September 15, 1996

Stephen A. Harriman
Commissioner of Public Health

Commissioner:

I have the honor to submit the annual Registration Report for the year 1994, prepared by the staff of the Office of Policy, Planning, and Evaluation. At this time I wish to express my appreciation for the work performed by all the staff in preparing this report, including the Vital Records staff, who are responsible for overseeing the registration of vital events and for data collection and coding, and the staff of the Data Processing Division, Bureau of Administrative and Support Services, who are responsible for data entry and file maintenance.

Respectfully,

Marie V. Roberto, Chief
Office of Policy, Planning, and Evaluation

THEN AND NOW

Highlights of Connecticut Vital Statistics 100 Years Ago and Today^a

Statistic or event	1894	1994
Population (estimated)	815,257	3,275,251
Live births	19,493	45,795
Rate (per 1,000 population)	23.9	14.0
Deaths	13,699	29,242
Rate ^b (per 1,000 population)	16.8	8.9
Fetal deaths	852	298
Rate ^b (per 1,000 live births)	43.7	6.5
Infant deaths (<1 year old)	2,812	364
Rate (per 1,000 live births)	144.3	7.9
Marriages	5,830	22,720
Rate (per 1,000 population)	14.3	13.9
Divorces	367	11,285
Rate (per 1,000 population)	0.9	6.9
Ratio of divorces to marriages	1 to 15.8	1 to 2.0

^a The 1893 Registration Report did not distinguish between events by residence and occurrence. The 1994 figures are by residence.

^b Death rates are expressed as "crude rates."

^c Fetal deaths were called "still births" in the 1894 Registration Report.

Leading Causes of Death: 1894 and 1994

Rank	1894^a		1994	
	Cause of death	Number	Cause of death	Number
1	Consumption ^b	1,311	Diseases of the heart	9,715
2	Pneumonia	1,118	Cancer	7,128
3	Infantile diarrhoeas	943	Cerebrovascular disease	1,825

5	Accidents ^d	566	Pneumonia & influenza	1,170
6	Old age ^e	489	Unintentional injuries	1,004
7	Bronchitis	446	Diabetes mellitus	627
8	Heart disease	432	HIV infection	564
9	Cancer	416	Septicemia	389
10	Cerebral meningitis	323	Suicide	320

^a From Connecticut's *Registration Report for the Year Ending December 31, 1894*, Diagram E, Table VI, and Table XI. Deaths from other causes of interest included homicides (8), suicides (113), smallpox (13), measles (30), syphilis (16), chronic alcoholism (32), breast cancer (57), bedsores (3), kicked by cow or horse (3), run over by wagon or fire engine (4), and execution by hanging (1).

^b Pulmonary tuberculosis.

^c Cerebrovascular disease; stroke.

^d The most common causes of accidental death in 1894 were railroad injuries (132) and drowning (104).

^e "Old age" began at age 50 years.

^f COPD = Chronic obstructive pulmonary disease (chronic bronchitis, emphysema, etc.).

INTRODUCTION

The Annual Registration Report of Vital Statistics, 1994, is a statistical summary of vital events for the State of Connecticut. The State's vital statistics data base contains records pertaining to five types of events: births; deaths; fetal deaths; marriages; and divorces.

Certain qualifications must be made with regard to the data contained herein, and should be kept in mind when examining the data tables.

Completeness of Registration

The Connecticut Department of Public Health reciprocates with other states and the provinces of Canada in exchanging copies of birth and death records for non-residents. Registration of births in Connecticut is essentially 100% complete, and there is virtually no under-reporting of deaths. Because there is no interstate transfer of marriage, divorce, or fetal death records, it is not possible to determine the completeness of registration of these events to Connecticut residents.

Comparability of Cause-of-death Data

The system for classifying cause of death, the *International Classification of Diseases (ICD)*, is revised approximately every ten years to reflect changes in medical practices and new medical knowledge. As each ICD revision results in a degree of discontinuity in cause-of-death statistics, a ratio of comparability is used to adjust for classification changes in the revisions. Causes of death in 1994 were coded using the ninth revision of the ICD (known as the ICD-9), which became effective in 1979, and using the *Addendum to the International Classification of Diseases Ninth Revision* for the classification of infection with human immunodeficiency virus.

Comparison of Rates and Percentages

Rates were calculated using the equations given in Appendix I. Caution should be used in drawing conclusions based on rates or percentages that were calculated from small numbers of events. Due to the variability of these figures, the data tables do not contain rates or percentages for less than five related events. *Percentages based on birth data do not include records from which information about the characteristic of interest was missing.* The term "unknown" as used in this report includes both "missing" responses (no code entered) and responses coded as "unknown."

Reporting by Local Health Districts

Summary statistics are reported for multi-town Local Health Districts in several tables. Summations for local health districts may enable local health agencies to better understand and serve their resident populations. The composition of the respective health districts reflects membership as of **June 8, 1995** (see listing in Appendix II).

Recent Changes in Reporting of Mother's Race and Ethnicity for Births

In the 1988-1990 *Registration Reports*, the mother's race on the birth record was categorized without regard to ethnicity, such that a single birth could be counted twice in the report (e.g., as white or black *and* as Hispanic or non-Hispanic). Beginning with the 1991 *Registration Report*, the race and ethnicity classifications were modified to consist of three mutually exclusive groups: white non-Hispanic; black non-Hispanic; and Hispanic (of any race).^{*} These categories are consistent with those used by the National Center for Health Statistics, Centers for Disease Prevention and Control, thus allowing Connecticut statistics to be compared with national figures. (Please see the 1991 *Registration Report* for further explanation of this change.)

For readers who are interested in birth tabulations based on the mother's race/ethnicity classification used before 1991, comparable data are given in Appendix V. This appendix contains statistics for the eight towns with 1,000 or more births, presented in the same format as Table 4 ("Connecticut Resident Births, 1994"). These eight towns accounted for about 74% of births to Hispanic mothers, but only about 31% of all resident births in 1994.

For Further Information

Definitions of the technical terms used in this document are given in the *Glossary* at the end of this report (Appendix III). Supplemental tables containing 1994 town-specific information in the format of Table 8 (Infant Mortality) and Table 9 (Mortality, by Age) also are available. Additional 1994 vital statistics data are included in the *AVSS Advance Natality Report for Connecticut Residents, January-December 1994 Birth Data*. These publications can be obtained from the Connecticut Department of Public Health, Office of Policy, Planning, and Evaluation.

^{*} Table 2B is an exception to the general use of the composite race/ethnicity in the classification of birth data. Birth figures for this table were tabulated with separate race and ethnicity classifications (i.e., *white*, *black*, and *Hispanic*). This classification structure was retained to enable direct comparability with death data, which are given in the same table, and to make it easier for readers to compute mortality rates.

POPULATION

Age and Sex

The estimated July 1, 1994 population of Connecticut was 3,275,251 [1], which is 11,865 (0.4%) lower than the July 1, 1990 census count of 3,287,116 and 2,059 (0.06%) lower than the 1993 estimate. Of the total population, 1,587,176 were males and 1,688,075 were females. In the age groups from <1 year through 20-24 years, the number of males exceeded that of females. In all subsequent 5-year age cohorts, females exceeded males, and by ages 75-79, 80-84, and 85+ years, females outnumbered males by ratios of 3:2, 2:1, and 3:1, respectively (Fig. 1, Table 1). These ratios have been the same since 1989.

Towns

Compared to the 1990 census populations, the 1994 estimated populations were lower in 56 Connecticut towns and higher in 113 towns [2]. Seventeen towns lost 1,000 or more residents, and two towns (New Milford and Stamford) grew in population by more than 1,000. New Haven lost the most people (5,385) and Stamford gained the most (1,894). Mansfield lost the greatest percentage of residents (11.4%), and Canaan had the greatest percentage gain (15.8%). Among the five towns with populations greater than 100,000, the estimated populations of four towns decreased between 1990 and 1994 (New Haven, -4.1%; Bridgeport, -3.5%; Hartford, -3.1%; Waterbury, -1.0%); the estimated population of the fifth town, Stamford, increased by 1.8%.

Figure 1. Percent Population Pyramid of Connecticut, 1994

BIRTHS

Demographic Factors

Town of Residence

The total number of live births to Connecticut residents in 1994 was 45,795. This represents a decrease of 863 live births or 1.8% from 1993. The birth rate was 14.0 per 1,000 population, down from 14.2 in 1993 and 15.2 in 1990 (Table 2A), marking the fourth consecutive year of decline in both number and rate.

In 1994, the town-specific birth rates ranged from a high of 34.3 per 1,000 population in Canaan (the third consecutive year that this town had the highest birth rate in the state) to a low of 4.1 per thousand in North Canaan. The birth rates for 43 towns exceeded the state rate. Eight towns (Bridgeport, Danbury, Hartford, New Britain, New Haven, Norwalk, Stamford, and Waterbury) each registered more than 1,000 births during the year; these towns accounted for 30.9% of resident births but only 25.4% of the population in the state (Table 2A). Except for Norwalk, however, both the numbers and rates of births in these towns in 1994 were lower than their 1993 values.

Mother's Race and Ethnicity

Of the 45,795 resident live births, 30,901 were to white non-Hispanic mothers and 4,767 were to black non-Hispanic mothers, representing 67.5% and 10.4% of the total resident births, respectively. There were 5,296 births to mothers of Hispanic origin, 11.6% of the total number of resident births (Table 3). Race was unknown for 1,185 births (2.6%), and ethnicity was unknown for 3,442 births (7.5%) (Table 2B).

Sex

Of the total live births, 23,365 (51.0%) were male and 22,430 (49.0%) were female (Table 3).

Place of Delivery

All but 225 (0.5%) of the total resident births occurred in hospitals (Table 3). There were 201 home births, up from 172 in 1993. Home births accounted for nine out of ten non-hospital deliveries (Table 3).

Live Birth Order and Plurality

Of babies delivered in 1994, 38.9% were first-born; 30.4% were second-born, and 20.6% were third-born or more. In the remaining 10.1% of deliveries, the birth order was not known. Of the total births, 1,333 (2.9%) were multiple births (Table 3).

Mother's Presumptive Marital Status

Connecticut law prohibits inclusion of the mother's marital status on birth records; consequently, marital status is inferred by matching the mother's, father's, and child's surnames according to certain criteria [3]. This method of assessing marital status is probably of limited validity, because it assumes that married women who do not adopt their husbands' surnames are unmarried. Following these criteria, in 1994, 13,901 resident births, or three out of ten, were presumptively to unmarried mothers (Table 3).

Mother's Age

Although the total number of live births was lower in 1994 than in 1993, there were increases in the numbers of births to women aged 15 to 18 and in all age groups over 34 years. From 1993 to 1994, the greatest percent increase in births (25.3%) occurred among 15 year olds, and the greatest decrease (7.6%) occurred in the 20-24-year age cohort. Mothers in the age range 20 to 34 accounted for 76.0% of all 1994 births, down from 77.4% in 1993 (Table 3).

For the second consecutive year, more births (14,316 or 31.3%) occurred to women aged 30-34 than to women in any other 5-year age cohort. This is noteworthy because, for the prior 47 years and possibly longer, women in the age groups 20-24 or 25-29 had accounted for the greatest numbers and proportions of births to Connecticut residents [4]. An additional 15.6% (7,131 births) were to women aged 35+ years, up from 14.5% (6,766) in 1993; of these, 1,042 (135 more than in 1993) were to women aged 40 and over.

Teenagers accounted for 3,873 births or 8.5% of resident births, up from 3,757 (8.0%) in 1993. Of total births, 3.8% (1,751) were to females under age 18; these included 102 births to mothers less than 15 years old (Table 3). This was the highest percentage of births to mothers under age 18 since 1982.

Nearly eight out of ten (78.2%) mothers aged 35+ years were white non-Hispanic, whereas the majority (58.1%) of teenage mothers were black non-Hispanic (24.2%) or Hispanic (33.9%). Of total births in each racial/ethnic subgroup, 75 births (4.3%) to white non-Hispanics, 107 births (19.7%) to black non-Hispanics, and 167 births (24.8%) to Hispanics were to females under the age of 16 (Table 3).

Low Birthweight

Overall, 3,140 or 6.9% of all births in 1994 were of low birthweight (<2,500 grams) (Table 4); this percentage has been the same since 1991. The risk of low birthweight delivery was not distributed evenly across all communities (Table 4) or risk groups (Table 3). Substantial variation in low birthweight occurred within categories defined by mother's race/ethnicity, sex of baby, plurality of births, mother's presumptive marital status, mother's education, mother's age, initiation and adequacy of prenatal care, and town of residence, as noted below.

Race/Ethnicity

The percentages of low-birthweight deliveries in 1994 to white non-Hispanic, black non-Hispanic, and Hispanic residents were 5.5%, 12.6% and 9.0%, respectively (Tables 3 and 4). These represented slight increases from the 1993 rates for black non-Hispanics and Hispanics (12.5% and 8.8%, respectively) and no change from the 1993 rate for white non-Hispanics. Still, black non-Hispanic mothers and Hispanic mothers had 2.3 and 1.6 times the risk of white non-Hispanic mothers, respectively, to deliver low-birthweight babies, and 4.6 and 1.9 times the risk, respectively, for very low birthweight delivery (<1,500 grams), respectively [5].

Sex

As in previous years, female babies were somewhat more likely than male babies to have low birthweight (7.6% vs. 6.3%). This was true regardless of the mother's race or ethnicity (Table 3).

Plurality

Nearly half (48.4%) of all multiple births were low birthweight, compared to only 5.7% of singleton births (Table 3).

Mother's Presumptive Marital Status

Presumptively unmarried mothers [3] were twice as likely as married mothers to deliver low birthweight babies (10.5% and 5.3%, respectively).

Mother's Education

Mothers with 12 years or less of education had the highest percentage (8.1%) of low-birthweight births (Table 3). Overall, and for each racial/ethnic subgroup, mothers who were college educated and those with post-college education had lower percentages of low-birthweight deliveries (5.8% and 5.2% overall, respectively).

Mother's Age

In general, higher percentages of low birthweight were found among mothers under age 25 and over age 39. Mothers less than 15 years old had the highest level of low birthweight deliveries, 15.3%, whereas women aged 25 to 29 had the lowest level, 5.8%. Interestingly, the 17- and 19-year age groups had slightly lower percentages of low birthweight than the 20-24-year group (8.0, 8.3, and 8.8%, respectively). Among black non-Hispanic mothers, percentages of low-birthweight deliveries were consistently high and reached double digits in all age groups except 17 and 19 years (Table 3) [5].

Initiation of Prenatal Care

The trimester of pregnancy in which women begin prenatal care is a strong indicator of risk of low birthweight. Generally, the later the prenatal care begins, the greater the likelihood of low birthweight deliveries. In 1994, women who received no prenatal care were 4.4 times more likely than women who began care during the first trimester of pregnancy to deliver low-birthweight babies (28.0% and 6.4%, respectively) (Table 3).

Adequacy of Prenatal Care

Adequacy of prenatal care, as defined by a modified Kessner Index (see Appendix III), is a measure involving the timing of the first prenatal visit, the total number of prenatal visits and the length of gestation. The highest risk subgroup, "inadequate care," had more than three times the risk of low-birthweight deliveries as the lowest risk subgroup, "adequate care" (18.0% and 5.7%, respectively) (Table 3).

Town of Residence

As in previous years, percent low birthweight varied greatly across communities within Connecticut (Table 4). In the eight towns with 1,000 or more births, there was a two-fold difference between the towns with the lowest and highest percentages (Norwalk, 6.5% and Hartford, 12.7%). The percentages of low birthweight deliveries in the remaining towns in this group all exceeded the state rate of 6.9%. They were: New Haven, 10.0%; Bridgeport, 9.5%; Waterbury, 8.7%; Stamford, 8.2%; Danbury, 7.7%; and New Britain, 7.7%. These towns accounted for 1,309 low-birthweight deliveries, or 41.7% of low birthweight births to Connecticut mothers, but only 30.9% of total resident births.

Premature Births

In 1994, 9.0% of all resident births were premature (<37 weeks of gestation), down from 9.5% in 1993 (Table 3) [6]. Substantial variation occurred within the categories defined by mother's race/ethnicity, place of delivery, plurality, mother's presumptive marital status, mother's education,

mother's age, initiation of prenatal care, and adequacy of prenatal care. These differences are similar to those noted for low-birthweight deliveries. There was no variation, however, by infant's sex. Overall, 4.2% (1,908) of the birth records were missing information on prematurity; this reflects significant improvement from the reporting of prematurity in 1990, when 10.8% of records had missing information.

Race/Ethnicity

The percentages of premature births were: white non-Hispanic, 7.6%; black non-Hispanic, 15.2%; and Hispanic, 11.7% (Table 3). Relative to white non-Hispanics, the risk of preterm delivery was thus twice as great for black non-Hispanics [5] and 1.5 times greater for Hispanics.

Place of Delivery

Premature babies were more likely to be delivered in hospitals than at home (9.0% and 7.8% premature births, respectively) (Table 3).

Plurality

Premature birth occurred more than six times more often with multiple births (48.5%) than with singleton births (7.9%) (Table 3).

Mother's Presumptive Marital Status

Premature delivery occurred 63% more often among presumptively unmarried women [3] than among married women (12.4% and 7.6%, respectively).

Mother's Education

Premature delivery among mothers who had 12 years or less of education occurred 29% more frequently than among college-educated mothers and 41% more often than among post-college-educated mothers (10.3%, 8.0%, and 7.3% prematurity, respectively). At each education level, the percent of preterm delivery was higher for black non-Hispanics than for any other racial/ethnic subgroup (Table 3).

Mother's Age

In all age groups except 25-29 and 30-34 years, the levels of premature delivery exceeded the state level of 9.0% (Table 3). Percentages of prematurity were highest among mothers in the five groups under age 19 (range, 11.9-17.8%) and in the 40-44 year group (12.3%). Relative to the age group with the lowest rate of premature deliveries (ages 25-29, 7.9%), the figures for women <19 years old were 1.5 to 2.3 times higher. The rates of premature births were consistently high among black, non-Hispanics, regardless of age (low, 13.3%, age 19; high, 27.1%, ages 40-44) [5].

Initiation of Prenatal Care

Compared to women who began prenatal care in the first trimester of gestation, the risk of premature delivery was *three times greater* for those who received no prenatal care and 1.7 times greater for those who began prenatal care during the last trimester (8.5%, 24.8%, and 14.3% prematurity, respectively). There were 2,947 birth records (6.4% of total) for which trimester of initiation of prenatal care was not known (Table 3). (See *Glossary* for definition of "trimester of pregnancy.")

Adequacy of Prenatal Care

Premature delivery varied with adequacy of prenatal care, as defined by a modified Kessner Index (Appendix III). Women who received inadequate care were 2.7 times more likely to deliver prematurely than were those women who received adequate care (21.6% and 8.0%, respectively) (Table 3).

Births to Teenage Mothers

In 1994, 3,873 or 8.5% of all live resident births were to teenage mothers, i.e., <20 years old, marking the first increase in number of teen births since 1989 (Table 4). Between 1989 and 1993, teen births had dropped 11% from 4,214 to 3,757. Also, 1994 was the second consecutive year of increase in percent of births to teenage mothers (1992, 8.0%; 1993, 8.1%). Teen mothers accounted for 4.3% of all white non-Hispanic births, 19.7% of all black non-Hispanic births, and 24.8% of all births to Hispanic women, representing increases from 1993 levels for all three groups.

Of the eight towns with 1,000 or more births, five exceeded the state rate of 8.5% births to teens. They were: Hartford, 28.3% (the highest in the state); Bridgeport, 18.8%; New Haven, 18.7%; New Britain, 16.2%; and Waterbury, 13.9%. These five towns accounted for more than half (50.9%) of all births to teenage mothers, but only about one-fifth (21.4%) of all births in the state (Table 4). Each of the remaining three towns with 1,000 or more births, Danbury, Norwalk, and Stamford, was below the state rate, with 8.4%, 5.9%, and 5.2%, respectively (Table 4).

Prenatal Care

Initiation of Prenatal Care

The rate of births to Connecticut mothers who received late prenatal care (that which began after the 13th week of pregnancy) or no prenatal care was 11.5%, down a full percentage point from the 1993 rate. The rates for black non-Hispanic and Hispanic mothers were both about three times that for white non-Hispanics, that is, 23.4%, 22.5%, and 7.8% respectively. The rates for all three groups decreased with respect to the 1993 figures.

Of the eight towns with 1,000 or more births, six exceeded the state percentage of women who had late or no prenatal care. They were: Waterbury, 30.0%; New Haven, 21.9%; Norwalk, 19.9%; Stamford, 18.6%; Bridgeport, 16.8%; and Hartford, 16.3% (Table 4). Except for Bridgeport, which rose by 4.2 percentage points, the 1994 rates were all substantially lower than in 1993.

These six towns accounted for 43.7% of births to women who received late or no prenatal care but only 26.1% of total resident births. Of the remaining two towns with 1,000 or more births, Danbury (6.5%) was well below the state value, and New Britain (10.8%) was slightly lower. Overall, 6.4% of birth records were missing information on entry into prenatal care (Table 3).

Adequacy of Prenatal Care

Overall, 15.7% of resident births in 1994 were to mothers who received non-adequate prenatal care (i.e., intermediate or inadequate) (Table 4); this was a marked improvement from 19.0% in 1993. Although rates were lower for women in all race/ethnicity subgroups, both black non-Hispanic and Hispanic women still were nearly three times as likely as white non-Hispanics to receive non-adequate care (30.7%, 31.0%, and 10.9%, respectively). (See Appendix III, *Glossary* for definition of "adequacy of prenatal care.")

Of the eight towns with 1,000 or more births, one town, Danbury, was below the state percentage for non-adequate care (7.9%, down from 11.1% in 1993), and the other seven towns had percentages greater than the state's. Except for Hartford (23.9%, up from 23.5% in 1993), the percent non-adequate care for these seven towns was lower than in 1993. The most dramatic improvement occurred in Bridgeport (28.6%, down from 60.8%). Rates for the other towns were: Waterbury, 33.3% (down from 39.2%); New Haven, 29.2% (down from 34.1%); Stamford, 21.7% (down from 25.7%); Norwalk, 21.7% (down from 24.5%); and New Britain, 20.5% (down from 21.9%) (Table 4). The eight towns with 1,000+ births accounted for 44.4% of births to Connecticut women who received non-adequate prenatal care but only 30.9% of total resident births. Overall, 11.3% of the birth records were missing information needed to determine adequacy of prenatal care (Table 3).

FETAL DEATHS

Fetal deaths (stillbirths) are deaths to fetuses after 20 or more weeks of gestation. There were 298 resident fetal deaths in 1994, for a statewide rate of 6.5 per 1,000 live births (Table 2A), a 12.1% increase from the 1993 rate of 5.8 per 1,000. There were more male than female fetal deaths (51.3% and 48.0%, respectively), and two deaths (0.7%) of fetuses of unknown sex (Table 5). Eleven percent of the fetal deaths were of multiple plurality (Table 5); this is nearly four times the proportion of live births of multiple plurality (2.9%) (Table 3). The distribution of fetal deaths by mother's age was about the same as that of live births by mother's age; that is, no particular age group was more likely to produce stillbirths than live births.

Town of Residence

Among the eight towns with 1,000 or more births, seven had higher fetal death rates than the 1994 state rate. They were: New Haven, 12.1 per 1,000 (up from 10.5 in 1993); Hartford, 10.9 per 1,000 (up from 7.2); Waterbury, 9.9 per 1,000 (up from 9.5); Danbury, 8.9 per 1,000 (up from 4.4); New Britain, 8.6 per 1,000 (1993 rate could not be calculated because there were less than 5 deaths); Bridgeport, 8.3 per 1,000 (down from 11.0); and Stamford, 6.9 per 1,000 (down from 11.1) (Table 2A). The eighth town, Norwalk, had a fetal death rate of 5.3 per 1,000 (up from 4.6 in 1993). These eight towns accounted for 40.9% of total fetal deaths but only 30.9% of resident live births in the state.

Low Birthweight and Premature Delivery

Eight of every ten resident fetal deaths (79.5%) were of low birthweight (<2,500 grams), and 65.9% were of very low birthweight (<1,500 grams) (Table 5). The percent fetal deaths with low birthweight was uniformly high for mothers of white race, black race, and Hispanic ethnicity. Overall, 80.2% of the resident fetal deaths were delivered prematurely (<37 weeks of gestation) (Table 5).

Leading Causes of Fetal Death

The three leading causes of fetal death for all races in 1994 were: 1) "other and ill-defined conditions originating in the perinatal period" (92 deaths); 2) "fetus affected by complications of placenta, cord, and membranes" (73 deaths); and 3) "disorders relating to short gestation and unspecified low birthweight" (40 deaths) (Table 6). These categories are based on the standard groupings used by the National Center for Health Statistics [8]. There was racial and ethnic variation among the first and second leading causes of death, whereas the third leading cause of death was the same regardless of race or Hispanic ethnicity (Table 6).

INFANT DEATHS

In 1994 there were 364 resident infant deaths. The overall infant mortality rate was 7.9 deaths per 1,000 live births--the highest rate since 1990--and was 11.3% higher than the 1993 rate of 7.1 per 1,000. The neonatal mortality rate, based on 265 deaths to infants less than 28 days old, was 5.8 deaths per 1,000 live births; this was up 16% from the 1993 rate, and was the highest rate since 1989. About three out of four infant deaths occurred during the neonatal period. The postneonatal mortality rate (based on 99 deaths to infants 28 days to 364 days old) was 2.2 deaths per 1,000 live births, up 4.8% from the 1993 rate (Table 2A).

Infant's Race

Infant mortality rates were calculated using two race-specific components: births, which reflect the race of the *mother*; and deaths, which reflect the race of the *infant*. In 1994, infant mortality rates again varied conspicuously by race, with disproportionate deaths to black infants; blacks accounted for 28.9% of resident infant deaths, but only 12.1% of total resident births. There were 250 deaths to infants of white race, for a rate of 6.7 per 1,000 live births (up 13.6% from the 1993 rate of 5.9), 105 deaths to infants of black race, for a rate of 18.9 per 1,000 (up 17.4% from the 1993 rate of 16.1), and 9 deaths to infants of other races. There also were 51 deaths to infants of Hispanic ethnicity; this mortality rate was not calculated, however, because of considerable under-reporting of Hispanic ethnicity on infant death certificates [7]. Ethnicity was unknown for 19 infant deaths (Table 2B).

Town of Residence

In 1994, four towns reported ten or more resident infant deaths. They were: Hartford, 50 (19.5 deaths per 1,000 live births); Bridgeport, 36 (15.0/1,000); New Haven, 27 (13.6/1,000); and Waterbury, 15 (8.3/1,000). Together, these towns accounted for 35.2% of infant deaths but only 19.2% of resident births.

Leading Causes of Infant Death

Since 1991, the classifications for leading cause of infant death in Connecticut have followed the standard groupings used by the National Center for Health Statistics [8]. Based on these groupings, the top three leading causes of infant death among all Connecticut residents were: 1) "congenital anomalies;" 2) "disorders relating to short gestation and unspecified low birthweight;" and 3) "sudden infant death syndrome" (Table 8). The rankings of leading causes varied, however, by racial and ethnic subgroup, as shown below.

Rank order of leading causes of infant death by infant's race and Hispanic ethnicity, Connecticut, 1994.

Cause of Death	Race			
	All	White	Black	Hispanic
Congenital anomalies	1	1	2	2
Disorders relating to short gestation or unspecified low birthweight	2	3	1	3
Sudden infant death syndrome	3	2	3	1

DEATHS (All Ages)

The total number of deaths among Connecticut residents in 1994 was 29,242, for a crude death rate of 8.9 deaths per 1,000 population (Table 2A). Of the total number of resident deaths, 14,345 (49.1%) were males and 14,897 (50.9%) were females; 92.0% were of white race, 7.7% were of black race, and 2.7% were of Hispanic ethnicity (Table 9). Six decedents were of unknown race, and 986 were of unknown ethnicity (Table 2B); these figures represent significant improvements in death record completeness compared to 1993, when there were 48 and 1,473 unknowns, respectively.

All Causes of Death

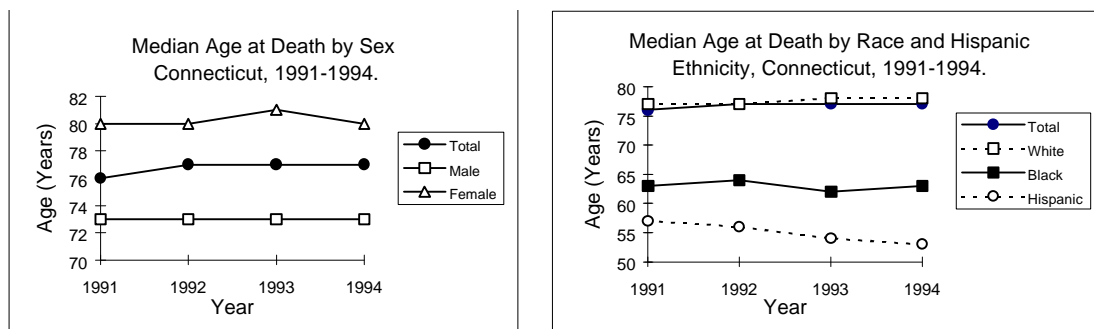

Town of Residence

Four towns reported 1,000 or more deaths in 1994 (Table 2A). Each had a crude death rate above the state rate: Waterbury, 10.6 per 1,000; New Haven, 10.1 per 1,000; Hartford, 10.1 per 1,000; and Bridgeport, 10.0 per 1,000. Among Connecticut's 169 towns, Burlington had the lowest crude death rate (3.2 per 1,000) and Southbury had the highest (17.0 per 1,000).

Median Age at Death

Total resident deaths were determined by age of decedent for each sex, race, and ethnicity (Table 9). There were 16,255 deaths of persons aged 75 years and over, representing 55.6% of total resident deaths in 1994. The median age at death (see Appendix III, *Glossary*, for definition) was 77 years for both sexes combined, 73 years for males, and 80 years for females [9]. With respect to the 1993 figures, the 1994 median age at death was unchanged for males and for both sexes combined, whereas it was 1 year lower than in 1993 for females (see figures below). Variation in median age at death was greater when broken down by race and ethnicity: whites, 78 years (unchanged from 1993); blacks, 63 years (up 1 year from 1993); Hispanics, 53 years (down 1 year from 1993) [9].

Median age at death by sex and race/ethnicity, Connecticut, 1991-1994.

Leading Causes of Death

The five leading causes of death in 1994 for persons of all ages and independently within each age and sex group are shown in rank order in Table 10. By proportional share of total deaths, they were: 1) "diseases of the heart;" 2) "malignant neoplasms;" 3) "cerebrovascular disease;" 4) "chronic obstructive pulmonary disease" (COPD); and 5) "pneumonia and influenza." These leading causes have been the same since 1989, with some alternation in rank order between COPD and pneumonia and influenza.

Age and Sex

Total deaths by age and the leading cause of death by age and sex are summarized in the table below.

First-ranked leading cause of death by age and sex, Connecticut, 1994.

Age	Sex			Total Deaths by Age ^b	
	Both	Male	Female	No.	%
<1	Congenital anomalies	Congenital anomalies	Congenital anomalies	364	1.2
1-4	Unintentional injuries	Unintentional injuries	Unintentional injuries	54	0.2
5-9	Unintentional injuries	Unintentional injuries	^a	33	0.1
10-14	Unintentional injuries	Unintentional injuries	Unintentional injuries	61	0.2
15-19	Unintentional injuries	Unintentional injuries	Unintentional injuries	143	0.5
20-24	Unintentional injuries	Unintentional injuries	Unintentional injuries	195	0.7
25-34	Unintentional injuries	Unintentional injuries	HIV infection	682	2.3
35-44	HIV infection	HIV infection	Malignant neoplasms	1,182	4.0
45-54	Malignant neoplasms	Diseases of the heart	Malignant neoplasms	1,660	5.7
55-64	Malignant neoplasms	Malignant neoplasms	Malignant neoplasms	2,608	8.9
65-74	Malignant neoplasms	Malignant neoplasms	Malignant neoplasms	6,004	20.5
75-84	Diseases of the heart	Diseases of the heart	Diseases of the heart	8,538	29.2
85+	Diseases of the heart	Diseases of the heart	Diseases of the heart	7,717	26.4
All ages	Diseases of the heart	Diseases of the heart	Diseases of the heart	29,242 ^b	99.9

^a Malignant neoplasms, septicemia, and all other infections and parasitic diseases each caused two deaths in this group.

^b Total includes one death of unknown age.

^c Percents do not total to 100.0% because of rounding.

Age <1 Year. (See INFANT DEATHS, p. 10.)

Ages 1-34 Years. The age groups within the 1-34 year interval accounted for 1,168 deaths, or 4.0% of total deaths. "Unintentional injuries" was the leading cause of death for males and for both sexes combined within the six age groups after infancy (1-4 through 25-34 years), and for females in the age cohorts from 1-4 and 10-24 years. Within this category, "motor vehicle accidents" claimed the most lives.

"Malignant neoplasms" became the second leading cause of death for males and both sexes combined in the age groups from 5 to 14 years and females aged 20-24 years, overtaking "homicide and legal intervention." "Homicide and legal intervention," however, remained the second leading cause of death of males and both sexes combined, ages 15 to 24 years, and

replaced "malignant neoplasms" as the second leading cause of death for 15-19 year old females. In the age group 25-34, "HIV infection" was again the leading cause of death of females and the second leading cause of death of males and both sexes combined.

Ages 35-44 Years. The 35-44 year age interval accounted for 1,182 deaths, or 4.0% of total deaths. "HIV infection" remained the leading cause of death in this age cohort for males and both sexes combined, and was again the second leading cause of death of females. "Malignant neoplasms" was the leading cause of death of females aged 35-44 and the second leading cause of death for both sexes combined, whereas "unintentional injuries" remained the second leading cause of death of males. "Lung cancer" caused the most cancer deaths of males and both sexes combined, and "female breast cancer" took the most lives of women in this group.

Ages 45-74 Years. The next three consecutive age groups, 45-54, 55-64, and 65-74, accounted for 10,272 deaths, or 35.1% of total deaths in 1994. "Diseases of the heart" was the leading cause of death of males aged 45-54 for the second consecutive year, while "malignant neoplasms" overtook heart disease to become the leading cause of death of men between the ages of 55 and 74. "Malignant neoplasms" also remained the leading cause of death for females and both sexes combined. "Lung cancer" was the most frequent cause of cancer deaths in males and both sexes combined in the 45-to-74-year age cohorts and in females aged 55-74. "Female breast cancer," however, still caused the most cancer deaths in women aged 45-54.

"Diseases of the heart" was the second leading cause of death for all groups in this age bracket except males aged 45-54, for which the second leading cause was "malignant neoplasms." In 1994, "HIV infection" replaced "unintentional injuries" as the third leading cause of death of both sexes combined in the 45-54 year group.

Ages 75+ Years. The two age groups above 75 years accounted for 16,255 deaths, or 55.6% of total deaths in 1994. Overall and for each sex cohort in the age groups 75-84 and 85+ years, the leading cause of death was "diseases of the heart." "Ischemic heart disease" was the largest component within this category, accounting for six of every ten deaths. The second leading cause of death in these age groups was "malignant neoplasms." Among cancer deaths, "lung cancer" took the most lives of all decedents between the ages of 75 and 84 and of males aged 85+. "Colorectal cancer" was the leading cause of cancer deaths in the age/sex groups 85+/female and 85+/both sexes.

Selected Causes of Death

It is also important to monitor mortality patterns among major causes of death other than the top five. Resident deaths from different causes by sex, age, and race/ethnicity are given in Table 9. The 15 selected causes of death discussed here comprise the top 14 leading causes [8] plus "motor vehicle accidents," a subgroup of "unintentional injuries" that is particularly important to public health. These 15 categories also are the focus of the discussion of age-adjusted mortality rates (see next section and Appendix IV).

To provide a general indication of the population subgroups at elevated risk, the distributions of deaths by sex and age were examined and are discussed below.

Sex

Although total deaths of males and females were about equal, the numbers of male and female deaths were disproportionate for certain causes. As shown in the table below, male and female counts differed by a factor of 1.5 or more for 7 of the 15 selected causes of death.

**Ratios of deaths for selected causes of death^a, Connecticut, 1994.
(M/F = male to female ratio; F/M = female to male ratio.)**

Cause of death	Ratio (M/F)	Ratio (F/M)
ALL CAUSES	1.0	
Human immunodeficiency virus (HIV) infection	3.5	
Suicide	3.5	
Homicide and legal intervention	3.1	
Unintentional injuries	1.9	
Chronic liver disease and cirrhosis	1.7	
Atherosclerosis		2.3
Cerebrovascular disease		1.6

^a See list of selected causes of death in Appendix IV.

Variation also existed between sexes in different racial and ethnic groups. For "all causes" of death, deaths of white females and white males were within 7% of one another, whereas deaths of males exceeded deaths of females by 30% for blacks and 74% for Hispanics.

Age

The distributions of deaths of males and females varied with age for each cause of death (Table 9). Total deaths from "all causes" increased rapidly after age 65; 50% of these deaths occurred at ages 65 to 84 years and 25% after age 84, whereas only about 25% of deaths occurred below age 65. For six of the 15 selected causes of death, however, the age profiles differed markedly from those for "all causes."

Deaths from "human immunodeficiency virus infection" peaked at ages 35-39 years, and then declined in later years. While the HIV age profile was the same for males and females, the age profiles for the five other selected causes also differed by sex. The number of deaths peaked and then fell off for "chronic liver disease and cirrhosis" (peak years: males 50-54; females 70-74), "suicide and self-inflicted injury" (peak years: males 30-34; females 45-49), and "homicide and legal intervention" (peak years: males 20-24; females 30-34). In contrast, the number of deaths due to "unintentional injuries" was highest in the oldest age group for females (peak years: males 40-44; females 85+). Finally, the numbers of deaths of males and females from "motor vehicle accidents" peaked at early ages (peak years: males 20-24; females 15-19), but females also had a secondary elevation in later years, with a peak in the age group 75-79 years.

AGE-ADJUSTED MORTALITY RATES 1970, 1980, & 1984-1994

Trends in age-adjusted mortality rates (AAMRs) for 1970 and 1980 through 1994 for all causes and for 15 selected causes of death are shown in Appendix IV and Figures 2-6. Age-adjusted rates, rather than crude rates, were used so that populations with different age distributions could be compared. (See Appendix III, *Glossary*, for definitions of death rates.) Mortality rates were adjusted to the 1970 U.S. standard million population, using the direct method [10].

All Causes of Death

The mortality rate from "all causes" increased to 622.0 deaths per 100,000 population in 1994. This was the second consecutive year that the rate increased, after more than two decades of continuous decline to a low of 612.3 deaths per 100,000 in 1992 (Fig. 3).

Human Immunodeficiency Virus Infection

Mortality rates for "human immunodeficiency virus (HIV) infection" were not available until 1987, the first year that specific codes were assigned to classify "HIV infection" as a cause of death. Between 1987 and 1994, the AAMRs for "HIV infection" increased 255%, from 3.8 to 13.5 deaths per 100,000 population, surpassing the rates for deaths from "suicide and self-inflicted injuries," "motor vehicle accidents," "septicemia," "chronic liver disease and cirrhosis," "homicide and legal intervention," "nephritis and nephrotic disease," and "atherosclerosis." In 1994, the AAMR for "HIV infection" increased by 8.0%, which was the largest percent increase that year among the selected causes of death listed in Appendix IV.

Other Selected Causes of Death

AAMRs That Increased in 1994

The AAMR for "unintentional injuries" increased for the third consecutive year to 25.6 deaths per 100,000 population (an increase of 4.5% from 1993 and 14.3% from 1991). The rate for "diabetes mellitus" also increased for the third year in a row to 13.6 per 100,000, its highest level since 1980 (a 7.1% increase from 1993 and a 22.5% increase from 1991). Other rates that increased from 1993 to 1994 were: "suicide and self-inflicted injury," up 7.4%; "chronic obstructive pulmonary disease," up 6.6%; "atherosclerosis," up 6.5%; "chronic liver disease and cirrhosis," up 4.1%; "nephritis and nephrotic disease," up 1.6%. The AAMR for "malignant neoplasms" increased to 163.9 per 100,000, up 1.5% from its 23-year low of 161.5 in 1993; however, there has been only a 10% difference between the high and low since 1980.

AAMRs That Decreased in 1994

In 1994 the AAMR for "diseases of the heart" fell to a 24-year low of 192.5 per 100,000, down 2.4% from the 1993 rate. Other causes of death for which AAMRs decreased in 1994 were: "motor vehicle accidents," down 6.5%; "pneumonia and influenza," down 2.8%; and "septicemia," down 6.0% to 7.8 per 100,000, its lowest level since 1985.

AAMRs That Did not Change in 1994

The age-adjusted mortality rates for "cerebrovascular disease" (34.5 per 100,000) and "homicide and legal intervention" (6.8 per 100,000) were the same as their respective 1993 rates. Homicides remained at an all-time high.

MARRIAGES

Marriage Rate

In 1994, there were 22,720 marriages in Connecticut (Table 11). This was 94 (0.4%) fewer than in 1993, and was the lowest number registered since 1977. The number of marriages in Connecticut has been declining since it reached an all-time high of 27,892 in 1988. The 1994 total represents a marriage rate of 13.9 persons per 1,000 population, the same as in 1993.

Number of Prior Marriages and Prior Marital Status

In 16,241 marriages (71.5%), the bride had never been married before, and in 16,137 (71.0%), the groom was marrying for the first time (Table 11). Sixty percent or 13,609 of all the marriages were between individuals marrying for the first time, and 10.3% or 2,341 were between individuals marrying for a second time. Twenty-four brides and 26 grooms had previously been married four or more times. Twenty-five percent of the brides and 26% of the grooms had been divorced previously, and 2% of brides and grooms were widowed (Table 12).

Town of Registration

Six towns each registered more than 500 marriages in 1994. They were Hartford (1,128), New Haven (889), Bridgeport (827), Stamford (759), Waterbury (673), and Greenwich (531) (Table 2A). The most marriages were registered in Hartford, and the fewest (4) in Union, which also has the smallest population in Connecticut. For the first time since 1986, there were marriages (18) registered in the town of Middlefield.

DIVORCES

Divorce Rate

There were 11,285 divorces in Connecticut in 1994, or one for every two marriages, yielding a divorce rate of 6.9 persons per 1,000 population (Table 13A). This was slightly lower than the 1993 rate of 7.0 per 1,000.

Grantees and Minor Children

Of divorces for which the grantee was known, those granted to the wife outnumbered those granted to the husband by a ratio of 2 to 1 (Table 13B). Of divorces for which number of children affected was known, 84.4% occurred in families with children under the age of 18, and at least 9,745 minor children were affected (Table 14) [11].

Duration of Marriages

The median duration of marriages has been estimated for Connecticut residents since 1978. It is calculated by subtracting the year the marriage was contracted from the year it was dissolved. In 1994, the median duration of marriages increased for the first time since 1986, from 8 years to 9 years. The greatest number of divorces (868) occurred after marriages of 4 years duration. Thirty percent of the divorces during 1994 occurred within the first 5 years of marriage, and 58% occurred within 10 years. After 20 or more years of marriage, 1,914 marriages (17.0%) were dissolved, and 17 dissolutions occurred after 50 or more years of marriage (Table 15). More husbands (499) were divorced at age 35, and more wives (507) at age 30, than at any other ages [12].

NOTES

- [1] *Estimated Populations in Connecticut as of July 1, 1994*. Hartford: Connecticut Department of Public Health, Office of Policy, Planning & Evaluation, September, 1995.
- [2] *Results of the July 1, 1994 Population Estimates for Connecticut*. Hartford: Connecticut Department of Public Health, Office of Policy, Planning and Evaluation, October 27, 1995.
- [3] According to the *Connecticut General Statutes*, "No certificate of birth shall contain any specific statement that the child was born in or out of wedlock or reference to illegitimacy of the child or to the marital status of the mother." The proxy "marital status" indicator, presumptive marital status, is based on the matching of surnames, with the classification "married" assigned under the following three conditions: i) if there is an exact match between the mother's and father's surnames; ii) if the father's and child's surnames match exactly, but the mother's name is missing; iii) if the child's surname is a hyphenated combination of the mother's and father's surnames (either entire surnames or portions of the parents' hyphenated surnames). This method of assessing marital status is probably of limited validity, because it assumes that married women who do not adopt their husbands' surnames are unmarried.
- [4] In Connecticut, live births were not tabulated annually by age of mother until 1947, when only 21.3% of total live births were to women aged 30-34. Between 1947 and 1992, the greatest proportions of live births occurred to women aged 20-24 or 25-29. In 1993, however, the 30-34 age group gave birth to the most babies of any 5-year age cohort for the first time in the state's recorded history. **The age-specific birth rates for women in this group were, however, greater in 1947 than in 1993 or 1994 (122.5, 97.5, and 98.4 births per 1,000 female population, respectively).**
- [5] From an exhaustive review of the medical literature for studies published between 1966 and 1995, it was recently suggested that nearly 30% of the racial gap in premature delivery (and associated low birthweight) may result from significantly higher rates of urogenital tract infections in black women than in women in other racial groups. (Fiscella, K. 1996. Racial Disparities in Preterm Births. The Role of Urogenital Infections. *Public Health Reports* 111: 104-113.)
- [6] Gestational age is calculated using the date of the last menstrual period (LMP) or the clinical estimate of gestational age, if the LMP is not available. Gestational age could not be determined for 1,908 (4.2%) of the resident births in 1994 (Table 3).
- [7] Analysis of 1989 infant mortality data from a linked birth-death file indicated under-reporting of Hispanic ethnicity by about 50% in standard, calendar-year tabulations.

- [8] Some of the leading causes of death used by the NCHS for infant deaths are:

ICD-9 code(s)	Cause of death
480-487	Pneumonia and influenza
740-759	Congenital anomalies
761	Newborn affected by maternal complications of pregnancy
762	Newborn affected by complications of placenta, cord, and membranes
765	Disorders relating to short gestation and unspecified low birthweight
768	Intrauterine hypoxia and birth asphyxia
769	Respiratory distress syndrome
771	Infections specific to the perinatal period
798.0	Sudden infant death syndrome
E-800-E949	Unintentional injuries

The adoption of the NCHS classifications for ranking infant death allows readers to make comparisons with national statistics more easily. The standard cause-of-death categories used by NCHS for infants are different than those used for older age groups. (See, for example, "Table 34. Leading causes of death and numbers of deaths, according to age: United States, 1980 and 1992," in *Health, United States, 1994*, National Center for Health Statistics, Hyattsville, Maryland, Public Health Service, 1995, p. 104.) Also, the NCHS classifications tend to be more narrow and specific than the categories used in prior Connecticut vital statistics reports. For example, the NCHS classification breaks the large category used in prior reports, "Conditions originating in the perinatal period" (ICD-9 codes 760-779), into smaller components, as noted in the table above and in Tables 8 and 10 of the present vital statistics report.

- [9] *Median Age at Death for CT Residents, 1989-1994*. Unpublished tables. Hartford: Connecticut Department of Public Health, Office of Policy, Planning and Evaluation.

- [10] Age-adjusted mortality rates for 1970 and 1980-1994 were calculated using 10-year age intervals, following the direct method. (Fleiss, J.L. 1981. *Statistical Methods for Rates and Proportions*. New York: John Wiley & Sons, p. 224-247.)

The direct method of adjustment requires age-and sex-specific population figures. Population data for different time periods were obtained from different sources, as noted below.

- a) The 1970 rate denominators were published in the Connecticut *Registration Report* for 1970.
- b) The 1980 rate denominators were published in the Connecticut *Registration Report* for 1980.
- c) The denominators used for the years 1981-1989 were the intercensal estimates published in: U.S. Bureau of the Census, *Preliminary Intercensal Estimates of the Population of States: 1981-1989*, November 1, 1991. The U.S. Bureau of the Census has revised these intercensal figures using the 1990 MARS data. These final intercensal figures vary little from the preliminary figures; hence, the 1981-1989

AAMRs were not recalculated using the final figures. The final intercensal figures are available upon request from the CT Department of Public Health.

- d) The 1990 denominators are the modified age, race, and sex population counts published by the U.S. Bureau of the Census. (U.S. Bureau of the Census. 1990. *Age, sex, race and Hispanic origin information from the 1990 Census: A comparison of census results with results where age and race have been modified*. Publ. No. 1990 CPH-L-74.)
- e) The 1991-1994 denominators were calculated based on two components:
 - (i) Connecticut population estimates published by the Connecticut Department of Public Health; and
 - (ii) age-sex population distributions for Connecticut published by the U.S. Bureau of the Census. The estimated Connecticut age-sex population counts were calculated by multiplying (i) and (ii), with appropriate rounding of the resulting figures.

Connecticut population estimates for 1991-1994 are given in:

- *Estimated Populations in Connecticut as of July 1, 1991*. Hartford: Connecticut Department of Health Services, Division of Health Surveillance and Planning, September, 1992.
- *Estimated Populations in Connecticut as of July 1, 1992*. Hartford: Connecticut Department of Public Health and Addiction Services, September, 1993.
- *Estimated Populations in Connecticut as of July 1, 1993*. Hartford: Connecticut Department of Public Health and Addiction Services, September, 1994.
- *Estimated Populations in Connecticut as of July 1, 1994*. Hartford: Connecticut Department of Public Health, Office of Policy, Planning & Evaluation, September, 1994.

The U.S. Census Bureau's estimated age-sex distributions of the Connecticut population are given in the following publications:

- Davis, S. *Estimates of the Population of States by Age, Sex, Race and Hispanic Origin: 1991*. U.S. Bureau of the Census, Population Division, 1994.
- Byerly, E. and K. Deardorff. *National and State Population Estimates: 1990-1994*. U.S. Bureau of the Census, Current Population Reports, p. 31-32. Washington, DC: U.S. Government Printing Office.

[11] The 1994 estimates of children affected by divorce may be low, as information about children under 18 in the household was missing from 4,584 divorce records (40.6% of total).

[12] *Birth Years of Husbands and Wives Divorced in Connecticut, 1994*. Unpublished worksheet. Hartford: Connecticut Department of Public Health, Office of Policy, Planning and Evaluation.

Notes: " - " Represents the quantity zero.

a Rates are not calculated for less than 5 events due to the high degree of variability associated with these figures.

1. Live birth and death rates are per 1,000 population.

2. Fetal and infant death rates are per 1,000 live births.

3. Caution is advised when analyzing marriage statistics which are based on the number of events occurring in a town or county and may or may not reflect the county or town of residence of either party. There were 7 records where county was unknown.

Notes: " - " Represents the quantity zero.

1. Race and ethnicity are separate categories. Individuals identifying themselves as "Hispanic" can be of any race and are also counted in the race breakdown as either white, black, or other. Only the main components of race and ethnicity are displayed (unknown race, unknown ethnicity and non-Hispanic are omitted). Readers should not expect the race and/or ethnicity components to sum to the total number of events. Overall, race was unknown for 1,185 of the births, 6 of the deaths and 1 of the fetal deaths. Ethnicity was unknown for 3,442 of the births, 986 of the deaths (19 for infant deaths) and 3 of the fetal deaths.
2. "Other" refers to the race category "Other Races".

Hispanic	915	11	14	6	78	501	295	10	3.4	12.0	86	539	290	13.8	

Notes: " - " Represents the quantity zero.

- a. Percents based on fewer than 5 events are not calculated due to the high degree of variability associated with these figures.
1. See Appendix III, Glossary, for explanation of marital status determination.
2. Timing of prenatal care refers to the pregnancy stage in which the first prenatal visit occurred (see Glossary).
3. Adequacy of prenatal care is based on a modified Kessner Index (see Glossary).
4. Percent premature is based on the number of premature births (less than 37 weeks) per 100 birth of known gestational age.
5. At the top of this table, under Mother's Ethnicity/Race, five mutually exclusive race/ethnicity groups are listed. As unknown ethnicity count is not given, the figures provided do not sum to the total for "All Races". There were 3,442 records with unknown ethnicity. After the top section of this table less detail is provided. Only the main components of the race/ethnicity categories are displayed.
6. "Live Birth Order" identifies the birth order of each child based on the current pregnancy and all previous pregnancies.

Note that the denominator in each percent calculation excludes records with missing information.

Notes: " - " Represents the quantity zero.

- a. Percents were not calculated for less than 5 events due to the high degree of variability associated with these figures.
- 1. Very low birthweight is defined as an infant weighing less than 1,500 grams at birth.
- 2. Low birthweight is defined as an infant weighing less than 2,500 grams at birth.
- 3. Late prenatal care is defined as prenatal care beginning in the second or third trimester of pregnancy.
- 4. Non-adequate prenatal care is defined as intermediate or inadequate prenatal care based on a modified Kessner Index.
- 5. At the top of this table, under Mother's Ethnicity/Race, five mutually exclusive race/ethnicity groups are listed. Since the unknown ethnicity count is not given, the figures provided sum to less than the total Connecticut count. There were 3,442 records with unknown ethnicity. After the top section of this table less detail is provided. Only the main components of the race/ethnicity categories are displayed.

Note that the denominator in each percent calculation excludes records with missing information.

NOTES: " - " Represents the quantity zero.

- a. Percents based on fewer than 5 events were not calculated due to the high degree of variability associated with these figures.
- 1. Fetal deaths do not include deaths that occurred prior to the 20th week of gestation (see Glossary).
- 2. Percent premature is based on the number of premature fetal deaths (less than 37 weeks) per 100 fetal death of known gestational age.
- 3. Records where race or ethnicity is unknown are not displayed. Overall, there was 1 record with unknown race and 3 with unknown ethnicity.

Notes: " - " Represents the quantity zero.

1. Race and ethnicity are separate categories. Individuals identifying themselves as "Hispanic" can be of any race and are also counted in the race breakdown as either white, black or other. Only the main components of race are displayed. Two components of ethnicity are also omitted (non-Hispanic and unknown ethnicity). Readers should not expect the race and/or ethnicity components to sum to the total number of events. "Other" refers to the race category "Other Races". In order to make this table more concise, counts for those of unknown race were omitted. Overall, there were 19 records with unknown ethnicity.

E960-E969 Homicide and injury purposely inflicted by other persons	4	2	2	-	1	-	-	-	-	-	4	2	2	-	1

Notes: " - " Represents the quantity zero.

1. Race and ethnicity are separate categories. Individuals identifying themselves as "Hispanic" can be of any race and are also counted in the race breakdown as either white, or other. Only the main components of race are displayed. Two components of ethnicity are also omitted (non-Hispanic and unknown ethnicity). Readers should not expect the race and/or the ethnicity components to sum to the total number of events. "Other" refers to the race category "Other Races." In order to make this table more concise, counts for those of unknown race are omitted. Overall, there were 19 records with unknown ethnicity.

Notes: " - " Represents 0 events.

1. For conciseness, only the main components of race and ethnicity are displayed. Consequently, the component race counts given (white and black) may sum to less than the All Races total. Counts for those of Hispanic ethnicity are displayed; however, figures for the two other ethnicity components (non-Hispanic and unknown ethnicity) are not displayed.

2. This category includes "All other infectious and parasitic diseases" belonging to the following ICD-9 cause-of-death classifications:

- | | |
|--|---|
| 01 - 09 Intestinal infectious diseases | 90 - 99 Syphilis and other venereal diseases |
| 20 - 41 Zoonotic bacterial diseases and other bacterial diseases | 100 - 104 Other spirochetal diseases |
| 45 - 49 Poliomyelitis and other non-arthropod-borne viral diseases of central nervous system | 110 - 118 Mycoses |
| 50 - 57 Viral diseases accompanied by exanthema | 120 - 129 Helminthiases |
| 60 - 66 Arthropod-borne viral diseases | 130 - 136 Other infectious and parasitic diseases |
| 70 - 79 Other diseases due to viruses and chlamydiae | 137 - 139 Late effects of infectious and parasitic diseases |
| 80 - 88 Rickettsioses and other arthropod-borne diseases | |

3. This category includes deaths resulting from accidents to watercraft causing submersion and drowning (E830), other accidental submersion or drowning in water transport accidents (E832) and accidental drowning and submersion (E910).

TABLE 10 (Continued)

Connecticut Residents, 1994:
Five Leading Causes of Death¹ by Age and Sex

Notes: 1 The leading causes of death are ranked within each age and sex category. Cause of death subgroup counts and rates are also provided where major cause of death groups are ranked in the top five. The causes are listed in rank order using the both sexes column first, followed by the male and the female columns.

2 Age-specific death rates and crude death rates are calculated per 100,000 population. The 1994 population counts presented in Table 1 were used as the denominators for these rates. Rates for persons under 1 year of age are an exception. For this group, rates are calculated per 1,000 live births. Denominators for the 1 to 4 age group were derived by subtracting 1993 resident births of known sex from the 0 to 4 age group population figure. Crude death rates for persons of all ages are provided at the end of Table 10. Since this last section of Table 10 is not age-specific, the rate column is labeled "Crude Death Rate per 100,000". Age of decedent is unknown for one record.

3 This category includes "All other infectious and parasitic diseases" belonging to the following ICD-9 cause-of-death classifications:

01 - 09 Intestinal infectious diseases	90 - 99 Syphilis and other venereal diseases
20 - 41 Zoonotic bacterial diseases and other bacterial diseases	100 - 104 Other spirochetal diseases
45 - 49 Poliomyelitis and other non-arthropod-borne viral diseases of central nervous system	110 - 118 Mycoses
50 - 57 Viral diseases accompanied by exanthema	120 - 129 Helminthiases
60 - 66 Arthropod-borne viral diseases	130 - 136 Other infectious and parasitic diseases
70 - 79 Other diseases due to viruses and chlamydiae	137 - 139 Late effects of infectious and parasitic diseases
80 - 88 Rickettsioses and other arthropod-borne diseases	

* There may be age and sex categories with fewer than 5 listed ranks. This is because there are either fewer than five leading causes or because causes with less than two reported deaths are not presented. There may also be causes of death which have the same number of deaths and therefore have the same rank within the category. Note also that unranked counts in parentheses "()" are provided in order to allow readers to examine the count distribution by gender.

TABLE 11
Number of This Marriage for Brides and for Grooms
in Marriages Occurring in Connecticut, 1994.

Number for Bride	Number for Groom								
	Total	First	Second	Third	Fourth	Fifth	Sixth	Seventh	Unknown
Total	22,720	16,137 ^a	5,485	927	114	22	3	1	31
First	16,246 ^a	13,609	2,341	249	24	4	-	-	19
Second	5,370	2,232	2,578	479	61	13	1	1	5
Third	886	222	466	173	20	5	-	-	-
Fourth	137	32	77	19	8	-	1	-	-
Fifth	17	4	8	5	-	-	-	-	-
Sixth	4	-	2	1	1	-	-	-	-
Seventh	3	-	1	1	-	-	1	-	-
Unknown	57	38	12	-	-	-	-	-	7

^a On Connecticut marriage certificates, the items, "No. of this marriage" and, "If previously married, last marriage ended by" appear as separate fields. Because the records with missing information are different for each field, the numbers of "first" marriages for brides and grooms in Table 11 do not necessarily match the numbers of "single" brides and grooms in Table 12.

TABLE 12
Marriages by Previous Marital Status of Bride and Groom,
Connecticut, 1994

Previous Marital Status of Bride	Previous Marital Status of Groom				
	Total	Single	Widowed	Divorced/Annulled	Unknown
Total	22,720	16,132 ^a	505	5,983	100
Single	16,241 ^a	13,604	99	2,490	48
Widowed	533	124	173	231	5
Divorced/Annulled	5,757	2,289	229	3,213	26
Unknown	189	115	4	49	21

^a On Connecticut marriage certificates, the items, "No. of this marriage" and, "If previously married, last marriage ended by" appear as separate fields. Because the records with missing information are different for each field, the numbers of "first" marriages for brides and grooms in Table 11 do not necessarily match the numbers of "single" brides and grooms in Table 12.

TABLE 13A
Number of Divorces by County,
Connecticut, 1994

County	Total

1969-1965	25-29	581
1964-1960	30-34	258
1959-1955	35-39	134
1954-1950	40-44	74
1949-1945	45-49	28
1944-1940	50-54	12
1939-1935	55-59	4
1934-1930	60-64	1
Before 1930	>63	-
Unknown	-	68

^a Duration of marriage is calculated by subtracting the year the marriage was contracted from the year it was dissolved.

Appendix I

RATE DEFINITIONS

$$\text{Age-specific birth rate} = \frac{\text{Number of live births in a specific age group}}{\text{Total resident population in specific age group}} \times 100,000$$

$$\text{Age-specific death rate} = \frac{\text{Number of deaths in a specific age group}}{\text{Total resident population in specific age group}} \times 100,000$$

$$\text{Crude birth rate} = \frac{\text{Number of resident live births}}{\text{Total resident population}} \times 1,000$$

$$\text{Crude death rate} = \frac{\text{Number of resident deaths}}{\text{Total resident population}} \times 1,000$$

$$\text{Divorce rate}^a = \frac{\text{Number of persons granted divorces}}{\text{Mid-year total resident population}} \times 1,000$$

$$\text{Fetal death rate}^b = \frac{\text{Number of fetal deaths}}{\text{Number of live births}} \times 1,000$$

$$\text{Infant death rate} = \frac{\text{Number of infant deaths}}{\text{Number of live births}} \times 1,000$$

$$\text{Marriage rate}^a = \frac{\text{Number of persons married}}{\text{Mid-year total resident population}} \times 1,000$$

^a Marriage and divorce counts provided in the tables in this report refer to number of *couples*, not *individuals*, who married or divorced. To calculate the marriage or divorce *rates*, the marriage or divorce counts were multiplied by two.

^b This fraction is often referred to as a *ratio*, rather than a *rate*, because the denominator (live births) does not contain the numerator (fetal deaths).

Appendix II

HEALTH DISTRICT DEFINITIONS USED IN 1994 REGISTRATION REPORT

Health District	Constituent Towns^a
Bristol-Burlington Health District	Bristol, Burlington
Chesprocott Health District	Cheshire, Prospect, Wolcott, Watertown
East Shore District Dept. of Health	Branford, East Haven, North Branford
Farmington Valley Health District	Avon, Barkhamsted, Canton, Colebrook, East Granby, Farmington, Granby, Hartland, New Hartford, Simsbury
Ledge Light Health District	City of Groton, Town of Groton
Naugatuck Valley Health District	Ansonia, Beacon Falls, Derby, Naugatuck, Seymour, Shelton
Newtown Health District	Town of Newtown, Borough of Newtown
North Central Health District	East Windsor, Ellington, Enfield, Suffield, Vernon, Windsor Locks
Northeast District Dept. of Health	Ashford, Brooklyn, Canterbury, Eastford, Hampton, Killingly, Plainfield, Pomfret, Putnam, Sterling, Thompson, Woodstock
Pomperaug Health District	Oxford, Southbury, Woodbury
Quinnipiack Valley Health District	Hamden, North Haven, Woodbridge
Stafford Health District	Stafford (Stafford Springs Borough), Union
Torrington Area Health District	Bethlehem, Cornwall, Goshen, Harwinton, Kent, Litchfield, Morris, Norfolk, Salisbury, Thomaston, Torrington, Warren, Winchester
Uncas Regional Health District	Montville, Norwich
West Hartford-Bloomfield Health District	Bloomfield, West Hartford
Weston-Westport Health District	Weston, Westport

^a Constituent towns are listed as of June 8, 1995.

GLOSSARY

Adequacy of prenatal care: See Kessner Index.

Age-adjusted death rate (Direct method): A summary of age-specific death rates, applied to a standard population (this report use the 1970 U.S. standard million) to calculate what rate would be expected if the selected population had the same distribution as the standard population. The total of expected deaths divided by the total of the standard population and multiplied by 100,000 yields the age-adjusted death rate per 100,000.

The 1970 U.S. standard million population distribution is shown below.

Age	Population	Age	Population
<5	84,416	50-54	54,643
5-9	98,204	55-59	49,077
10-14	102,304	60-64	42,403
15-19	93,845	65-69	34,406
20-24	80,561	70-74	26,789
25-29	66,320	75-79	18,871
30-34	56,249	80-84	11,241
35-39	54,656	85+	7,435
40-44	58,958	Total	1,000,000
45-49	59,622		

Age-specific birth rate: The number of live births to women in a specific age group per 1,000 females in the population in the same age group.

Age-specific death rate: The number of deaths in a specific age group per 1,000 population in the same age group.

Age-specific death rate: The number of deaths for a specific age group per 100,000 population in the same age group.

Birthweight: The first weight of a fetus or infant at time of delivery. This weight is usually measured during the first hour of life, before postnatal weight loss occurs.

Cause of death: The underlying cause of death determined to be the primary condition leading to death, based on the international rules and sequential procedure set forth for manual classification of the underlying causes of death by the National Center for Health Statistics and the World Health Organization (*International Classification of Disease, Ninth Revision*). (See also: "Underlying cause of death.")

Crude death rate: The number of deaths per 1,000 population. This rate should not be used for making comparisons between different populations when the age, race, and sex distributions of the populations are different. (See "Age-adjusted death rate" and "Age-specific death rate.")

Divorce: The final legal dissolution of a marriage.

Ethnicity: See "Hispanic ethnicity."

Fetal death: Death prior to the complete expulsion or extraction from the mother of a product of conception, which has passed through at least the 20th week of gestation. The fetus shows no signs of life such as heartbeat, pulsation of the umbilical cord, or movement of voluntary muscles.

Gestational age: The number of completed weeks elapsed between the first day of the last normal menstrual period (LMP) and the date of delivery.

Health district: A local governmental entity consisting of two or more towns that is responsible for the public health of its constituent towns. (See Appendix II for a listing of the 16 health districts in existence in Connecticut as of June 8, 1995.)

Hispanic ethnicity: Refers to people whose origins are from Spain, the Spanish-speaking countries of Central America, South America, and the Caribbean, or persons of Hispanic origin identifying themselves as Spanish, Spanish-American, Hispanic, Hispano, Latino, and so on. In Connecticut, the birth, death, and fetal death certificates have a separate line item for the individual's Hispanic status, to attempt to distinguish Hispanic ethnicity from race. Individuals identifying themselves as "Hispanic" can be of any race, and are also counted in the race breakdown as either "white," "black," or "other."

Infant death: Death occurring to an individual of less than one year (365 days) of age, comprising the sum of *neonatal death* and *postneonatal death*.

Kessner Index (Modified): The Kessner Index is a composite indicator of the adequacy of prenatal care a mother receives during her pregnancy. Prenatal care is categorized as *adequate*, *intermediate*, or *inadequate* based on three items from the birth certificate: timing of the first prenatal visit; total number of prenatal visits; and length of gestation. The term, *non-adequate* prenatal care, which is the sum of the intermediate and the inadequate levels of care, is used in Table 4 of the present report.

The modified Kessner Index used in this report differs from the usual definition in that more extensive efforts have been made to minimize the amount of missing information. In addition, certain extreme values of gestational age, which may have resulted from the mother's inability to recall the date of the last menstrual period, have been redefined as "missing" (about 1% of the records). A more detailed definition of the Modified Kessner Index and reference documents can be obtained from the Connecticut Department of Public Health, Office of Policy, Planning and Evaluation.

Live birth: The complete expulsion or extraction from the mother of a product of conception, regardless of the duration of pregnancy; after such separation, shows signs of life (e.g., heartbeat, pulsation of the umbilical cord, or movement of voluntary muscles).

Live birth order: The number of children born alive to the same mother, including the current birth (first born, second born, third born, etc.).

Low birthweight: A birthweight of less than 2,500 grams (approximately 5 lbs., 8 oz.).

Marital status: Because of statutory limitations, there is no "marital status" line item on Connecticut birth records. Marital status is inferred by comparing child's and parents' surnames. A birth is classified as occurring to a married couple if: 1) the parents' surnames are the same; or 2) if the child's and father's surnames are the same and the mother's current surname is missing in the birth certificate. A birth is classified as occurring to an unmarried couple if: 1) the father's name is missing; or 2) the parents' surnames are different.

Median age at death: The age that falls exactly in the middle of the entire range of ages ranked in order from low to high, such that 50% of the deaths fall above it and 50% fall below it. If the number of deaths is even, a value halfway between the two ages nearest the middle is used.

Neonatal death: Death occurring to an infant less than 28 days of age.

Occurrence: Place of occurrence identifies where the vital event actually took place, regardless of the place of residence of the individual.

Plurality: The number of siblings born as the result of a single pregnancy; commonly expressed as *singleton* or *multiple*.

Postneonatal death: Death occurring to an infant aged 28 days to 364 days.

Premature: A live birth or fetal death that occurs before the completion of the 37th week of gestation.

Race: A population of individuals who identify themselves from a common history, nationality, or geographical place. When responses in the "race" line item on vital records are associated with the definition of Hispanic origin, they are re-coded to "white race," as described in the National Center for Health Statistics instruction manuals for coding vital records. Individuals identifying themselves as either "white," "black," or "other" race can be of any ethnic group. (See also "Hispanic ethnicity.")

Residence: The usual place of abode of the person to whom the vital event occurred. For births and fetal deaths, residence is defined as the mother's usual place of residence.

Teenage mother: A woman under 20 years of age on the date of delivery.

Trimester of pregnancy: One-third of the total gestation period of a full-term pregnancy, or 13 weeks per trimester. The "third trimester" classification comprises pregnancies of 27 or more weeks gestation. The weekly count begins on the first day of last menstrual period.

Underlying cause of death: The disease or injury that initiated the sequence of events leading directly to death, or the circumstances of the accident or violence that produced the fatal injury.

Very low birthweight: A birthweight of less than 1,500 grams (approx. 3 lbs., 5 oz.).

Appendix IV

AGE-ADJUSTED MORTALITY RATES FOR SELECTED CAUSES OF DEATH
1970 AND 1980-1994

(Deaths per 100,000 population^a)

Cause of Death	Year of Death

^a Mortality rates were adjusted to the 1970 U.S. standard million population, using the direct method.

^b COPD = Chronic obstructive pulmonary disease (emphysema, chronic bronchitis, etc.).

^c HIV = Human Immunodeficiency Virus. Cause-of-death codes for HIV infection were not available until 1987.

Notes: " - " Represents the quantity of zero.

" a " Percents are not calculated for less than 5 events due to the high degree of variability associated with these figures.

1. Very low birthweight is defined as an infant weighing less than 1,500 grams at birth.
2. Low birthweight is defined as an infant weighing less than 2,500 grams at birth.
3. Late prenatal care is defined as prenatal care beginning in the second or third trimester of pregnancy.
4. Non-adequate prenatal care is defined as intermediate or inadequate prenatal care based on a modified Kessner Index.

* Selected Connecticut towns with one thousand or more births to residents. These 8 towns account for about 31% of all resident births and 74% of births to Hispanic mothers.
