WHAT IS THE PURPOSE OF THE REPORT?

This report is meant to provide healthcare-associated infection (HAI) information in an understandable way to enable readers to view facility-specific HAI performance, evaluate interventions to drive change within a facility, understand the state's HAI performance as a whole, and/or to compare a facility's HAI performance to others in the state and the rest of the country.

In addition to tracking and reporting HAIs for their own quality improvement initiatives, Connecticut healthcare facilities are required to track and report HAIs in Connecticut to the state health department, and most also do so to fulfill requirements of the federal Centers for Medicare and Medicaid Services (CMS) or other payors. Such tracking and reporting can greatly improve the care patients receive. Healthcare facilities report data about HAIs because they want to know how well they are doing in preventing them. They also can compare themselves with facilities of similar size and with similar kinds of patients to help interpret the data and focus efforts on the most important HAIs to the greatest benefit.

Patients and their family members can also use this information to ask healthcare providers questions before seeking and while receiving medical treatment. A consumer-oriented version of this report is also available.

This report looks at six types of HAIs:

1. Central line-associated bloodstream infections (CLABSI)
2. Catheter-associated urinary tract infections (CAUTI)
3. Surgical site infections (SSI) following colon surgeries and abdominal hysterectomies
4. Positive laboratory results with methicillin-resistant *Staphylococcus aureus* (MRSA) bacteria found in the bloodstream
5. Positive laboratory results with *Clostridium difficile* (*C. difficile*) in stool
6. Dialysis events in hemodialysis centers. In this report data is presented on local access site infections (LASI), and bloodstream infections (BSI).

Healthcare facilities are required by the Connecticut Department of Public Health (DPH) to report these six types of HAIs. More information about Connecticut's mandatory reporting can be found here: <http://www.ct.gov/dph/cwp/view.asp?a=3136&q=557832>

These measures do not represent all possible infections, but were selected by CMS and the DPH to give an overview of how a healthcare facility is doing in preventing healthcare-associated infections. These infections are largely preventable when healthcare providers use infection prevention steps recommended by the Centers for Disease Control and Prevention (CDC) and by the Connecticut Department of Public Health (CT DPH).

HOW DO I READ THE REPORT?

Standardized Infection Ratio

Using a measure called the *standardized infection ratio* (SIR), this report looks at the HAI performance of healthcare facilities in this state by displaying the number of certain HAI types they reported during 2016. The SIR shows whether a healthcare facility had significantly more HAIs, fewer HAIs, or about the same number of HAIs compared to the number predicted for that healthcare facility based on national baseline data and state data.

The SIR is a summary measure that can be used to track HAIs over time and can be calculated on a variety of levels, including unit, facility, state, and nation. It adjusts for differences between healthcare facilities such as types of patients and procedures, as well as other factors such as the facility's size and whether it is affiliated with a medical school (see page 6 for more information about risk adjustment). It compares the number of infections reported in a given time period to the number of infections that were predicted using data from a baseline time period. Lower SIRs indicate better performance.

When the SIR is calculated, there are three possible results:

- The SIR is **less than 1.0** – this indicates that there were fewer infections reported during the surveillance period than would have been predicted given the baseline data.
- The SIR is **equal to 1.0** – the value of 1 indicates that the numerator and denominator are equal. In this case, the number of infections reported during the surveillance period is the same as the number of infections predicted given the baseline data.
- The SIR is **greater than 1.0** – this indicates that there were more infections reported during the surveillance period than would have been predicted given the baseline data.

Rates

Local access site infection in outpatient hemodialysis centers, one of the HAI measures, were calculated using rates rather than the SIR. An infection rate measures the number of new infections seen in a healthcare facility during a given time period for those patients at risk for infection.

A rate is calculated for each infection/event type (i.e., local access site infections in dialysis) as the total number of infections or events reported during 2016, divided by the total number of days or months that patients were at risk for that infection or event.

WHAT DO THE NUMBERS MEAN?

The number of infections alone will not show how well a healthcare facility is doing in preventing HAIs, more information and analysis is needed—that is what the SIR or rates provide. This report shows how healthcare facilities performed during a single year (2016), and compares each facility's performance to the national baseline and to the statewide SIR. The statewide SIR or rates for a given year are specified in the data section of this report. For the purposes of comparison to the nation, **the national baseline SIR is always 1.0.**

Infection rates and SIRs are calculated using a numerator (number of infections) and a denominator (population at risk). Readers should evaluate the numerator and denominator as well as the SIR or rate in order to obtain an accurate picture of the facility's infection experience. Larger facilities that see more patients or do more surgeries may have more infections compared to smaller facilities. Therefore, it is important not only to consider the number of infections for each facility, but to also look at size of the facility and the total number of procedures performed in that time period.

Although HAIs are a significant patient safety and public health concern, they are not the only available quality metric, and other quality measures should be considered in assessing the overall quality of care.

WHERE DO THE NUMBERS COME FROM?

Healthcare facility staff self-report their HAI data to the CDC and the DPH using a free, web-based software system called the National Healthcare Safety Network (NHSN). CDC and the DPH HAI program provides training to hospital staff on the use of this system and provides guidance on how to track infections with standard methods.

Efforts are made through education and training to improve the standardization and understanding of NHSN surveillance guidelines,

case definitions, other definitions relevant to risk adjustment and case classification, and case finding methods. However, there can be variability in interpretation of the case definitions and application of the reporting protocols, leading to differences in reporting practices among facilities. Furthermore, facilities with more resources and/or a robust HAI surveillance program may be able to identify and report more infections compared to a facility with fewer resources.

The SIR calculation compares the number of reported HAIs from a facility or location (ward or ICU) to reports from similar facilities or locations during a baseline period. The initial baselines for the various HAIs (e.g., CLABSI, CAUTI) were developed at different times during 2006-2013. To standardize and update SIR reports, new baselines collected during one recent year were needed. New baselines were developed in 2015; this process is called "rebaselining." The SIRs in this report of 2016 HAI data in Connecticut uses the new 2015 baselines. The effect of rebaselining is to set the SIR for facilities and locations generally back to or close to 1, and then track progress from the new baseline period. This can make tracking of trends before the rebaselining difficult. When NHSN rebaselined, they also revised the mathematical formulas that calculate the expected number of infections needed to calculate the SIR.

These reports cover data that were collected during 2016 and were downloaded from NHSN on May 25, 2017; except for CLABSI, which were downloaded on July 11, and CAUTI, downloaded on July 21, after NHSN model revisions; any changes made to the data after this date are not reflected in this report. More information about NHSN can be found here: <http://www.cdc.gov/nhsn/>

LABORATORY-IDENTIFIED (LABID) EVENT ANALYSES

Clostridium difficile infection (CDI) and methicillin-resistant *Staphylococcus aureus* (MRSA) bacteremia LabID events rely on laboratory data. Patients do not have to meet clinical criteria for their events to be reported to NHSN, which allows for a much less labor-intensive means to track CDI and MRSA infections. LabID events that occurred more than three calendar days after admission are considered healthcare associated and counted.

LabID event counts tend to be higher than definitions based on clinical criteria. This may be due to differences in how individual facilities define and classify clinical disease, when specimens are obtained, and variations in hospital laboratory testing methods and practices. LabID events should be considered a ‘proxy’ measure to estimate the number of CDI and MRSA infections actually occurring.

Despite these caveats, there are benefits to using LabID data. LabID events do not depend on clinical interpretation by providers and thus offer a more standardized and consistent method of collecting and reporting CDI and MRSA surveillance data.

Moreover, LabID events are currently being used by CMS for quality reporting programs. Improving prevention practices as described in existing clinical guidelines should result in a decrease in the number of observed CDI and MRSA LabID events as well as a decrease in the number of clinically-defined infections.

HAI RISK ADJUSTMENT

SIRs are adjusted for risk factors that may affect the number of infections reported by a healthcare facility, such as type of patient care location, bed size of a hospital, patient age, and other factors. The SIR is adjusted differently depending on the type of infection measured.

The SIRs for CLABSIs and CAUTIs are adjusted for:

- Type of patient care location
- Hospital affiliation with a medical school (for some units)
- Bed size of the patient care location (for some units)

The SIRs for hospital-onset *C. difficile* and MRSA bloodstream LabID events are adjusted using slightly different risk factors:

- Facility bed size
- Hospital affiliation with a medical school
- The number of patients admitted to the hospital who already have a *C. difficile* or an MRSA bloodstream LabID event (“community-onset” cases)
- For hospital-onset *C. difficile*, the SIR also adjusts for the type of test the hospital laboratory uses to identify *C. difficile* from patient specimens

The SSI SIRs are presented using CDC’s Complex Admission/Readmission (A/R) model, which takes into account patient differences and procedure-related risk factors within each type of surgery. These risk factors include:

- Duration of surgery
- Surgical wound class
- Use of endoscopes
- Re-operation status for orthopedic surgeries (e.g., knee replacement, hip replacement)
- Patient age
- Patient assessment at time of anesthesiology

When rates are used, the data have a limited risk-adjustment that may not take into account patient or facility differences that could contribute to the incidence of HAIs.

STATISTICAL SIGNIFICANCE

The p-value and 95% confidence interval are statistical measures that describe the likelihood that what is observed might be explained by random chance.

HAI measures

For HAIs and LabID events, the p-value and confidence interval show whether or not a facility's SIR is significantly different from 1.0 (the value we would expect if the facility performed exactly the same as what was predicted based on the national data). If the p-value is less than or equal to 0.05 (1/20th), one can conclude that the number of observed infections is *significantly different* from the number of predicted infections (i.e., the facility's SIR is significantly different from 1.0). If the p-value is greater than 0.05, one should conclude that the number of observed infections in a facility is *not significantly different* from the number predicted (i.e., not significantly different than 1.0).

The 95% confidence interval is a range of values. One can have a high degree of confidence (in this case, 95%) that the true SIR lies within this range. The upper and lower limits are used to determine the significance and accuracy (or precision) of the SIR. For national comparison, if 1.0 falls within the confidence interval, then the SIR is *not significant* (i.e., the number of observed events is not significantly different from the number predicted). If 1.0 falls outside the confidence interval, then the SIR is *significant*. For state comparison, the statewide SIR is substituted for 1.0. When the SIR is zero, the lower bound of the 95% confidence interval cannot be calculated. However, for ease of interpretation, it can be considered zero. In data presentation, statisticians show this with a blank space followed by a comma, for instance, (, 0.94).

QUALITY ASSURANCE AND DATA VALIDATION

As noted earlier, there may be differences in reporting practices and the

efficacy of surveillance among healthcare facilities. For example, healthcare facilities with more infection control staff to count infections may be able to identify and report more infections compared to a healthcare facility with fewer infection control staff.

Reported data collected by NHSN in this report are self-reported by staff of healthcare facilities. The 2016 data have not been independently verified by public health staff through review of patient charts. However, DPH HAI Program staff check the data for outliers and unexpected results, and periodically checks in with facilities' reporting staff to make sure the reported numbers are correct., including just before freezing the data for this report.

OTHER DATA CAVEATS AND LIMITATIONS

There may be small variations between results published by the CT DPH HAI Program and results published elsewhere (e.g., CMS Hospital Compare). This is expected and can be due for various reasons. Healthcare facilities have the ability to modify their data to update it in NHSN at any time once entered, and as such, results may appear to vary if other sources use different data collection periods or report cutoff dates than Connecticut's reports. Alternatively, the same data may be analyzed and reported using slightly different criteria for analysis of reporting. For example, SSIs can be reported using different length of follow-up.

The CT DPH HAI Program does not calculate an SIR when the number of predicted infections is less than 1.0. In these situations, the SIR cannot be calculated in accordance with the threshold based on CDC recommendations. If the number is lower than the threshold, it means there is too little data and the effect of chance is comparatively too great to judge the facility's performance on this measure. In these situations, the comparison to the nation and the statewide SIR is left blank.

DATA PRESENTED IN THIS REPORT

The following tables summarize findings about HAI in Connecticut's healthcare facilities. Included are the following:

- Acute care hospitals (ACH)
- Long-term acute care hospitals (LTACH)
- Inpatient rehabilitation facilities (IRF)
- Outpatient hemodialysis facilities

CMS assigns each Connecticut facility to one of these facility types. For facility classification in this report, we are using the CMS assignments.

In addition to being presented on facility level, the various HAI are also tracked on unit level: in adult or pediatric ICUs or wards, for example. Because levels of infections can vary between these different units, this more detailed information is important, as it can provide information more relevant for specific infection control measures.

Types of HAI presented in this report:

- CLABSI: Central line-associated blood stream infections
- CAUTI: Catheter-associated urinary tract infections
- SSI: Surgical site infections (colon surgeries and abdominal hysterectomies)
- MRSA: methicillin-resistant *Staphylococcus aureus* bacteremia
- CDI: *Clostridium difficile* infections

Not all of these infections are presented for each facility or each unit within the facility. This is either because they are not required to report the data to DPH, or because relevant procedures are not performed at that facility or unit.

FACILITIES' PERFORMANCE

Facilities' performance in HAI prevention is shown by comparing them to other facilities adjusting for their risk for HAIs to both the state and to the national baseline. Using the SIR, two values are reported: the number of observed infections, and the number of predicted infections, which is calculated by the CDC based on risk adjustment measures described earlier in this report.

Using these two values, we can find out how a given facility or unit is performing compared to both the state average and the national baseline. We used the following graphics in this report to show how a facility is performing :

 = compared to the state or national SIR, the facility's SIR is statistically significantly better for this HAI

 or  = the facility's SIR is not statistically significantly different from the national or state SIR; the direction of the arrow indicates whether the SIR is likely lower or higher

 = the facility is doing statistically significantly worse

In some cases, the cells for comparison are left empty. This is because in these facilities or units, the predicted number was determined to be less than 1. In accordance with CDC protocol, the SIR for these facilities cannot be calculated, and so we cannot draw a conclusion about how the facility compares.

LEGEND

2016 facility rate is significantly lower (better) than comparison group rate (state or national)

2016 facility rate is significantly higher (worse) than comparison group rate (state or national)

2016 facility rate is not statistically significantly different from the comparison group (state or national) rate. If arrow points up, the rate is worse (but not significantly so), if it points down, it is better (but not significantly so).

Note: A rate is calculated for each infection type in dialysis facilities as the total number of infections reported during 2016, divided by the total number of months that patients were at risk for that infection.

Hemodialysis LASI 2016 rate	
State	0.88/100 patient-months
National	0.72/100 patient-months

FACILITY NAME	Patient months	Observed infections	Rate (observed events per 100 patient-months)	How does this facility compare?	
				State	Nation
Black Rock Dialysis	951	7	0.74	↓	↑
Bloomfield Dialysis	639	2	0.31	↓	↓
Branford Dialysis	527	3	0.57	↓	↓
Bridgeport Dialysis	2,484	39	1.57	↑	↑
Central Connecticut Dialysis Center	498	3	0.60	↓	↓
Comprehensive Dialysis Care, LLC	599	6	1.00	↑	↑
Danbury Dialysis Center	1,278	12	0.94	↑	↑
DaVita Waterbury Heights Dialysis	728	10	1.37	↑	↑
Dialysis Center Of Newington	538	1	0.19	↓	↓
East Hartford Dialysis Center	1,053	0	0.00	↓	↓

What healthcare providers can do to prevent infection

To prevent any type of infection:

- Follow standard and transmission-based precautions meticulously, use appropriate personal protective equipment, and perform hand hygiene as indicated.
- Ensure that all medical devices and equipment are cleaned, disinfected, sterilized, and/or discarded appropriately.
- Ensure the environment of care is maintained appropriately.
- Speak up if you see co-workers who are not following appropriate infection prevention measures.
- Ensure that information about infection and colonization is communicated during transitions of care.

To prevent central line-associated bloodstream infections (CLABSIs) and catheter-associated urinary tract infections (CAUTIs):

- Follow recommended device insertion practices.
- Follow recommended device maintenance practices.
- Every day, evaluate whether the device is still needed. Ensure it is removed as soon as it is no longer needed.

To prevent surgical site infections:

- Follow a safe surgery checklist before, during, and after surgery.
- When indicated, give an antibiotic before surgery. Make sure the dose is appropriate and the drug is discontinued in a timely manner.
- Follow recommendations for hand hygiene, personal protective equipment, and antiseptic skin preparation.
- Post-discharge, provide the patient with wound care instructions and education on symptoms of infection.

To prevent *Clostridium difficile* infections:

- Use antibiotics judiciously.
- Implement contact precautions for patients with known or suspected *C. difficile* infection.
- Ensure proper cleaning and disinfection of the environment.

To prevent methicillin-resistant *Staphylococcus aureus* (MRSA) infections:

- Ensure compliance with contact precautions for MRSA-colonized and infected patients.
- Ensure proper cleaning and disinfection of the environment.
- Implement an alert system to enable prompt notification of laboratory-identified or readmitted patients with MRSA to allow timely initiation of control measures.

To prevent influenza infections:

- Get vaccinated against the flu each year.
- Promote good respiratory hygiene practices.
- Encourage people in common areas who have respiratory symptoms to distance themselves from others or wear a surgical mask, if they are able to tolerate it.
- Implement droplet precautions for patients with influenza.
- Administer antiviral treatment and chemoprophylaxis to patients and healthcare personnel when appropriate.
- If sick with flu-like illness, stay home for at least 24 hours after fever subsides and limit contact with other people.

List of acronyms

ABBREVIATION	DEFINITION
ACH	Acute care hospital (short-term)
BSI	Bloodstream infection
CAUTI	Catheter-associated urinary tract infection
CDC	Centers for Disease Control and Prevention
CDI	<i>Clostridium difficile</i> infection
CHA	Connecticut Hospital Association
CI	Confidence Interval
CLABSI	Central line-associated bloodstream infection
CMS	Centers for Medicare and Medicaid Services
COLO	NHSN code for surgical site infection following colon surgical procedures
CUSP	Comprehensive Unit-based Safety Program
DE	Dialysis event
DHHS	Department of Health and Human Services
DPH	Connecticut Department of Public Health
DU	Device utilization
FacWideIN	Facility-wide inpatient

ABBREVIATION	DEFINITION
HAI	Healthcare associated infection
HO	Hospital-onset
HYST	NHSN code for surgical site infection following abdominal hysterectomies
ICU	Intensive care unit
IP	Infection Preventionist
IPPS	Inpatient Prospective Payment System
IRF	Inpatient rehabilitation facility
LTACH	Long-term acute care hospital
MRSA	Methicillin-resistant <i>Staphylococcus aureus</i>
NHSN	National Healthcare Safety Network
NICU	Neonatal intensive care unit
PICU	Pediatric intensive care unit
QI	Quality improvement
QIP	Quality Incentive Program
SIR	Standardized infection ratio
SSI	Surgical site infection
