 8.4). Overall, the time series has a significant increasing trend $\left(\mathrm{r}^{2}=0.25, \mathrm{p}=0.004\right.$, $\mathrm{df}=28$ ). Relatively abundant year classes have been produced in 1998-1999, 2002-2004, 2007-2008, 2012 and 2014-2015. The frequency of occurrence of this species has also
increased over the time series (Figure 8.4) indicating that juvenile production and survival is improving in several areas of the Sound.

## Presence of Other Important Recreational Finfish

YOY scup and black seabass are recent additions to the seine survey (Table 8.1, Figures 8.5 and 8.6). Scup occurred in 1999 but the highest relative abundance has been in the last five years of the time series. In 2015 the species was present in record numbers and the 2016 index ( 1.3 fish/haul) remains above the time series mean ( 0.8 fish/haul).

YOY black sea bass first appeared in Survey catches in 1991 and every year since 1998, reaching their record highest recorded abundance in 2015 ( 2.8 fish/haul). The 2016 index ( 1.9 fish/haul) is the third highest in the time series, behind 2014 and 2015.

YOY bluefish show a pattern similar to black seabass, first appearing in the catch in 1991 and remaining consistent since 1998. Their abundance increased dramatically in 2014 and 2015, returning to average abundance for the time series ( 0.26 fish/haul) in 2016 (Table 8.4)

## Relative Abundance of Forage Species

Seine survey catches are numerically dominated by forage species, defined here as shortlived, highly fecund species that spend the majority of their life cycle inshore where they are common food items for piscivorous fish. An index of forage fish abundance was generated using the catch of four of the most common forage species caught: Atlantic silverside, striped killifish, mummichog, and sheepshead minnow (Figure 8.7). The 2016 index ( 99 fish/haul) was near the mean ( 98 fish/haul) for the time series, decreasing from the 2015 index which was the second highest.

Although numerically driven by the abundance of silverside, all four forage fish species increased in abundance and occurrence in 2015 and were at or above their time series mean in 2016. Over the 29 year time series, the forage index has shown considerable variability, common for short-lived forage species, with no significant trend (( $r^{2} 0.06$, $p=0.12$, Figure 8.7).

## Relative Abundance of Invertebrate Species

A total of 16,068 invertebrates comprised of 16 species were captured in 2016 (Table 8.6, Appendix 8.2), similar to 2015 . Six crab species were present in the seine hauls, along with three shrimp species, one gastropod and one bivalve. Mud snail, sand shrimp, shore shrimp, green crab, and hermit crab were the most abundant and were observed more than $50 \%$ (Table 8.3).

Blue crabs were captured in the Groton, Waterford, Clinton and Milford sites at relatively low abundance in 2016 ( $\mathrm{n}=6$ crabs) down from a time series high in 2009 ( $\mathrm{n}=333$ crabs). A single Asian shore crab was observed in the Old Lyme site in 2016. The shore shrimp returned to moderate abundance in 2016, after increasing substantially in 2014-2015, while sand shrimp decreased significantly (Table 8.3). Spider crab abundance has also increased nearly ten-fold since 2011 compared to earlier years, with the highest catch observed in 2016.

## Finfish Species Richness

Over the 29 -year time series, the mean number of cold temperate species captured per seine haul (Figure 8.8, Table 8.7) shows a negative trend ( $\mathrm{r}^{2}=0.20, \mathrm{p}=0.01$ ). In contrast, the mean number of warm temperate species captured per haul has increased significantly ( $\mathrm{r}^{2}=0.61, \mathrm{p}<0.001$ ), from about three to more than seven over the time series.

## MODIFICATIONS

None.

Table 8.7: Cold and warm temperate species captured in the Estuarine Seine Survey.

| Cold Temperate |  |
| :--- | :--- |
| Common name | Species <br> Scientific Name |
| alewife | Alosa pseudoharengus |
| American sand lance | Ammodytes americanus |
| Atlantic tomcod | Microgadus tomcod |
| cunner | Tautogolabrus adspersus |
| grubby | Myoxocephalus aeneus |
| little skate | Leucoraja erinacea |
| northern pipefish | Syngnathus fuscus |
| rock gunnel | Pholis gunnellus |
| rainbow smelt | Osmerus mordax |
| winter flounder | Pseudopleuronectes <br> americanus |
| windowpane flounder | Scophthalmus aquosus |

| Warm Temperate Species |  |
| :---: | :---: |
| Common name | Scientific Name |
| American eel | Anguilla rostrata |
| American shad | Alosa sapidissima |
| Atlantic silversides | Menidia menidia |
| bay anchovy | Anchoa mitchilli |
| blueback herring | Alosa aestivalis |
| black seabass | Centropristis striata |
| bluefish | Pomatomus saltatrix |
| butterfish | Peprilus triacanthus |
| feather blenny | Hypsoblennius hentz |
| gizzard shad | Dorosoma cepedianum |
| hogchoker | Trinectes maculates |
| lined seahorse | Hippocampus erectus |
| menhaden | Brevoortia tyrannus |
| naked goby | Gobiosoma bosci |
| northern kingfish | Menticirrhus saxatilis |
| northern puffer | Sphoeroides maculates |
| northern searobin | Prionotus carolinus |
| northern stargazer | Astroscopus guttatus |
| oyster toadfish | Opsanus tau |
| pumkinseed | Lepomis gibbosus |
| scup | Stenotomus chrysops |
| silver perch | Bairdiella chrysoura |
| smooth dogfish | Mustelus canis |
| smallmouth flounder | Etropus microstomus |
| spotted hake | Urophycis regia |
| spot | Leiostomus xanthurus |
| striped searobin | Prionotus evolans |
| striped anchovy | Anchoa hepsetus |
| striped bass | Morone saxatilis |
| summer flounder | Paralichthys dentatus |
| tautog (blackfish) | Tautoga onitis |
| white perch | Morone Americana |
| weakfish | Cynoscion regalis |

Figure 8.1: Sampling locations of the Estuarine Seine Survey.

Figure 8.2: Mean catch of all finfish captured in seine samples, 1988-2016. Geometric mean catch (numbers) per haul includes samples at all sites. Note that sampling at the Milford site began in 1990.

Figure 8.3: Mean catch and occurrence of young-of-year winter flounder, 1988-2016. Confidence intervals (95\%) are shown (dotted lines). The negative trend (dashed line) is significant ( $r^{2}$ $=036, p<0.001, d f=28$ ). Percent of hauls catching winter flounder (shaded bars) has also decreased.

Figure 8.4: Mean catch and occurrence of young-of-year tautog, 1988-2016. Confidence intervals (95\%) are shown (dotted lines). The positive trend (dashed line) is significant ( $r^{2}=0.25$, $p=0.003, d f=28$ ). Percent of hauls catching tautog (shaded bars) has also increased.

Figure 8.5: Mean catch of black seabass young-of-year, 1988-2016. Annual percent of hauls catching one or more black seabass are also shown.

Figure 8.6: Mean catch of scup young-of-year, 1988-2016. Annual percent of hauls catching one or more scup are also shown.

Figure 8.7: Mean catch of forage fish, 1988-2016. Forage species included in the index are Atlantic silversides, mummichog, sheepshead minnow, and striped killifish. Confidence intervals (95\%) are shown (dotted lines) and annual geometric mean catch is shown in boxes below. See Appendix 8.1 for complete taxonomic names.

Figure 8.8: Trend in species richness for cold and warm temperate species at eight seine sites, 1988-2016. See Table 8.7 for species listings by group.

## JOB 9: Volunteer Estuarine Fisheries Database

## GOAL

Identify estuarine near-shore waters critical to the production and growth of recreationally important finfish for the purpose of protecting and enhancing these populations in shallow water habitats and promote citizens' greater understanding and appreciation of local marine resources through participation in local volunteer survey projects.

## OBJECTIVES

1) Provide reliable indices of relative abundance for finfish and key water quality measurements by standardizing samples taken in Connecticut near-shore waters by local volunteers.
2) Document the occurrence of uncommon or rare species and their distribution by habitat type in order to determine their vulnerability to local extinction due to human activities and/or climate change.
3) Provide location-specific size, growth and movement data for recreationally important species to inform immediate and long-term local, regional, and interstate assessments and management plans.
4) Develop and maintain a state-wide fisheries database of all volunteer survey programs in order to maximize their usefulness to all citizen groups, educational programs, municipalities, statewide regulatory programs and interstate management plans.

## INTRODUCTION

Several citizens' groups formed in response to CT DEEP educational programs, as well as to address local environmental issues, have spent thousands of volunteer hours gathering fisheries abundance data and accompanying water quality information. This job was developed as a mechanism for establishing a flexible data framework where volunteer datasets can be collated, standardized, and accessed. This database should provide data useful for protecting the state's near-shore estuarine ecosystem which is particularly vulnerable to physical flux and alternation or degradation due to human activities.

## METHODS

Data were obtained from citizen groups that have gathered fisheries abundance and water quality data for more than a decade. Based on interviews with the groups' leaders, these data were collated into the Volunteer Estuarine Fisheries Database and synthetic summaries were made for purposes of comparison. For each program, a matrix was generated in Excel or Access software documenting the date, location, and quantity of each species captured in their sampled area by gear type. The total number of each finfish species was computed as a percentage of the total finfish captured by year. Additionally, movement data for tautog (Tautoga onitis) within Long Island Sound were obtained from a cooperative volunteer tagging study. Release and return data (location, date, name of tagger and person reporting return) are archived at the CT DEEP Marine Fisheries Office in annual Excel spreadsheets and GIS shape files.

## Harbor Watch Norwalk Harbor Survey

Harbor Watch, a Program sponsored by Earth Place Nature Center in Westport CT, has run a beam trawl survey in the Norwalk River since 1990. The program was initiated under the guidance of Richard Harris, Program Director, and CT DEEP Fisheries Division staff, and continued in 2015-16 under Program Director Sarah Crosby. The sampling program divides the saline portion of the river into 20 fishable grids which overlap previously established water quality sampling stations (Figure 9.1). Benthic finfish and invertebrates are captured using a onemeter beam trawl ( 0.63 cm mesh net) towed for 5 minutes within one of the sample grids (Harris et al. 2014). Samples are made at least weekly at grids representing upper, middle, and lower reaches of the river. Sampling is accomplished with the help of students from Wilton High School.

## Coast Guard Academy Thames River Survey

The academic curriculum of the US Coast Guard Academy has included biological sampling of the Thames River since the 1970s. Samples are taken in the Thames River from the Gold Star Bridge upriver to the Naval Submarine Base (Figure 9.3). Shallow (5-10m depth) and channel ( $12-15 \mathrm{~m}$ depth) tows are made one day per week from August to October with a 9.15 m flat trawl net (\# 15 twine, 5.10 cm stretch mesh, \#21 twine codend with 1.27 cm mesh and 0.95 cm liner; Mrakovcich, personal communication, 2015). The same gear and manual deployment technique has been used over the years, however the vessel changed in 2013. Tow duration was 10 minutes in 1974-2006 and changed to the equivalent 0.5 km in 2007-2015.

## Tautog Tagging Study

The Recreational Fishing Alliance (RFA) and the University of Connecticut initiated a cooperative tautog tagging study with the assistance of CT DEEP Fisheries Division staff to learn more about the migratory range, timing, and habits of this species. American Littoral Society tags were used to take advantage of the broadly established tag recognition this program has, the simplicity in tag method being designed for use by fishermen, and the cost effectiveness of ALS tag report management. Tagging operations are designed to begin as soon as practicable in the spring and early summer to take advantage of spawning aggregations both for efficiency and to allow tagged fish to randomly mingle into the greater population prior to post-spawn dispersal during feeding excursions. Beginning in spring 2015, tautog were tagged with American Littoral Society (ALS) yellow "spaghetti" fish tags. All ALS tags are labeled with a unique six digit tag number and the message "RETURN LITTORAL SOC. HIGHLANDS, NJ 07732."

## RESULTS

## Harbor Watch Norwalk Harbor Survey

From 1990-1994, the Harbor Watch program documented an abundance and high diversity of benthic fish (Table 9.1). The largest concentrations of the target species, juvenile winter flounder, were captured from the I-95 Bridge south to the Maritime Center (grids A-D, Figure 9.1, Harris et al. 2014). From 1995-2005 comparable surveys were not performed due to necessary boat repairs and sampling outside Norwalk Harbor. Extensive dredging began in the upper harbor in 2005-2006. Limited sampling occurred in 2007 and resumed to a full program in 2008. Beam trawl sampling captured 5-15 finfish species annually for years with comparable
effort in June through October (Table 9.1). Average catch abundance in 2016 ( 0.9 fish/tow) was the third lowest, following the modest increase reported in 2015. The total number of species captured in 2016 (12) was among the highest. In 2016, winter flounder were only captured in 9 out of 19 grids sampled, considerably lower than 2015 when the species was captured in 18 of the 19 grids sampled and their number/tow were the highest recorded since 2005. As opposed to 2015 when flounder were most abundant in the lower harbor (Box L, Figure 9.1, Crosby et al. 2015), highest catch in 2016 was distributed between mid-harbor sites (Boxes C, D, E) and the lower harbor (Boxes P and T). Distributions in 2015 and 2016 differed from the early 1990s when the species were most abundant in the upper harbor.

Bottom water temperatures taken weekly at six stations in the Norwalk River beginning in 1987 (Figure 9.1) show a clear warming trend for years with complete sampling during summer, JulySeptember (Figure 9.3). Warming was greatest in the upper river (Stations 1 and 1a), and all stations combined show a positive slope of approximately $1.1^{0} \mathrm{C}\left(2.0^{\circ} \mathrm{F}\right)$ over the time period.

## Coast Guard Academy Thames River Survey

The Academy marine science class surveys of the Thames River are documented beginning in 1974 (Table 9.2). Annual surveys varied from 4-18 otter trawl tows. Finfish were captured in all samples (i.e., $100 \%$ positive tows). Mean catch in trawl samples varied from 2.9-12.0 fish/tow without trend while total species captured ranged from 7-32 annually with a slight increase in recent years. Windowpane and winter flounder dominated the catch in the beginning of the time series, but were replaced by summer flounder, scup, and butterfish in later years.

## Tautog Tagging Study

Eighteen volunteer anglers tagged and released 353 tautog in 2015 (Figure 9.4), and 144 tautog in 2016 (figure 9.5). Of fish tagged in 2015 by these volunteers and through the American Littoral Society fish tagging program, 28 were recaptured. These recaptured fish were at-large between 1 and 141 days, with an average time at-large of 60 days. Most fish were recaptured on the same grounds they were first tagged. However, two recaptured fish did show notable movement, one that moved from the Housatonic area to Clinton. Importantly, another fish atlarge just 13 days after being tagged in late October was recaptured in New York waters near Race Rock (Fishers Island), demonstrating some degree of shared resource between New York and Connecticut state waters. An additional fish tagged in 2015 was recaptured the following spring in the same location as it was tagged (Kelsey Point, Clinton) after 189 days at large.

Forty-eight of the 144 tautog tagged in 2016 were tagged and released by personnel at the Millstone Environmental Laboratory off Two Tree Island in eastern Long Island Sound. Five of these fish were recaptured in 2016 at the same location after being at large for 8-34 days (mean $=$ 23 days). Two additional tautog, tagged by recreational anglers in 2016 near Southwest reef off Westbrook, were recaptured in the vicinity within a month of initial tagging. While there were some notable distances traveled by individual fish, the large majority of recaptured tautog have been taken in the same general area where they were released.

## MODIFICATIONS

The Tautog Tagging Study will continue in 2017. Data collection from other volunteer groups will be discontinued due to limitations on Fisheries staff time.

JOB 10: COOPERATIVE INTERAGENCY RESOURCE MONITORING

# 2016 Long Island Sound Hypoxia Season Review 

Connecticut Department of Energy \& Environmental Protection
79 Elm Street, Hartford, CT 06106
Robert J. Klee, Commissioner

Interstate Environmental Commission 2800 Victory Boulevard, Building 6S Room 106

College of Staten Island-CUNY Campus
Staten Island, NY 10314

## Introduction

Designated as an estuary of national significance by Congress in 1987, Long Island Sound is home to a diverse network of flora and fauna and over 4 million people. It is an estuary of recreational, commercial, and socioeconomic value. The Sound is bordered by the states of Connecticut and New York and has a watershed area extending through Maine and Quebec that encompasses over 16,000 square
 miles and 9 million people. Over time, the Sound has been subject to the effects of increased nutrient loading as a result of urbanization and changes in land use (Latimer et al., 2014). Seasonal weather patterns, particularly during the summer months, exacerbate the effects of nutrient loading, causing hypoxic conditions in the Sound, most prominently in the Western Basin. This, in turn, negatively impacts the water quality of this estuary, the ecosystem services and resources it provides, and the habitat that is home to its many species. In response to the critical need to document summer hypoxic conditions in Long Island Sound and its embayments as defined in the Long Island Sound Study's Comprehensive Conservation and Management Plan, the Connecticut Department of Energy and Environmental Protection (CT DEEP) and the Interstate Environmental Commission (IEC), have monitored dissolved oxygen, as well as key water quality parameters relevant to hypoxia, in Long Island Sound since 1991.

This report presents a summary of in situ data collected by CT DEEP and IEC during the 2016 hypoxia season. The hypoxia season is defined as June-September. Data from the Long Island Sound Integrated Coastal Observing System (LISICOS) are presented with permission for informational purposes. Sampling and analyses were conducted under EPA-approved Quality Assurance Project Plans.

The CT DEEP and IEC Long Island Sound (LIS) Water Quality Monitoring Programs are synoptic in nature and are intended to characterize water quality conditions at one moment in time over a broad area (the entire Sound). Both programs support long term monitoring databases designed to detect changes in hypoxia due to changing conditions (e.g., management actions, climate change, productivity). Both programs also provide data (e.g. nutrient, BOD, TSS, chlorophyll a) not currently available from fixed station buoy applications. In addition, CTDEEP provides limited biological data (plankton communities).

The LISICOS water quality sensors are attached to fixed locations and provide a holistic view of the conditions over a more detailed span of time (i.e., data measured every 15 minutes from one station as opposed to every two weeks). The LISICOS continuously recording buoys have shown instances where vertical mixing within the water column raises the DO concentrations above the hypoxic threshold of 3.0 milligrams per liter ( $\mathrm{mg} / \mathrm{L}$ ) for extended periods of time (e.g., days). These episodic conditions are not captured by CT DEEP or IEC surveys.

As such, CT DEEP and IEC data provide a snapshot of hypoxic conditions at one time while the LISICOS data provide a continuous measurement of hypoxia at specific buoy locations. Together these monitoring programs are better able to characterize the extent and duration of hypoxia across LIS. Both types of data contribute to a better understanding of hypoxia in LIS.

## What is Hypoxia?

The term "hypoxia" means low dissolved oxygen ("DO") concentrations in the water. Marine organisms need oxygen to live, and low concentrations, depending on the duration and the size of the area affected, can have serious consequences for a marine ecosystem. As defined by the Long Island Sound Study, hypoxia exists when DO drops below a concentration of $3 \mathrm{mg} / \mathrm{L}$, although research suggests that there may be adverse effects to organisms even above this level, depending upon the length of exposure (EPA, 2000 and Simpson et al., 1995). The Connecticut Department of Energy \& Environmental Protection, the New York State Department of Environmental Conservation and the Interstate Environmental Commission have water quality criteria for dissolved oxygen. These criteria, designed to protect the state's waters from degradation, define hypoxia as DO concentrations below $3.0 \mathrm{mg} / \mathrm{L}$. Low oxygen levels can occur naturally in estuaries during the summer, when calm weather conditions prevent the mixing of the water column that replenishes bottom water oxygen during the rest of the year. However, excess nitrogen tends to exasperate hypoxia beyond that which may be caused by natural conditions.

## How Does Low Oxygen Impact the Sound?

Each summer low oxygen levels render hundreds of square miles of bottom water unhealthy for aquatic life.
Dissolved oxygen levels follow seasonal patterns with a decrease in bottom water DO over the course of the summer. Hypoxic conditions during the summer are mainly confined to the Narrows and Western Basin of Long Island Sound (map right). Those areas comprise the section of the Sound west of a line from Stratford, CT to Port Jefferson, NY. The maximum extent of the hypoxic condition typically occurs in early August.

EPA, NY and CT implemented the Total Maximum Daily Load to Achieve Water Quality Standards for Dissolved Oxygen in Long Island Sound (2000 TMDL) which has resulted in significant progress in reducing open water Sound hypoxic conditions. Across Connecticut and New York, 106 wastewater treatment plants have been upgraded and 40 million fewer pounds of nitrogen have entered the Sound (51.5\% reduction).

EPA estimates a $40 \%$ reduction in the five year rolling average area of hypoxia across the Sound, compared to pre-TMDL levels (EPA 2015).

The maps in the sidebar display the percentage of years when dissolved oxygen concentrations at each station were below $3.0 \mathrm{mg} / \mathrm{L}$ in the bottom waters of Long Island Sound in five year intervals. The maps show the area of hypoxia reducing in the Western Sound (Stations 09, E1, D3), but continuing to persist in the Narrows (Stations A4, B3, C1). The maps are based on CT DEEP monitoring data only. Updates to hypoxia maps combining IEC and CT DEEP data have not been completed for years prior to 2016.

Percent of Hypoxic Years with DO Concentrations $<3.0 \mathrm{mg} / \mathrm{L}$

## Habitat Impairment Associated With Hypoxia

The following description of the "Biomass Area-Day Depletion (BADD) index of habitat impairment was excerpted from an article written by CT DEEP Marine Fisheries Biologist Penny Howell for the July/August 2014 edition of CT Wildlife Magazine.

For Long Island Sound, DO levels below $3 \mathrm{mg} / \mathrm{L}$ are considered hypoxic, causing mobile animals to leave and sessile animals to die or be physically or behaviorally impaired. However, $D O$ can become limiting below $4.8 \mathrm{mg} / L$ for sensitive fish species, such as whiting and scup, while more tolerant species, such as butterfish, bluefish, lobster and Atlantic herring, are not affected until DO falls below $2 \mathrm{mg} / \mathrm{L}$ (Simpson et al, 1995, 1996).

An index of habitat impairment, "Biomass Area-Day Depletion" (BADD) was developed by CT DEEP Marine Fisheries Division based on extensive sampling in the Sound from 1986-1993 (Simpson et al, 1995,1996). Instead of individual species' responses to low oxygen, an aggregate response of 18 demersal (bottom-dwelling) finfish species was calculated as a general index of the impact on living resources to low oxygen conditions at or near the bottom of the Sound. The total weight, or biomass, of these demersal finfish species captured in samples taken at various levels of low DO was quantified and the percent reduction in biomass from that captured in fully oxygenated water was computed. These studies showed that the finfish biomass is reduced by $100 \%$ (total avoidance) in waters with DO less than $1.0 \mathrm{mg} / \mathrm{L}$. In waters with $1.0-1.9 \mathrm{mg} / \mathrm{L}$ DO, biomass is reduced by $82 \%$, while a $41 \%$ reduction occurs at 2.0-2.9 $\mathrm{mg} / \mathrm{L} D O$, and a $4 \%$ reduction occurs at 3.0-3.9 mg/L DO (Simpson et al, 1995, 1996).

For each survey the total area of the Sound encompassing each 1-mg interval of DO is calculated and the depletion percentage applied. These area depletions are summed over the number of days they persist during the designated hypoxia season. The summed area-day depletion is then expressed as a percentage of the total available area (total sample area of $2,723 \mathrm{~km}^{2}$ ) multiplied times the total season (94 days). A maximum BADD index of $100 \%$ would result from severe hypoxia occurring over the entire study area for the entire hypoxia season.

In an average year, hypoxic waters cover $\sim 440 \mathrm{~km}^{2}\left(169\right.$ miles $\left.{ }^{2}\right)$ for 55 days and result in a BADD impairment index of $2.5 \%$. In the worst year (1994), hypoxia spread over $1,000 \mathrm{~km}^{2}$ (395 miles ${ }^{2}$ ) for the entire season, resulting in a BADD index of almost $9 \%$. In 2016, the BADD index was $3.05 \%$ up from $0.77 \%$ in 2015.

## 2016 Summer Weather Conditions

The Northeast Regional Climate Center (NRCC) at Cornell University is tasked with disseminating climate data and information for 12 states. The NRCC included the graphics at the left in their Eastern Region Quarterly Climate Impacts and Outlook Summary September 2016 (NRRC 2016a).

The summer of 2016 was warm and dry, with this summer being recorded as the second warmest on record for the Eastern region. Across the region, June was $0.8^{\circ} \mathrm{F}$ above normal, July was $2.2^{\circ} \mathrm{F}$ above normal, August was $3.6^{\circ} \mathrm{F}$ above normal, and September was $4.2^{\circ} \mathrm{F}$ above normal. The warmth continued into November where the region as a whole was $2.0^{\circ} \mathrm{F}$ above normal. The average August 2016 air temperatures at climate sites around Long Island Sound ranged from $78.4^{\circ} \mathrm{F}$ in Bridgeport, CT ( $5.1^{\circ} \mathrm{F}$ above normal) to $81.6^{\circ} \mathrm{F}$ at LaGuardia Airport in Queens, NY ( $5.3^{\circ} \mathrm{F}$ above normal) to $77.3^{\circ} \mathrm{F}$ at Islip, NY on Long Island ( $4.5^{\circ} \mathrm{F}$ above normal).

Precipitation was below normal across the Eastern Region for the summer of 2016. At the beginning of June, NRRC noted that only about $1 \%$ of the Northeast was in a drought with the region receiving $89 \%$ of its normal precipitation. By September $37 \%$ of the Northeast was in a moderate, severe, or extreme drought. The lack of precipitation continued into November. Across Long Island Sound, precipitation totals varied widely from site to site and month to month. At Bridgeport, CT, June was very dry with only $35 \%$ of normal precipitation but July was wet with $139 \%$ of normal rainfall; during August and September rainfall was also below normal with $8-\%$ and $78 \%$ or normal precipitation recorded. At LaGuardia Airport in Queens, NY, June was also dry with $57 \%$ of the normal precipitation falling, July was wet ( $111 \%$ of normal), but August was drier than in Bridgeport with only $27 \%$ of normal rainfall amounts recorded. September saw a slight improvement with $68 \%$ of normal precipitation reaching the ground at the Airport. On Long Island at Islip, NY June precipitation amounts were $26 \%$ of normal, July was $94 \%$ of normal, August was $23 \%$ of normal, and September was $85 \%$ of normal.

A Northeast Drought and Climate Outlook Forum was held in Boston in October to discuss the drought situation across the region (NRRC 2016b).

This climate information is useful as physical processes influence the timing and duration of hypoxia.

## CT DEEP Program Overview

Since 1991, the Connecticut Department of Energy \& Environmental Protection (CT DEEP, formerly the Department of Environmental Protection, (CTDEP) has conducted an intensive year-round water quality monitoring program on Long Island Sound (LIS). Water quality is monitored at up to forty-eight (48) sites by staff aboard the Department's Research Vessel John Dempsey. Data from the surveys are used to quantify and identify annual trends and differences in water quality parameters relevant to hypoxia (low dissolved oxygen), especially nutrients, temperature, and chlorophyll. These data are also used to evaluate the effectiveness of the management program to reduce nitrogen concentrations. During the summer (June September) CT DEEP conducts additional summer hypoxia surveys at bi-weekly intervals to better define the areal extent and duration of hypoxia.

## DEP stations in Long Island Sound

## CT DEEP Methods

From October to May, in situ data and nutrient samples are collected once a month from 17 sites. Bi-weekly hypoxia surveys start in mid-June and end in September with up to 48 stations being sampled during each survey for in situ parameters.

Dissolved oxygen, temperature, pH , and salinity data are collected in situ (on site in the water column) using an electronic instrument called a Conductivity Temperature Depth recorder (CTD) that takes measurements from the surface to the bottom of the water column. The CTD, a Sea-Bird model SBE-19 SeaCat Profiler equipped with auxiliary dissolved oxygen, photosynthetically-active radiation (PAR) and pH sensors, is attached to a Rosette Sampler and lowered through the water column at a rate of approximately 0.2 meters per second and measurements are recorded every 0.5 seconds. In situ data are reviewed in
 real-time.

Water samples are collected using Niskin water sampling bottles that are attached to the Rosette Sampler. The Rosette is lowered off the stern of the Dempsey and the bottles are triggered remotely to take a water sample at any specified depth (surface $=2$ meters below the surface; and bottom $=5$ meters above the bottom). Samples are filtered aboard the mini laboratory and preserved for later analyses at the University of Connecticut's Center for Environmental Science and Engineering in Storrs, Connecticut.

Parameters for which surface and bottom waters are tested include dissolved silica, particulate silica, particulate carbon, dissolved organic carbon, dissolved nitrogen, particulate nitrogen, ammonia, nitrate + nitrite, particulate phosphorus, total dissolved phosphorus, orthophosphate, chlorophyll a, and total suspended solids.

Since 2002, CT DEEP has collected zooplankton samples from six stations and phytoplankton from ten stations across Long Island Sound. The samples are sent to researchers at the University of Connecticut who identify species composition, abundance, community structure, and spatial and temporal distribution throughout the Sound.

All samples are collected and analyzed under EPA-approved Quality Assurance Project Plans.

## IEC Program Overview

The Interstate Environmental Commission (IEC) is a tri-state water and air pollution control agency located in Staten Island, NY on the College of Staten Island campus. Established in 1936, the IEC serves the states of New York, New Jersey, and Connecticut. The IEC's area of jurisdiction runs west from New Haven, CT, and Port Jefferson, NY, on Long Island Sound. As of 2012, IEC has been in a temporary host relationship with the New England Interstate Water Pollution Control Commission (NEIWPCC).

IEC has conducted monitoring in the far Western Long Island Sound and the Upper East River since 1991. IEC's monitoring program was designed to align with CT DEEP's program. The overall goal of IEC's seasonal monitoring program is to effectively measure key water quality indicators identified by the Long Island Sound Study (LISS), such as hypoxia and nutrient pollution, which are important for managing priority areas of concern.

IEC's monitoring program is conducted between June and September as dissolved oxygen concentrations in Long Island Sound typically reach their lowest levels during the summer. This allows for better characterization of hypoxia and identification of critical areas in the Sound. Between June and September, IEC collects in situ data from 22 stations in the Western portion of the Sound on a weekly basis. In situ parameters include water temperature, dissolved oxygen, salinity, pH , and water clarity (secchi disk depth). In addition, IEC collects biweekly samples for chlorophyll a, Biochemical Oxygen Demand (BOD), Total Suspended Solids (TSS), and a suite of nutrient parameters. More information about IEC and its monitoring program can be found below or on the IEC website: (http://www.iec-nynjct.org).

IEC monitoring data incorporated in this report for hypoxia maps uses data from 13 of 22 stations. The nine stations not included are representative of embayments. IEC data represented in this report that is not dissolved oxygen data was derived from IEC's six axial stations, which was combined with CT DEEP's seven axial stations. IEC's six axial stations include the following: A1, A2M, A3, A4, A5, B3. CT DEEP's seven axial stations include the following: A4, B3, D3, F3, H4, I2, and M3. Additional IEC data can be derived from IEC's weekly season summaries.

## IEC Methods

Dissolved oxygen, temperature, salinity, and pH data are collected using a YSI EXO 1 Multiparameter Sonde at bottom, mid, and surface depths at all 22 stations on a weekly basis from June through September. For stations with a depth of less than 10 meters, only surface and bottom measurements are collected. In addition, data collection includes percent cloud cover, sea state, water clarity as measured by Secchi disk depth as well as weather and precipitation data.

Surface grab samples (within one meter of the surface) are collected on a biweekly basis June through September for chlorophyll a and Total Suspended Solids (TSS) at all 22 stations and a suite of nutrient parameters and Biochemical Oxygen Demand (BOD) at 11 of the 22 stations. The map below highlights where sample collection takes place and for which parameters. Samples collected for chlorophyll a and TSS are collected directly into a clean, dry, 1000-mL polypropylene sample bottle and are stored in the dark. BOD and nutrient samples are collected using a clean, dry, $2000-\mathrm{mL}$ polypropylene sample bottle. All samples are kept at $\leq 4^{\circ} \mathrm{C}$ during collection and transport to the IEC laboratory. The IEC laboratory is a nationally certified environmental testing laboratory with National Environmental Laboratory Accreditation Program (NELAP) accreditation.

The 11 stations for BOD and nutrient sampling, which was added to the program in 2014, were chosen based on feedback and input from the Long Island Sound Study Water Quality Monitoring Workgroup. The specific nutrient parameters that are analyzed include Ammonia, Nitrate+Nitrite, Particulate Nitrogen, Orthophosphate/DIP, Total Dissolved Phosphorus, Particulate Phosphorus, Dissolved Organic Carbon, Particulate Carbon, Dissolved Silica, and Biogenic Silica.

Chlorophyll a, TSS, BOD and all nutrient parameters (with the exception of Dissolved Organic Carbon and Particulate Carbon) are analyzed in-house at the IEC laboratory. Samples for Dissolved Organic Carbon and Particulate Carbon analysis are subcontracted to the University of Maryland's Center for Environmental Science, Chesapeake Biological Laboratory, Nutrient Analytical Services Laboratory in Solomons, MD. Further information on sampling and analytical methods can be found in the EPA-approved QAPP Ambient Water Quality Monitoring in Far Western Long Island Sound, version 3.0.

## LISICOS

The Long Island Sound Integrated Coastal Observing System (LISICOS) was established in 2003 as a component of a regional/national ocean observing system. The system was conceptualized as part of a water quality monitoring program that combined the traditional shipbased point sampling surveys with continuous, real-time sampling stations. Funding for the program was first provided through the Environmental Protection Agency Environmental Monitoring for Public Access and Community Tracking (EMPACT) grant program and is now provided, in part, by the National Oceanic and Atmospheric Administration.

The initial goal was to develop "a capability to observe and understand the LIS ecosystem and predict its response to natural and anthropogenic changes."

LISICOS monitors water quality parameters (e.g., salinity, temperature, dissolved oxygen, surface waves, photosynthetically available radiation, chlorophyll) and meteorological parameters (e.g., wind speed, direction, barometric pressure, wave height) at up to eight stations across the Sound. Sensors are attached to a moored buoy at various depths (surface, mid, bottom). Data are transmitted every 15 minutes in real-time via satellite where they are stored in a database and uploaded to the LISICOS website:
http://lisicos.uconn.edu/index.php.
The system is maintained by the University of Connecticut.

## 2016 mportant Facts

CT DEEP conducted eight cruises during the summer of 2016 between 10 June and 13 September. Over the course of the season, fifteen (15) different stations were documented as hypoxic and of the 275 site visits completed in 2016, hypoxic conditions were found during three surveys.

IEC conducted twelve cruises during the summer of 2016 between 28 June and 13 September. Hypoxic conditions were found during nine surveys (embayment stations included). 18 different stations were documented as hypoxic.

| Cruise | Start <br> Date | End Date | Number of <br> stations | Number of <br> hypoxic | Hypoxic Area <br> $\left(\mathrm{mi}^{2}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| WQJUN16 | $6 / 8 / 16$ | $6 / 14 / 16$ | 1 | 0 | 0 |

## 2016 Duration Estimates

Start dates and end dates for the hypoxic events are estimated by plotting CT DEEP and IEC data from stations A4 and B3 in an Excel spreadsheet and then using a line with markers chart to interpolate when the DO concentration drops below/rises above $3.0 \mathrm{mg} / \mathrm{L}$. The 2016 hypoxic event was estimated to have begun on July $8^{\text {th }}$. There was a clear period in the beginning of August when DO concentrations rose above $3.0 \mathrm{mg} / \mathrm{L}$ and remained above this threshold for 8 days. This is also evident in data collected by the LISICOS Execution Rocks Buoy (next page). DO concentrations decreased below the hypoxia threshold again on 8 August and remained there for another 28 days, until the fourth of September when concentrations climbed above the 3.0 $\mathrm{mg} / \mathrm{L}$ threshold. Compared to the previous 24 -year average duration of 55 days, 2016 was near average, with the event lasting 51 days.

|  | Event \#1 | Event \#2 | Total |
| :---: | :---: | :--- | :---: |
| Estimated Start Date | $7 / 8 / 2016$ | $8 / 8 / 2016$ |  |
| Estimated End Date | $7 / 30 / 2016$ | $9 / 4 / 2016$ |  |
| Duration (days) | 23 | 28 | 51 |
| Maximum Area (mi2) |  |  | 197.5 |

## Duration Based on Buoy Data Obtained from the LISICOS Network on 29 September 2016

The figure below is from the LISICOS website and depicts the 2016 real-time bottom dissolved oxygen data (blue line); the average of the 10-year dataset (black line); and the variability observed over the historical station record (gray shading) from the Execution Rocks Buoy. The Western Sound Buoy was offline the entire summer after sustaining damage over the winter of 2014-2015.

## Based on LISICOS Buoy Data Collected Between 1 June to 28 September

| Estimated Dates Event \#1 | $7 / 8 / 16-7 / 31 / 16$ |
| :--- | :---: |
| Estimated Dates Event \#2 | $8 / 8 / 16-9 / 5 / 16$ |
| Duration below $3.0 \mathrm{mg} / \mathrm{L}$ (cumulative days) | 37.3 |
| Duration below $2.0 \mathrm{mg} / \mathrm{L}$ (cumulative days) | 12.9 |
| Duration below $1.0 \mathrm{mg} / \mathrm{L}$ (cumulative days) | 0.01 |
| Minimum DO value (mg/L) | 0.98 (17 August) |
| Days with no data |  |

Data obtained from the LISICOS Execution Rocks Buoy Bottom Dissolved Oxygen Prediction Tool webpage (http://lisicos.uconn.edu/do_fcst.php?site=exrx). Duration is calculated by LISICOS by summing the time (in days) of the number of samples where DO was below the specified value (T. Fake, pers comm. 18 October 2012). Data are provisional and subject to change.

Timing and Duration of Hypoxia, DEEP Data 1991-2016

| Year | Estimated Start Date | Estimated End Date | $\begin{gathered} \text { Maximum } \\ \left(\mathrm{mi}^{2}\right) \end{gathered}$ | Duration (days) |
| :---: | :---: | :---: | :---: | :---: |
| 1991 | July 19 | Aug 28 | 122 | 41 |
| 1992 | July 7 | Aug 30 | 80 | 55 |
| 1993 | July 9 | Sept 10 | 202 | 64 |
| 1994 | July 1 | Sept 6 | 393 | 68 |
| 1995 | July 12 | Aug 16 | 305 | 35 |
| 1996 | Aug 10 | Sept 12 | 220 | 34 |
| 1997 | July 27 | Sept 12 | 30 | 48 |
| 1998 | July 5 | Sept 16 | 168 | 73 |
| 1999 | July 2 | Aug 21 | 121 | 51 |
| 2000 | July 2 | Aug 6 | 173 | 35 |
| 2001 | July 10 | Sept 14 | 133 | 66 |
| 2002 | June 25 | Aug 28 | 130 | 65 |
| 2003 | July 5 | Sept 3 | 345 | 61 |
| 2004 | July 20 | Sept 12 | 202 | 55 |
| 2005 | July 14 | Sept 20 | 177 | 69 |
| 2006 | July 6 | Aug 27 | 199 | 53 |
| 2007 | July 16 | Sept 11 | 162 | 58 |
| 2008 | July 3 | Sept 19 | 180.1 | 79 |
| 2009 | July 19 | Sept 1 | 169.1 | 45 |
| 2010 | July 5 | August 13 | 101.1 | 40 |
| 2011 | July 6 | August 28 | 130.3 | 54 |
| 2012 | July 10 | Sept 10 | 288.5 | 63 |
| 2013 | July 8 | Sept 7 | 80.7 | 62 |
| 2014* | July 24 | Sept 9 | 87.1 | 35 |
| 2015 | July 16 | Sept 10 | 38.3 | 57 |
| 2016* | July 8 | Sept 3 | 197.5 | 51 |
| Average | July 12 | Sept 4 | 170.6 | 55 |
| Deviation | $\pm 10$ days | $\pm 12$ days | $\pm 87.8 \mathrm{mi}^{2}$ | $\pm 13$ days |

The table to the left and the graph below display the onset, duration, and end of the hypoxic events from 1991 through 2016. Based on the LISS standard of $3.0 \mathrm{mg} / \mathrm{L}$, the average date of onset was July 12 ( $\pm 10$ days), the average end date was September 4 ( $\pm 12$ days), and the average duration was 55 days ( $\pm 13$ days). The earliest onset of hypoxia (red text) occurred on 25 June 2002 and the latest end date (green text) occurred on 20 September 2005.
The maximum area of hypoxia was 393 square miles (blue text) and occurred in 1994. The longest hypoxic event occurred in 2008 (magenta text) and lasted 79 days.

* In 2014 and 2016 there were clear periods where the DO concentration rose above the $3.0 \mathrm{mg} / \mathrm{L}$ threshold in the early/middle part of August before dipping again during late August and early September.

## Hypoxia Maps

The following maps depict the development of hypoxia based on CT DEEP and IEC data through the 2016 season. Data for all surveys are available upon request.

Beginning with this year's Season Summary Report, readers will notice maps have been created for all IEC surveys and DEEP surveys. Additionally, maps were created that combine DEEP and IEC data into a single map. The following 13 IEC stations were incorporated in the combined maps: A1, A2M, A3, A4, A5, B1S, B2, B3M, B4, H-A3, H-B, H-C, H-C1. As IEC and DEEP share two stations (A4 and B3), the data from these stations were averaged together to create the new combined maps. IEC stations in embayments (i.e., DI1, DI2, 9-409, 9-412, 9-413, E-12, 8-405, 8403 , and H-D) were not included in the combined maps.

While areal estimates were calculated using these combined hypoxia maps and are presented in this report, they are to be considered for informational purposes only. It is inappropriate to utilize the combined areal estimates as the official hypoxic area for 2016 as they are not comparable to the previous 24 years estimates. DEEP is just beginning the process of updating all the areal estimates from 1991 to the present utilizing historical datasets from IEC. Once completed the datasets would again be comparable.

## IEC Run \#1

During the WQJUN16 and HYJUN16 surveys all CT DEEP stations had DO concentrations above $4.8 \mathrm{mg} / \mathrm{L}$; therefore, no maps were produced. During IEC's first sampling run on 28 June, four stations had concentrations below $4.8 \mathrm{mg} / \mathrm{L}$, which are represented above.

## DEEP WQJUL16 and IEC Run \#2

During the WQJUL16 and Run \#2 surveys dissolved oxygen concentrations in the bottom waters of LIS were less than $4.8 \mathrm{mg} / \mathrm{L}$ at four CT DEEP stations- A4, B3, 02, and 15 and five IEC stations- A3, A4, H-B, A5, and H-D.

## IEC Run \#3

During IEC Run \#3 on 12 July, two stations in the far Western Sound exhibited DO concentrations below $3.0 \mathrm{mg} / \mathrm{L}$; four stations were below $3.5 \mathrm{mg} / \mathrm{L}$; and nine stations were below $4.8 \mathrm{mg} / \mathrm{L}$.

## DEEP HYJUL16 and IEC Run \#4

During IEC Run \#4 on 19 July, only one station exhibited DO concentrations above $4.8 \mathrm{mg} / \mathrm{L}$. Two stations (HC and HC-1) were below $2.0 \mathrm{mg} / \mathrm{L}$, three stations were below $3.0 \mathrm{mg} / \mathrm{L}$ and three stations were below $3.5 \mathrm{mg} / \mathrm{L}$. During the DEEP HYJUL16 survey, DO concentrations dropped below 4.8 $\mathrm{mg} / \mathrm{L}$ at 19 stations with one station below $3.5 \mathrm{mg} / \mathrm{L}$ and one station below $3.0 \mathrm{mg} / \mathrm{L}$. DEEP and IEC were coincidentally at Station A4 at the same time on $7 / 19$. Measurements between the two agencies were comparable-DEEP logged a DO concentration of $2.44 \mathrm{mg} / \mathrm{L}$ at 34.4 meters (m) while IEC recorded $2.48 \mathrm{mg} / \mathrm{L}$ at 36.0 m .

## IEC Run \#5

IEC Run \#5 occurred on 26 July DO measurements at nineteen (19) stations were less than 4.8 $\mathrm{mg} / \mathrm{L}$. Of those, three were less than $3.5 \mathrm{mg} / \mathrm{L}$; nine were less than $3.0 \mathrm{mg} / \mathrm{L}$; and one station, A4, was less than $2.0 \mathrm{mg} / \mathrm{L}$. At Station A4 the DO was $1.96 \mathrm{mg} / \mathrm{L}$. Station B3 was at $2.95 \mathrm{mg} / \mathrm{L}$.

## DEEP WQAUG16 and IEC Run \#6

During the DEEP WQAUG16 survey, conditions improved with dissolved oxygen concentrations at all stations above $3.0 \mathrm{mg} / \mathrm{L}$. DEEP stations C2, E1, and F3 lingered below $3.5 \mathrm{mg} / \mathrm{L}$. During IEC Run \#6 only two embayment stations were below $3.0 \mathrm{mg} / \mathrm{L}$ and four stations were less than $3.5 \mathrm{mg} / \mathrm{L}$.

## IEC Run \#7

During IEC Run \#7 on 9 August, DO concentrations at Stations A5 and H-C dropped below 3.0 $\mathrm{mg} / \mathrm{L}$. Four additional stations exhibited DO concentrations below $3.5 \mathrm{mg} / \mathrm{L}$, including Station A4.

## DEEP HYAUG16 and IEC Run \#8

During the HYAUG16 survey, DEEP recorded three stations with DO concentrations less than 2.0 $\mathrm{mg} / \mathrm{L}$, and IEC documented eight stations below $2.0 \mathrm{mg} / \mathrm{L}$. DEEP also logged 12 stations with concentrations less than $3.0 \mathrm{mg} / \mathrm{L}$, and IEC measured DO's less than $3.0 \mathrm{mg} / \mathrm{L}$ at six stations. This would be the height of the hypoxic event. Based on the traditional DEEP map, $197.5 \mathrm{mi}^{2}$ of bottom waters were estimated to have DO concentrations below $3.0 \mathrm{mg} / \mathrm{L}$.

## IEC Run \#9

During IEC Run \#9 on 23 August, conditions rebounded with only 2 stations exhibiting DO concentrations below $2.0 \mathrm{mg} / \mathrm{L}$, compared to eight stations the week before. Five additional stations remained below $3.0 \mathrm{mg} / \mathrm{L}$.

## DEEP WQSEP16 and IEC Run \#10

Hypoxic conditions were recorded in the Western Sound during the WQSEP16 survey and IEC Run \#10. Concentrations at A4 were still below $2.0 \mathrm{mg} / \mathrm{L}$. Four additional stations remained below 3.0 $\mathrm{mg} / \mathrm{L}$ and two more were less than $3.5 \mathrm{mg} / \mathrm{L}$ during the DEEP survey. During the IEC survey six stations remained below $3.0 \mathrm{mg} / \mathrm{L}$ and two additional stations were less than $3.5 \mathrm{mg} / \mathrm{L}$.

## IEC Run \#11

During IEC Run \#11 on 9 September, the bottom waters of Western Long Island Sound showed marked improvement with only six stations below $4.8 \mathrm{mg} / \mathrm{L}$.

## DEEP HYSEP16 and IEC Run \#12

The remnants of Hurricane/Tropical Storm Hermine (August 28, 2016 - September 6, 2016) did not bring much precipitation to Long Island Sound, but sustained winds increased mixing and further alleviated hypoxic conditions. The LISICOS Execution Rocks buoy data showed concentrations climbing above $3.0 \mathrm{mg} / \mathrm{L}$ and staying above $3 \mathrm{mg} / \mathrm{L}$ beginning on or about 3 September. During the IEC Run \#12, Station A4 was less than $3.5 \mathrm{mg} / \mathrm{L}$. During the DEEP HYSEP16 cruise, only one station, H6, was below $3.5 \mathrm{mg} / \mathrm{L}$. Stations A4 and 01, which were sampled on 13 September, remained below $4.8 \mathrm{mg} / \mathrm{L}$.

## AREA ESTIMATES

The peak hypoxic event occurred during IEC Run \#8 and the HYAUG16 cruises between 16 and 18 August. Based on the traditional CT DEEP stations only interpolation, the maximum area was 197.5 square miles. Compared to the previous 24 -year average, 2016 was slightly above average in area. The lowest dissolved oxygen concentration ( $1.37 \mathrm{mg} / \mathrm{L}$ ) documented by CT DEEP during 2016 occurred on 8/16/16 at Station A4. The lowest dissolved oxygen concentration ( $1.42 \mathrm{mg} / \mathrm{L}$ ) documented by IEC during 2016 occurred on $8 / 18 / 16$, also at Station A4. The Execution Rock Buoy also recorded its' lowest reading during this time, $0.98 \mathrm{mg} / \mathrm{L}$ on 8/17.

The maximum areal estimate is still based on the traditional CT DEEP only data to maintain the continuity of the long-term data set and because the entire previous 24 -year dataset has not been re-interpolated using both the CT DEEP and IEC stations.

The tables on the following two pages demonstrate the differences in the areal estimates between using CT DEEP data alone and CT DEEP data combined with IEC data. Differences in areal estimates are attributed to the increase in spatial coverage in the Western Sound. By increasing the spatial coverage, the map interpolation software used to create the maps places less emphasis (weighting) on stations A4 and B3. For example, if one looks at the areal estimates for the peak event, CT DEEP only data provides an estimate of 40.4 square miles of the bottom water with DO concentrations less than $2.0 \mathrm{mg} / \mathrm{L}$. Adding in the IEC data reduces the estimate to 6.8 square miles. Looking at the maps on page 23 helps to further illustrate this. On the IEC only map (top left) one can see that there are 5 stations with concentrations in the $2-2.99 \mathrm{mg} / \mathrm{L}$ range. The CT DEEP only map (top right) uses data from stations A4 and B3, and interpolates that area in the 1$1.99 \mathrm{mg} / \mathrm{L}$ range.

# Area of Dissolved Oxygen Below the Chronic Criterion for Growth and Protection of Aquatic Life for LIS 

Aquatic organisms can be impacted by a combination of low dissolved oxygen concentrations, exposure, and extended duration of the low DO events. CT DEEP established Dissolved Oxygen Chronic Exposure Criteria based on research and data collected by the EPA. A DO concentration of $4.8 \mathrm{mg} / \mathrm{L}$ meets the chronic criterion for growth and protection of aquatic life regardless of the duration.

This chart illustrates the maximum area of bottom waters within Long Island Sound with DO concentrations less than $4.8 \mathrm{mg} / \mathrm{L}$ based on biweekly sampling by CT DEEP. In 2016, the maximum area below $4.8 \mathrm{mg} / \mathrm{L}$ occurred during the HYAUG16 survey and was estimated at 534 square miles. From 1991-2016, the area affected by concentrations less than $4.8 \mathrm{mg} / \mathrm{L}$ averages 591.6 square miles and varies slightly from 414 to 730 square miles.

## Severe Hypoxia

The Long Island Sound Study provides information on LIS hypoxia for inclusion in EPA's Report on the Environment (https://www.epa.gov/aboutepa/about-national-center-environmental-assessment-ncea ) which reports on "the best available indicators of information on national conditions and trends in air, water, land, human health, and ecological systems..." The Report on the Environment uses $2.0 \mathrm{mg} / \mathrm{L}$ as a benchmark to liken conditions in the Gulf of Mexico to LIS. In this report, the term severe hypoxia is used to describe DO $<2.0 \mathrm{mg} / \mathrm{L}$ and is discussed below.

This chart illustrates the maximum area of bottom waters of Long Island Sound with DO concentrations less than $2.0 \mathrm{mg} / \mathrm{L}$. Based on CT DEEP data, in 2016, bottom water dissolved oxygen concentrations were less than $2.0 \mathrm{mg} / \mathrm{L}$ over 40.4 square miles. This is an increase over the past three years, especially over last year when concentrations in the bottom waters never dropped below $2.0 \mathrm{mg} / \mathrm{L}$ (DEEP data). The average area with concentrations less than $2.0 \mathrm{mg} / \mathrm{L}$, calculated from 1991-2016, is $52.7 \mathrm{mi}^{2}$. In 2016, based on CT DEEP estimates, there were 16 days with DO $<2.0 \mathrm{mg} / \mathrm{L}$. At the LISICOS Execution Rocks buoy, there were 12.90 cumulative days below $2.0 \mathrm{mg} / \mathrm{L}$.

In comparison, the 30 -year average size of the hypoxic zone in the northern Gulf of Mexico is roughly $5,312 \mathrm{mi}^{2}$ (larger than the State of Connecticut). The maximum area of the Gulf of Mexico hypoxic zone occurred in 2002 and was estimated at $8,841 \mathrm{mi}^{2}\left(22,898 \mathrm{~km}^{2}\right)$. The 2015 hypoxic zone covered $6474 \mathrm{mi}^{2}\left(16760 \mathrm{~km}^{2}\right)$ and was larger than 2014. The 2016 Gulf of Mexico shelf-wide cruise was cancelled due to major engine problems with the R/V Nancy Foster. Continuously recording dissolved oxygen meters were deployed in the hypoxic zone in mid-June. Following data clean up and QA/QC, these data will be reported on the Gulf of Mexico Hypoxia website at http://www.gulfhypoxia.net/default.asp. The 2016 hypoxia forecast for the Gulf of Mexico released in June predicted the hypoxic zone would cover $6,824 \mathrm{mi}^{2}$ (Turner and Rabalais, 2016).

In LIS, 1994 and 2003 appear to be years when severe hypoxia ( $\mathrm{DO}<2.0 \mathrm{mg} / \mathrm{L}$ ) was especially prevalent. 1994 had cold winter bottom water temperatures and an unusually warm June which led to strong stratification. The highest average Delta T in July 1994 was $8.54^{\circ} \mathrm{C} .2003$ was the second hottest summer since 1895 and the $28^{\text {th }}$ wettest which also led to the Sound being strongly stratified. Strong stratification (Delta T greater than $4^{\circ} \mathrm{C}$ ) lasted for four months in 1994 (MayAugust) and only one month (July) in 2003.

For management purposes, the Long Island Sound Study defines anoxia as DO concentrations less than $1 \mathrm{mg} / \mathrm{L}$. This chart illustrates the maximum area of bottom waters in LIS with DO concentrations less than $1.0 \mathrm{mg} / \mathrm{L}$ based on biweekly sampling by CT DEEP.

In 13 of the past 26 years, there was no anoxia reported by CT DEEP. It is important to note that IEC and LISICOS have documented anoxic conditions during years when CTDEEP has not. In 2009 and 2010, IEC documented two stations that were anoxic. In 2011, the LISICOS Execution Rocks buoy (Station A4) captured a minimum DO of $0.61 \mathrm{mg} / \mathrm{L}$.

Prior to 2002, the average area of bottom waters affected by anoxia was $5.9 \mathrm{mi}^{2}$. From 20022008 the average area affected was $32.4 \mathrm{mi}^{2}$. From 2009 to 2016, the average area affected was $2.2 \mathrm{mi}^{2}$. The overall average area affected from 1991-2016 is $12.4 \mathrm{mi}^{2}$. The greatest area with DO below $1 \mathrm{mg} / \mathrm{L}$ ( 62 square miles) was during the summer of 2003 .

## WATER TEMPERATURE AND HYPOXIA

In LIS, water temperature plays a major role in the ecology of the Sound especially in the timing and severity of the summer hypoxia event. IEC's monitoring program records water temperature and salinity data weekly from June to September while CT DEEP's monitoring program records water temperatures and salinity year-round. Data collected during IEC's weekly summer surveys and CT DEEP's hypoxia monitoring cruises are used to help estimate the extent of favorable conditions for the onset, extent, and end of the hypoxic event. The conceptual diagram below, while developed for Chesapeake Bay, applies to Long Island Sound. In LIS, there are two key contributors to hypoxia: nutrient enrichment and stratification. (Stratification is discussed more on page 24.) Nutrients, especially nitrogen, flow into the Sound from numerous sources including point sources like wastewater treatment plants and nonpoint sources such as stormwater runoff. This enrichment leads to excessive growth of phytoplankton, particularly in the spring. Temperature can stimulate or impede phytoplankton growth. As the plankton die, they begin to decay and settle to the bottom. Bacterial decomposition breaks down the organic material from the algae, using up oxygen in the process.

## DEEP Water Temperature Data

2016 maximum, minimum, and average water temperature $\left({ }^{\circ} \mathrm{C}\right)$ data are summarized below. Data are integrated across Long Island Sound (i.e., all stations and all depths) and are displayed by cruise. Data were obtained using the CT DEEP Sea Bird Sea Cat Conductivity, Temperature, Depth (CTD) profiler. The Sound is coldest during February and March and warmest during August and September.

The yearly average surface and bottom temperature of the Sound show slight increases over the period 1991-2016

These box and whisker plots show the median water temperature, range, interquartile range, and outliers by cruise from 2008-2016 compared to the 2016 cruise. Water temperatures during the summer of 2016 mimicked air temperatures and were generally above the 2008-2016 medians.

## Historical IEC Water Temperature and Hypoxia Data

1991-2016 average summer (June-September) temperatures $\left({ }^{\circ} \mathrm{C}\right)$ for surface and bottom depths in Western Long Island Sound are summarized below in addition to percentage of hypoxic measurements.

| Year | Mean Summer Temp. $\left({ }^{\circ} \mathrm{C}\right)$ |  | $\begin{gathered} \text { Mean } \\ \Delta \mathrm{T}\left({ }^{\circ} \mathrm{C}\right) \end{gathered}$ | $\underset{(\mathrm{mg} / \mathrm{L})}{\text { Mean Summer DO }}$ |  | \% Hypoxic Measurements (DO $<3.0 \mathrm{mg} / \mathrm{L}$ ) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Surface | Bottom |  | Surface | Bottom | Surface | Bottom |
| 1991 | 22.2 | 21.5 | 0.65 | 6.47 | 4.21 | 0 | 24.2 |

## Delta T and Stratification

The temperature difference between the bottom waters and the surface waters is known as "Delta T". This Delta T, along with salinity differences, creates a density difference, or density gradient, resulting in a separation or stratification, of water layers. Stratification hinders the oxygenated surface waters from circulating downward and mixing with the oxygen starved bottom waters. The pycnocline, or zone where water density increases rapidly with depth due to the changes in temperatures and salinity, inhibits oxygenated surface waters from mixing with oxygen depleted bottom waters, exacerbating the hypoxia. The pycnocline typically develops in LIS in late spring/early summer when rapid surface water warming exceeds the rate of warming in the bottom waters. The pycnocline generally persists into early fall when it is disrupted by strong winds associated with storms which lead to mixing or cooling air temperatures. With the dissolution of the pycnocline, hypoxic conditions are alleviated or eliminated. The smallest Delta Ts occur during the winter when the water column is well mixed. The largest Delta T's occur during the early summer. The greater the Delta T the greater is the potential for hypoxia to be more severe.

The temperature graphs on page 38 show computer interpolations along the west-east axis of LIS generated from profile data collected during two surveys by CT DEEP and IEC. During the midJuly IEC and DEEP surveys, surface water temperatures had warmed to an average of $22.5^{\circ} \mathrm{C}$ while the bottom water remained cooler around an average of $18.7^{\circ} \mathrm{C}$. This set up the largest differences in temperatures between the surface and bottom waters with Delta T's between 1.6 and $6.58^{\circ} \mathrm{C}$. The second graph shows how the water column was thermally stratified during the HYAUG16 survey when hypoxic conditions were at their worst. The temperature area maps on page 39 show how the Delta T's varied over the course of the summer sampling season. Delta T's increased from the WQAPR16 survey through the HYJUL16 survey, setting up the stratification and leading to the maximum extent of hypoxia in late August. By the September survey, Delta T's decreased to around $1.1^{\circ} \mathrm{C}$ over much of the Sound. Delta T's continued to decrease during the HYSEP 16 survey to around $0.3^{\circ} \mathrm{C}$, allowing the oxygenated surface waters to mix through to the bottom, leading to the end of the hypoxic event. The maps also show how the Delta T varies spatially. The Western Sound typically has higher Delta T's due to the limited flushing capacity, bathymetry, and geology. In the east where cooler, oxygen rich, off-shore ocean water mixes with the Sound water, Delta T's are much lower and hypoxia rarely occurs. This year the Central Sound had the highest Delta T's.

## 2016 Delta-T Maps

This table summarizes the minimum winter temperatures (January, February, and March), the maximum summer temperatures (June, July, August, and September), the maximum Delta T, and maximum hypoxic area at Station D3. Station D3 is located in the eastern-most and deepest portion of the Narrows (see map on page 1). The CT DEP 1991-1998 Data Review report (Kaputa and Olsen, 2000) found a positive correlation between the maximum Delta T observed at D3 and the maximum area of hypoxia in the same year. Delta T was not correlated to the duration of hypoxia. 2012 had the warmest minimum winter temperature, 2015 had the lowest winter temperature recorded, 2014 had the highest summer temperature, 2011 had the highest Delta T max, and 1994 had the largest area of hypoxia as indicated in bold.

| Year | Minimum Winter Temp ( ${ }^{\circ} \mathrm{C}$ ) | Maximum Summer <br> Temp ( ${ }^{\circ} \mathrm{C}$ ) | Maximum $\Delta \mathrm{T}\left({ }^{\circ} \mathrm{C}\right)$ | $\begin{gathered} \text { Maximum Area of Hypoxia } \\ \left(\mathrm{mi}^{2}\right) \\ \mathrm{DO}<3.0 \mathrm{mg} / \mathrm{L} \\ \hline \end{gathered}$ |

A compilation of CT DEEP and IEC water temperature data and Delta T calculations indicate that summer stratification in Long Island Sound was most prevalent during the middle of July and August.
Stratification broke during the middle of September, as expected, in response to cooler air temperatures and storm-induced mixing.

Time series of $\Delta \mathrm{T}$ (surface water temperature - bottom water temperature) at station D3, 1991 through 2016.
Station D3 is located in the eastern-most and the deepest portion of the Narrows. Station D3 does not experience hypoxia every year. This station is used as an example to show how stratification and the development of hypoxia in the Sound relate. Kaputa and Olsen (2000) found that there was a strong correlation between the maximum Delta T at D3 and the maximum area of hypoxia in the same year. Prior to 2004, when Station D3 became hypoxic the observed maximum Delta T was greater than $5^{\circ} \mathrm{C}$. Since 2004, this trend does not seem to hold. Over the period of record, 2011 had the highest observed Delta T at Station D3 $\left(>8^{\circ} \mathrm{C}\right)$ but the lowest dissolved oxygen concentration recorded in 2011 at D3 was $3.22 \mathrm{mg} / \mathrm{L}$. In 2015, the maximum Delta T at D3 was $6.71^{\circ} \mathrm{C}$ and the station was not hypoxic (lowest DO $3.5 \mathrm{mg} / \mathrm{L}$ ). In 2016, the maximum Delta T at D3 was $5.00^{\circ} \mathrm{C}$ and the station again was not hypoxic (lowest DO 3.84 $\mathrm{mg} / \mathrm{L}$ ).

## DEEP Salinity Data

Salinity is a measure of the concentration of dissolved salts in seawater. During the summer months, Long Island Sound waters stratify and bottom waters become cool, dense, and more saline while surface waters are warmer, less dense, and have lower salinity.

DEEP measures salinity in practical salinity units (PSU). Salinity levels across Long Island Sound vary from 23 PSU in the Western Sound at Station A4 to 33 PSU in the eastern Sound at Station M3. The Thames, Connecticut, and Housatonic rivers are the major sources of freshwater entering the Sound.

This box plot, based upon data collected during CT DEEP surveys from January 1991 September 2016, shows the median surface salinity, range, interquartile range, and outliers by station. Surface in this case refers to data collected two meters below the air/water interface. Salinity increases from west to east across the Sound.

This box plot, based upon data collected during CT DEEP surveys from January 1991-September 2016, shows the median bottom salinity, range, interquartile range, and outliers by station. Bottom in this case refers to data collected five meters above the sediment/water interface. The bottom waters are generally saltier than the surface waters.

This plot illustrates the temporal variability of the mean salinity values by station from JanuarySeptember 2016.

During the summer months, Long Island Sound waters stratify. Bottom waters become cool, dense, and more saline; surface waters are warmer, less dense, and have lower salinity. IEC salinity statistics for surface and bottom waters in the Western Sound are in the above tables. IEC measures salinity in parts per thousand (ppt). Salinity differences between surface and bottom waters are represented in the graph below.

## Water Clarity

Water clarity is measured by lowering a Secchi disk into LIS until it disappears. It is then raised until it reappears. The depth where the disk vanishes and reappears is the Secchi disk depth. The depth to disappearance is related to the transparency of the water. Water clarity in Long Island Sound follows a west to east gradient, with clarity improving as you move eastward. The graph below highlights this gradient present in Long Island Sound. In 2016, the Western-most axial station (A1 near the Whitestone Bridge) had an average summer Secchi disk depth of 1.35 meters, whereas the eastern-most axial station (M3 near Fisher's Island) had an average summer Secchi disk depth of 3.2 meters. The eastern portion of Long Island Sound is a wide and deep channel with considerable influx from the Atlantic Ocean. This exchange of waters increases water clarity in the Eastern Sound. The Western Sound is more narrow and shallow compared to the Eastern Sound and its surrounding land is densely populated and developed. This results in less of an exchange of waters and also increases the concentrations of pollutants in the water that may affect water clarity.

## pH and Ocean Acidification

Human activities have resulted in increases in atmospheric carbon dioxide $\left(\mathrm{CO}_{2}\right)$. The ocean absorbs $\mathrm{CO}_{2}$, greatly reducing greenhouse gas levels in the atmosphere and minimizing the impact on climate. When $\mathrm{CO}_{2}$ dissolves in seawater, carbonic acid is formed. This acid formation reduces the pH of seawater and reduces the availability of carbonate ions. This process is depicted in the image below from NOAA. Carbonate ions are utilized by marine organisms in shell and skeletal formation. According to the NOAA Pacific Marine Environmental Laboratory Ocean Acidification, the pH of the ocean surface waters has already decreased from an average of 8.21 Standard Units (SU) to 8.10 SU since the beginning of the industrial revolution. The Intergovernmental Panel on Climate Change predicts a decrease of an additional 0.3 SU by 2100. Additional information specific to the Northeast region is available on the North East Coastal Acidification Network's website (http://www.necan.org/).

Data from the 2016 monitoring season, depicted in the graph above, show that the pH of bottom waters is lower than pH of surface waters. Surface and bottom waters followed a similar pattern in 2016 becoming increasingly less acidic at the end of the summer, when compared to the start of summer.

In August 2010, CT DEEP upgraded its SeaCat Profilers and began collecting and reporting pH data. Year round data collected through the WQOCT16 survey are summarized below.

|  | n | Maximum Minimum | Mean | Median | SE Mean | StDev | Variance | Q1 | Q3 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Near Btm | 1394 | 8.42 | 7.00 | 7.71 | 7.73 | 0.01 | 0.27 | 0.07 | 7.50 | 7.91 |
| Bottom | 1484 | 8.76 | 6.06 | 7.83 | 7.82 | 0.01 | 0.30 | 0.09 | 7.61 | 8.06 |
| Surface | 2224 | 8.81 | 6.07 | 7.90 | 7.90 | 0.01 | 0.28 | 0.08 | 7.69 | 8.12 |

Boxplot of LIS pH
August 2010- October 2016

## Chlorophyll a

Chlorophyll is a pigment found in plants that gives them their green color. It allows plants to absorb light from the sun and convert it to chemical energy during photosynthesis. In photosynthesis, carbon dioxide and water are combined to produce sugar giving off oxygen as a byproduct. Microscopic plants, called phytoplankton, form the basis of the food web in Long Island Sound. Water temperature, nutrient concentrations, and light availability all factor into the
 amount of phytoplankton biomass found in the Sound.

The concentration of chlorophyll a is used as a measure to estimate the quantity of phytoplankton biomass suspended in the surface waters. It is most commonly used because it is easy to measure and because photosynthetic production is directly proportional to the amount of chlorophyll present.

Chlorophyll a concentrations are measured yearround by CT DEEP using the CTD fluorometer for measurement as well as through the collection of grab samples using Niskin bottles. The grab samples are brought back into the onboard laboratory, filtered, and then sent to University of Connecticut for analysis.

IEC collects grab samples during the summer months and analyzes them for chlorophyll a content in their own in-house laboratory.

The spring phytoplankton bloom occurs in Long Island Sound between February and April.
 Historically high levels of chlorophyll a in the Western Sound during this time have been linked to summertime hypoxia conditions.

This plot illustrates the temporal variability of the surface chlorophyll a values (grab samples) by station from January- May 2016. The spring bloom was captured during the CHFEB16 (2/17) survey.

Microscopic images of phytoplankton.
Judy Li, NOAA, formerly of CT DEEP

The Integration and Application Network at the University of Maryland Center for Environmental Science released the first report card for Long Island Sound to the public in 2015. Chlorophyll a thresholds were set at $5 \mathrm{ug} / \mathrm{L}$ and $20 \mathrm{ug} / \mathrm{L}$. The National Coastal Condition Report also uses these thresholds and ranks data in three categories: poor, fair, and good. Chlorophyll a concentrations less than $5 \mathrm{ug} / \mathrm{L}$ are good; concentrations between 5 and $20 \mathrm{ug} / \mathrm{L}$ are fair; and concentrations greater than $20 \mathrm{ug} / \mathrm{L}$ are poor.

This boxplot examines spring (February-April) surface chlorophyll a data from three stations (B3, D3, and F3) in the Western/central portion of LIS from 1991 to 2016. Data from February, March, and April 2012 and 2013 are not included due to a lab calibration error.

At stations D3 and F3, 90\% of the individual data are less than $20 \mathrm{ug} / \mathrm{L}$ and $75 \%$ of the data at B3 are less than $20 \mathrm{ug} / \mathrm{L}$. This would place these stations in the fair category. The average concentration at each station is less than $20 \mathrm{ug} / \mathrm{L}$ but at or above $5 \mathrm{ug} / \mathrm{L}$.

|  | n | Min | $10^{\text {th }} \%$ | $25^{\text {th }} \%$ | Median | $75^{\text {th }} \%$ | $90^{\text {th }} \%$ | Maximum | Mean | St Dev |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| B3 | 84 | 0.40 | 1.57 | 3.43 | 8.65 | 16.05 | 25.65 | 38.00 | 10.86 | 9.01 |
| D3 | 83 | 0.50 | 1.24 | 2.37 | 4.90 | 10.00 | 17.47 | 26.00 | 6.97 | 6.28 |
| F3 | 68 | 0.50 | 1.10 | 1.50 | 3.40 | 6.53 | 14.32 | 18.60 | 4.98 | 4.57 |

This boxplot examines recent data by survey.

Surface Chlorophyll a Data from Three Stations in Long Island Sound 2008-2016

## Embayment Pilot Project Sampling 2016

In 2016, CTDEEP began a pilot project to increase capacity for volunteer monitoring. The project is aimed at developing standard operating procedures for bacteria and water quality sampling in the near shore coastal waters of Connecticut.

Prior to engaging potential volunteer groups, CT DEEP conducted sampling in the Farm River in East Haven and Joshua Cove/Island Bay in Guilford. CT DEEP enlisted the Harbor Watch to sample a third embayment, Saugatuck Harbor in Westport.

Stations were sampled approximately monthly between July and September for bacteria, nutrients, and in situ parameters. Protocols were reviewed for macroalgae sampling and benthic macroinvertebrate sampling. One data loggers was deployed for a minimum of two weeks in both the Farm River and Joshua Cove to record continuous dissolved oxygen concentrations.

Additional data collection and SOP refinement will continue in 2017.

## JOB 11 PUBLIC OUTREACH

## GOAL

To increase awareness among anglers and the general public of the information products provided by this project and how this information contributes to state and federal efforts to enhance, restore and protect marine habitat and recreational fish populations.

## OBJECTIVES

1) Increase public awareness that research \& monitoring are essential to good fisheries management and the majority of marine fisheries research \& monitoring activities in Connecticut are funded through excise tax on fishing tackle and motorboat fuels

## SUMMARY

1. A total of 5,095 outdoor and environmental writers, marine anglers and boaters, marina operators, fishing tackle retailers, Fisheries Advisory Council (FAC) members, students, and members of the general public attended outreach events. The importance of research and monitoring to good fisheries management was incorporated into the programs (Table 11.2).
2. These same audiences also learned that good water quality and proper pollution prevention (nonfishing impacts) are essential to good fisheries habitat management.
3. Total attendance at five engagements with sportsmen clubs and other recreational environmental clubs was 236 (Table 11.2). The audience was encouraged to become actively involved in the fishery management process by attending public hearings and FAC meetings. Notices of public hearings were sent to hundreds of tackle shops and various media outlets including the DEEP website (www.ct.gov/deep/fishing).
4. Total attendance at one career day event at Wolcott High School was 52 (Table 11.2). The students were encouraged to become actively involved in fisheries conservation, biology and management.
5. The message that the majority of marine finfish research and monitoring are funded through Federal excise taxes on fishing and motorboat fuels was emphasized at major department outreach events (Table 11.2).

## INTRODUCTION

Public outreach was formally incorporated into this project in 1997 (segment 17). An outreach plan was developed by project staff working closely with US Fish and Wildlife Service personnel. Six target audiences were identified in priority order (Table 11.1) in the outreach plan. This report summarizes F54R outreach activities conducted from March 2016 to February 2017 (segment 35).

## RESULTS AND DISCUSSION

## Table 11.1:

## Priority Audiences for Outreach Activities

1. Outdoor/environmental writers
2. Marine anglers
3. Marine boaters and Marina operators
4. Fishing tackle retailers
5. Fisheries Advisory Council
(to CT DEEP)
6. General public

## Outdoor and Environmental Writers

DEEP press releases, project summaries, FAC quarterly reports and full annual reports were mailed and e-mailed out to several outdoor writers, members of the CT Outdoor Recreation Coalition (CORC) and Fisheries Advisory Council (FAC). Project staff were also interviewed concerning F54R activities in person, at public and regulatory hearings, and over the telephone by writers and reporters for the news media.

## Marine Anglers and Marine Boaters

Project personnel organized and assisted in DEEP, Inland Fisheries Division, and Marine Fisheries Program display at one statewide fishing/boating show. The show was sponsored by CMTA, Channel 3, Channel 30 and Connecticut Outdoor Recreation Coalition and were held in February of 2017 at the Connecticut Convention Center. These shows attracted 4,533 anglers, non-anglers, boaters, tackle retailers, legislators and general outdoor recreation enthusiasts. The theme for these show were "Enhanced Fishing Opportunities", Trophy Fish Close to Home" and "Marine Fisheries Program Angler Surveys". F54R activities were highlighted at this show in displays entitled "Trophy Fish Award Program" and "Marine Angler Surveys, (a marine fisheries cooperative management program)". Audiences learned the importance of research and monitoring which are funded through excise taxes on fishing tackle and motorboat fuels. Colorful posters and pictures, brief project specific text and taxidermy reproductions helped draw attention to marine species monitored under F54R programs and solicit questions and discussion of those programs.

Several outreach displays were developed by project staff and mounted in the lobby and hallways at the Marine Fisheries Headquarters in Ferry Point State Park. These displays highlighted unique characteristics of Long Island Sound, public access, species identification, the trophy fish award program, marine angler surveys and gave a brief description of current F54R programs designed to protect the Sound's resources. These fisheries displays can easily be viewed by anglers, boaters and their families at this popular fishing and picnic area.

The CT DEEP Marine Fisheries Trophy Fish Award Program had a record year in angler participation. 208 marine angler's participated in this outreach program, catching 26 different
species. Thirteen new state record holders, including four new species, were recognized. Marine anglers were presented with Trophy Fish Award Certificates of achievement and trophy fish lapel pin in either bronze, silver or gold color (depending on award type). Another three marine anglers were recognized as angler of the year. For a summary please see: 2016 Marine Fisheries Trophy Fish Award Program Summary

## Fishing Tackle Retailers

Fishing tackle retailers provide an important avenue for communication between the department and anglers. A complete list of fishing tackle retailers is maintained and updated yearly on the CT DEEP website. Timely DEEP press releases, species fact sheets, Connecticut angler guides and Marine Fisheries Brochure are mailed to tackle retailers to keep them informed. Correspondence between the marine fisheries office staff and retailers are ongoing.

## Fisheries Advisory Council

The Fisheries Advisory Council, which represents a cross section of Connecticut residents with interests in fisheries issues, met quarterly to discuss statewide fisheries issues. For each quarterly meeting staff produce a report of recent project activities which is distributed to FAC members and posted on our web site. Marine FAC Quarterly Report. After each meeting most Council members report Council discussions back to the fishing and environmental groups they represent. Council members also discussed monitoring and funding issues at meetings with state legislators. Many Council members visited Marine Fisheries displays at the CMTA Boating Show, Trophy Fish Award Program and other activities the Fisheries Division held during 2016-17. 'A Study of Marine Recreational Fisheries in Connecticut' was emailed to Fishery Advisory Council members to keep them informed.

## General Public

Marine Headquarters is open daily Mon-Fri. attracting thousands to the public outreach displays at the office. Display topics included all F54R projects. Activities funded under other Federal Aid in Sport Fish Restoration projects were also highlighted; including Connecticut Pumpout Stations and Waste Reception Facilities (V-4), Motorboat Access Renovation and Development (F60D), Motorboat Access Area Operation and Maintenance (F70D), and Habitat Conservation and Enhancement (F61T).

Five articles describing Sport Fish Restoration projects were published in the Department's Wildlife Magazine. The first summarized Historic Fisheries in CT -Atlantic Sturgeon. A second highlighted CT Commercial Fishing Industry - Then and Now. Other articles describe Climate Change Here and Now in Long Island Sound, Small Menhaden and Large Whales in Long Island Sound and lastly, Scoring the Health of Long Island Sound. Some of these articles were based on data gathered in Job 2.

Sport Fish Restoration projects were also highlighted at public schools and universities throughout the year. Presentations titled "Marine Fisheries Management / Sportfish Restoration and Marine Resource Management" were provided to students. These outreach events highlighted the
importance of coastal resources and all facets of marine resource protection. Approximately 52 students attended Marine Fisheries Division presentations.

Finally, project staff led numerous workshops and speaking engagements throughout the state, as well as informational tours and talks at the Marine Fisheries Office (Table 11.2). These talks and tours reached all target audiences, especially the business community, teachers and students. Audiences learned how to become active participants in the fisheries management process, through public informational hearings and FAC Meetings.

## JOB 12: MARINE FISHERIES GIS

## GOAL

To maintain a geographic information system (GIS) of Project data to support map applications and geospatial analyses, assist with planning and executing Connecticut DEEP Marine Fisheries Program (MFP) surveys that support sport fish restoration goals, help people visualize the spatial extent of MFP project sampling efforts, assist in evaluating the effects of fishing and environmental conditions on the distribution and abundance of living resources in Long Island Sound, evaluate effects of marine spatial planning projects on living marine resources and fisheries in Long Island Sound, and improve coordination with other agencies.

## OBJECTIVES

1) Provide GIS-compatible, or GIS-ready, datasets and geo-referenced layers of data collected through other Jobs of this Project that are sanctioned by the Marine Fisheries Program.
2) Provide maps and geospatial analyses of Marine Fisheries Program data or other information relevant to managing living marine resources in Long Island Sound.

## INTRODUCTION

In recent years, there has been an increased need for staff to use geospatial technology to map and analyze marine environmental or fisheries related information. Project staff have also experienced an increasing number of requests to provide geospatial data to others (intra-agency, inter-agency, NGOs, academic institutions, etc.) for use in, for example, fisheries stock assessments, habitat assessments, environmental sensitivity maps, and public outreach efforts. Therefore, in 2012, a new job was created within the project to support this need for geospatial datasets, data layers, analyses and products. This report includes results from the fifth year of the Job (2016).

## METHODS

GIS work was accomplished using ESRI ArcMap software and extensions licensed by the Connecticut DEEP. Published layers comply with Department policy pertaining to GIS data. Custom scripts were developed using well established scripting utilities (e.g. Python, HTML, CSS, JavaScript). Products designed for the Internet adhere to Agency requirements for Agency websites, pages and products. A number of the custom applications, scripts and tools created during earlier segments of the Job continue to be used as templates in subsequent years.

## RESULTS

## Saltwater Fishing Resource Maps:

Project staff used ArcGIS Online templates and widgets to create an online web application called the Saltwater Fishing Resource Map, to replace an older, outdated version on the DEEP website that was custom scripted and harder to maintain. This application was developed to help promote and protect recreational fishing opportunities in Long Island Sound. The online, interactive map
is available in two versions: a convenient format for smart phones (link to Saltwater Fishing Resource story map) that uses tabs to display different types of information on different tabs; and a version that can display all of the information at once, which is better suited for larger screens with desktop computer (link to Saltwater Fishing Resource all-in-one map) - although users can use either version from any device with access to the web. Anglers can find information that will help them plan a future fishing trip, including locations of bait and tackle shops, licensing agents, boat launches, and enhanced opportunity shore fishing sites (Job 3 in this report). Either version of the map can be accessed from the Agency website at www.ct.gov/deep/saltwaterfishing.

Figure 12.1. Saltwater Fishing Resource Maps online. Screen shot from CT DEEP web page (www.ct.gov/deep/saltwaterfishing) showing links to new versions of the Saltwater Fishing Resource Map

## Popular Places to Fish app:

GIS staff also used ArcGIS Online to create another app to gather information about the 'Popular Places to Fish' layer included in the Saltwater Fishing Resource Map. This web app was shared with agency staff to gather comments on the Recreational Fishing Activity Areas layer (the predecessor to the Popular Places to Fish layer). By using this app, fisheries staff with minimal instructions were able to modify the spatial layer directly - without the assistance of staff trained in traditional desktop GIS software. The next step in the effort to produce a comprehensive spatial layer of popular fishing areas for Connecticut anglers is to create a similarly styled app that can be shared with anglers around the state who can then use the online app to submit feedback (such as indicating additional areas or species). Ultimately, the revised Popular Places to Fish layer will be incorporated into future versions of the online Saltwater Fishing Resource Maps.

Figure 12.2. Popular Places to Fish app. A web application developed in ArcGIS Online for soliciting feedback and local knowledge from Fisheries Division staff.

## Land Cover Change Analysis:

A land cover analysis project was created to show changes in the sites used for the Alosine Seine Survey (1984-2014, Job 7 in this report). Land cover classification data were downloaded from NOAA and the Connecticut CLEAR project. For years where classification data were not available, aerial images of the survey area were compared to classification data for previous years and then manually reclassified if there were significant changes. The comparisons were able to show the increase and decrease in several different land cover classifications, including developed land, forest, wetlands, agriculture, and water.

Figure 12.3. Land Cover Change Analysis. A land cover classification raster of the Essex Seine Survey Site with aerial imagery from 1965 underneath. The current land cover classification code was compared to the actual image of the ground to determine if change occurred, and whether the classification code needed to be changed.

## NROC Northeast Ocean Data Portal:

Final versions of fish abundance and distribution data from the Long Island Sound Trawl Survey (LISTS) requested for the Northeast Regional Ocean Council's (NROC) and Northeast Regional Planning Body's (NRPB) Northeast Ocean Data Portal (NODP) were submitted and are now available for public viewing online (http://www.northeastoceandata.org/). Previously, the marine life data viewer included fish data from four other trawl surveys in the Northeast (various federal and state entities). Now that the data viewer also includes data gathered from LISTS, spatial data layers of fish abundace and distribution for LISTS can accessed from an online, interactive map viewer for the first time. Project staff submitted spatial data layers for 63 of the species catalogued by LISTS (Job 5 in this report). The viewer can display three metrics (log biomass, mean log biomass or variance of log biomass) for two time-periods (fall 1992-2014 or fall 2005-2014) for one species at a time for the survey selected. Project staff created a custom python script to generate over 370 layers of spatial data in the format requested by NROC/NRPB.

Figure 12.4. NODP map of winter flounder mean log biomass from LISTS, fall 19922014. The mean log biomass metric is site summary data. Note prevalence of relatively higher biomass along western Connecticut shoreline.

Since the NODP data viewer already contained spatial data from four other trawl surveys in the Northeast, spatial layers for LISTS had to conform as much as possible to the format of spatial
layers from the other surveys. Thus, the metrics and time-periods for LISTS data are consistent with the metrics and time-periods for the other surveys in the data viewer. However, there are some differences in the list of species available for LISTS versus the other surveys in the viewer. Since Long Island Sound (LIS) is an estuary, the spatial data layers available for LISTS in the data viewer include some inshore species not found in the spatial data layers available for the other surveys. Conversely, some of the offshore species with spatial data layers in data viewer for the other trawl survey are not available for LISTS.

Figure 12.5. NODP map of winter flounder mean log biomass from LISTS, fall 20052014. Note the relatively smaller catches along western Connecticut shoreline as compared to previous screen shot for fall, 1992-2014.

The time-period options for each survey in the NODP data viewer include the entire time-series of biomass data for the survey and the most recent ten years of data. As examples of the spatial data layers from LISTS data now available in the online NODP marine life data viewer, Figures 12.4 and 12.5 display the mean log biomass (site summary data) for winter flounder from fall LISTS for the two time-periods (1992-2014 and 2005-2014, respectively). Figures 12.6 and 12.7 display the 2005-2014 $\log$ biomass (individual tow level data) for two other species popular with recreational anglers in LIS, black sea bass and summer flounder, respectively.

Figure 12.6. NODP map of black sea bass log biomass from LISTS, fall 2005-2014.

Figure 12.7. NODP map of summer flounder log biomass from LISTS, fall 2005-2014.
