RE: **Letter of Intent**

The Waterbury Hospital and Saint Mary's Hospital Corporation, d/b/a/ Heart Center of Greater Waterbury and University of Connecticut Health Center/John Dempsey Hospital

Dear Commissioner Vogel:

Enclosed please find an original and three (3) copies of our Letter of Intent Form 2030 for your consideration. The Applicants seek to continue to serve the greater Waterbury community with advanced cardiac services through the CON process. Your attention to this is greatly appreciated.

Should you require additional information or have any questions concerning this matter please contact:

Loraine C. Shea, Executive Director
Heart Center of Greater Waterbury
PO Box 2153
Waterbury, CT 06722
(P) 203-575-5571
(F) 203-575-5575

Sincerely,

Saint Mary's Hospital

William Casey,
President and CEO

The Waterbury Hospital

Steven Schneider, MD
Vice President of Medical Affairs

John Dempsey Hospital

Ellen M. Leone, RN MSN
Associate VP of Operations and Director of Nursing

State of Connecticut
Office of Health Care Access
Letter of Intent Form
Form 2030

RECEIVED
2008 JUL -8 P 3:05
CONNECTICUT OFFICE OF
HEALTH CARE ACCESS

All Applicants involved with the proposal must be listed for identification purposes. A proposal's Letter of Intent (LOI) form must be submitted prior to a Certificate of Need application submission to OHCA by the Applicant(s), pursuant to Sections 19a-638 and 19a-639 of the Connecticut General Statutes and Section 19a-643-79 of OHCA's Regulations. Please complete and submit Form 2030 to the Commissioner of the Office of Health Care Access, 410 Capitol Avenue, MS# 13HCA, P.O. Box 340308, Hartford, Connecticut 06134-0308.

SECTION I. APPLICANT INFORMATION

If this proposal has more than two Applicants, please attach a separate sheet, supplying the same information for each additional Applicant in the format presented in the following table.

	Applicant One	Applicant Two
Full legal name	The Waterbury Hospital (WH)	Saint Mary's Hospital, Inc. (SMH)
Doing Business As	Heart Center of Greater Waterbury (HCGW)	Heart Center of Greater Waterbury (HCGW)
Name of Parent Corporation	Greater Waterbury Health Network	Saint Mary's Health System, Inc.
Applicant's Mailing Address, if Post Office (PO) Box, include a street mailing address for Certified Mail (Zip Code Required)	64 Robbins St. Waterbury, CT 06721	56 Franklin St. Waterbury, CT 06706
Identify Applicant Status: P for Profit or NP for Nonprofit	NP	NP
Does the Applicant have Tax Exempt Status?	Yes	Yes
Contact Person, including Title/Position: This Individual will be the Applicant Designee to receive all correspondence in this matter.	Loraine Shea, Executive Director HCGW	Loraine Shea, Executive Director HCGW
Contact Person's Mailing Address, if PO Box, include a street mailing address for Certified Mail (Zip Code Required)	PO Box 2153 Waterbury, CT 06722 OR 1075 Chase Pkwy Waterbury, CT 06708	PO Box 2153 Waterbury, CT 06722 OR 1075 Chase Pkwy Waterbury, CT 06708

SECTION II. GENERAL APPLICATION INFORMATION

a. Project Title:

Response: Advanced Cardiac Services Program

b. Project Proposal:

Response: Provision of Elective and Primary Angioplasty and Open Heart Surgery

c. Type of Project/Proposal, please check all that apply:

Inpatient Service(s):

☐ Medical/Surgical ☒ Cardiac ☐ Pediatric ☐ Maternity
☐ Trauma Center ☐ Transplantation Programs
☐ Rehabilitation *(specify type)* _____
☐ Behavioral Health (Psychiatric and/or Substance Abuse Services)
☐ Other Inpatient *(specify)* _____

Outpatient Service(s):

☐ Ambulatory Surgery Center ☐ Primary Care ☐ Oncology
☐ New Hospital Satellite Facility ☐ Emergency ☐ Urgent Care
☐ Rehabilitation *(specify type)* _____ ☐ Central Services Facility
☐ Behavioral Health (Psychiatric and/or Substance Abuse Services)
☐ Other Outpatient *(specify)* _____

Imaging:

☐ MRI ☐ CT Scanner ☐ PET Scanner
☐ CT Simulator ☐ PET/CT Scanner ☐ Linear Accelerator
☐ Cineangiography Equipment ☐ New Technology: _____

Non-Clinical:

☐ Facility Development ☐ Non-Medical Equipment ☐ Renovations
☐ Change in Ownership or Control ☐ Land and/or Building Acquisitions
☐ Organizational Structure (Mergers, Acquisitions, & Affiliations)
☐ Other Non-Clinical: _____

d. Does the proposal include a Change in Facility (F), Service (S)/Function (Fnc) pursuant to Section 19a-638, C.G.S.?

☒ Yes ☐ No

If you checked "Yes" above, please check the appropriate box below:

☐ New (F, S, Fnc) ☐ Additional (F, S, Fnc) ☒ **Replacement**

☐ Expansion (F, S, Fnc) ☐ Relocation ☐ Termination of Service

☐ Reduction ☐ Change in Ownership/Control

e. Will the Capital Expenditure/Cost of the proposal exceed $3,000,000, pursuant to Section 19a-639, C.G.S.?

☐ Yes ☒ No

If you checked "Yes" above, please check the boxes below, as appropriate:

☐ New equipment acquisition and operation

☐ Replacement equipment with disposal of existing equipment

☐ Major medical equipment

☐ Change in ownership or control

f. Location of proposal, identifying Street Address, Town and Zip Code:

Response: 64 Robbins Street Waterbury, CT 06721 and 56 Franklin Street Waterbury, CT 06708

g. List each town this project is intended to serve:

Response: The Primary service area of Saint Mary's Hospital and Waterbury Hospital has traditionally included Beacon Falls, Bethlehem, Cheshire, Middlebury, Naugatuck, Prospect, Southbury, Thomaston, Waterbury, Watertown, Wolcott, and Woodbury.

h. Estimated starting date for the project:

Response: Immediately so as to have no interruption in services currently being provided to ensure patient access and safety.

i. If the proposal includes change in the number of beds provide the following information:

Type	Existing Staffed	Existing Licensed	Proposed Increase or (Decrease)	Proposed Total Licensed

Response: Not Applicable

SECTION III. ESTIMATED CAPITAL EXPENDITURE/COST INFORMATION

a. Estimated Total Project Expenditure/Cost:

Response: All necessary renovations and major medical equipment purchases occurred under previously authorized CON. (Docket # 03-30167-CON) No additional costs are associated with this project.

b. Please provide the following tentative capital expenditure/costs related to the proposal:

Major Medical Equipment Purchases*	
Medical Equipment Purchases*	
Non-Medical Equipment Purchases*	
Land/Building Purchases	
Construction/Renovation	
Other (Non-Construction) Specify:_____	
Total Capital Expenditure	
Major Medical Equipment – Fair Market Value of Leases Medical	
Equipment – Fair Market Value of Leases	
Non-Medical Equipment – Fair Market Value of Leases*	
Fair Market Value of Space – Capital Leases Only	
Total Capital Cost	
Total Project Cost	
Capitalized Financing Costs (Informational Purpose Only)	

* Provide an itemized list of all medical and non-medical equipment to be purchased and leased.

Response: Not Applicable

c. If the proposal has a total capital expenditure/cost exceeding $20,000,000 or if the proposal is for major medical equipment exceeding $3,000,000, you may request a Waiver of Public Hearing pursuant to Section 19a-643-45 of OHCA's Regulations? Please check your preference.

☐ Yes ☒ No

Response: Not Applicable

1. If you checked "Yes" above: please check the appropriate box below indicating the basis of the projects eligibility for a waiver of hearing

☐ Energy Conservation ☐ Health, Fire, Building and Life Safety Code

☐ Non Substantive

2. Provide supporting documentation from elected town officials (i.e. letter from Mayor's Office)

Response: See Appendix I

d. Major Medical and/or Imaging Equipment Acquisition:

Equipment Type	Name	Model	Number of Units	Cost per unit

Note: Provide a copy of the vendor contract or quotation for each major medical/imaging equipment.

Response: Not Applicable

e. Type of financing or funding source (more than one can be checked):

☐ Applicant's Equity ☐ Capital Lease ☐ Conventional Loan

☐ Charitable Contributions ☐ Operating Lease ☐ CHEFA Financing

☐ Funded Depreciation ☐ Grant Funding

☐ Other *(specify)* _____

Response: Not Applicable

SECTION IV. PROJECT DESCRIPTION

In paragraph format, please provide a description of the proposed project, highlighting each of its important aspects, on at least one, but not more than two separate 8.5" X 11" sheets of paper. At a minimum each of the following items need to be addressed, if applicable.

Response: SEE PAGE 7

1. List the types of services are currently being provided. If applicable, provide a copy of each Department of Public Health (DPH) license held by the Applicant.

2. List the types of services being proposed and what DPH licensure categories will be sought, if applicable.

3. Identify the current population served and the target population to be served.

4. Identify any unmet need and describe how this project will fulfill that need.

5. Are there any similar existing service providers in the proposed geographic area?

6. Describe the anticipated effect of this proposal on the health care delivery system in the State of Connecticut.

7. Who will be responsible for providing the service?

8. Who are the current payers of this service and identify any anticipated payer changes when the proposed project becomes operational?

Section IV. PROGRAM DESCRIPTION

1. List the types of services that are currently being provided. If applicable, provide a copy of each Department of Public Health (DPH) license held by the Applicant.

Response: The Heart Center of Greater Waterbury (HCGW) has a longstanding history of providing cardiac services to patients of the greater Waterbury area. Since July 18, 2005, the HCGW in conjunction with John Dempsey Hospital has substantially improved the quality of medicine and in particular, cardiac care by successfully providing advanced cardiac services including open heart surgery and angioplasty services (Program) as a compliment to other vital cardiac services such as pacemaker clinics, cardiac rehabilitation, inpatient critical care and emergency room care. The greater Waterbury area relies on the HCGW, Saint Mary's Hospital and Waterbury Hospital to continue to provide these lifesaving services close to home. As will be demonstrated in the formal Certificate of Need application, over 2,400 residents have experienced and come to rely upon a higher level of quality and comprehensive cardiac care. (See Appendix II for copies of acute care hospital licenses)

2. List the types of services being proposed and what DPH licensure categories will be sought, if applicable.

Response: The applicants are proposing to replace the existing services previously approved as a demonstration project with an advanced cardiac services program under the direction of a new CON. These services are currently provided under the hospitals' current acute care hospital licenses.

3. Identify the current population served and the target population to be served.

Response: The Program currently serves and seeks to continue to serve the adult population in the greater Waterbury area. The Program's primary service area consists of twelve surrounding towns and is noted on page 4. Coronary artery disease is the number one cause of death in the nation and in Connecticut. The growth in total population in the primary service area from 2000 to 2006 was 5.0%. It is expected to grow by an additional 3.0% to 281,800 by 2011. The population over 45 years of age in 2006 was 40.5% of the total population. This is expected to increase through 2011 to 43.6% of the total population. (Claritas Inc.) The female portion of the population over 45 years of age in 2006 was 54.4% of the total. The female portion of the population over 45 years of age is expected to remain at this level through 2011. This is critical in the consideration of future cardiac care needs because it has been shown that coronary artery disease in the female population has been under diagnosed in the past and women have a longer life expectancy than men. Current data for the Program demonstrate the majority of patients treated for open heart surgery since July, 2005 have been over the age of 65 years and have several cardiac risk factors such as diabetes, hypertension and hyperlipidemia. As recognized in the public hearing transcripts in Docket # 03-30167-CON, patients and their families found it very difficult to travel away from their greater Waterbury communities for advanced, lifesaving services prior to July 18, 2005. Having such advanced cardiac services offered locally through the HCGW has not only eliminated these difficulties, but greatly improved their quality of care and their quality of life.

4. Identify any unmet need and describe how this project will fulfill that need.

Response: Since July 18, 2005, the demonstration project has met the cardiac needs of the greater Waterbury area. Over the initial three years, the Program's market share for angioplasty procedures has grown to 78%. For Coronary Artery Bypass Graph (CABG) Surgery and Cardiac Valve Surgery respectively market share has grown to 76% and 57% respectively. On an average, at least 100 ST-Elevation Myocardial Infarction (STEMI) patients received acute angioplasty each year. The program is demonstrating that it is able to revascularize these patients in an average of 66 minutes. In addition, 88% of the STEMI patients are being revascularized in less than 90 minutes, far exceeding the national benchmark of 75%. The program has consistently demonstrated excellent outcomes and exceptional service for its patients and families. This replacement Program under the direction of a new CON will continue to meet the immediate needs of the cardiac patients in a quality and cost efficient manner

5. Are there any similar existing service providers in the proposed geographic area?

Response: The Heart Center of Greater Waterbury is currently the sole provider of advanced cardiac services in the greater Waterbury area. The addition of these services in 2005 has allowed over 2,400 community members and their families the ability to be cared for locally in their community hospital and by local physicians with excellent quality outcomes, in an environment with which they are comfortable and by providers in whom they have tremendous confidence.

6. Describe the anticipated effect of this proposal on the health care delivery system in the State of Connecticut.

Response: This replacement Program under the direction of a new CON will continue to have significant impact on the health care delivery system and the residents in the greater Waterbury area and thus the State of Connecticut. It will continue to provide the benefit of accessibility to advanced cardiac services to which the greater Waterbury area has become accustomed and to which it has responded with considerable confidence. It will continue to provide necessary lifesaving and life changing services to greater Waterbury residents at a time when they need it most. This Program should not have a negative impact on the advanced cardiac programs throughout the state as current Program data shows that 90% of its patients originate from the 12 surrounding towns in the primary service area.

In addition, community outreach and education, a significant benefit of this Program, will continue to extend to the general public the knowledge necessary to modify risk factors and therefore to prevent heart disease. The function of community outreach and education is highly regarded and often requested by the surrounding communities. Through this service, free blood pressure, glucose and cholesterol screenings have been provided as well as educational series on signs and symptoms of heart disease and diabetes. Several hundred sessions for community groups, church groups, schools and businesses have been provided over the Program's three year existence servicing thousands of local community members.

7. Who will be responsible for providing the service?

Response: The greater Waterbury area is currently served by 18 local cardiologists. Interventional cardiologists include Stephen Widman, MD, Ehsan Ansari, MD, Raghuraman Vidhun, MD, Kevin Kett, MD and Suphichaya Muangman, MD. Connecticut Cardiothoracic Surgical Associates, a group of four cardiothoracic surgeons who also practice at Hartford Hospital and John Dempsey Hospital will continue to provide open heart surgery services. They include Paul Preissler, MD, Jonathan Hammond, MD, David Underhill, MD and Daniel Fusco, MD. Cardiac anesthesia is provided by Milford Anesthesia Associates which services the Program with four physicians including Paul Langevin, MD, David Heimbinder, MD, Ronald Burt, MD and Ricardo Cardenas, MD. Perfusion services are provided by John Dempsey Hospital. Saint Mary's Hospital and Waterbury Hospital currently employ all operating room nurses and technicians, catheterization lab nurses and technicians, cardiovascular unit nurses and ancillary staff. All staffing is currently in place.

8. Who are the current payers of this service and identify any anticipated payer changes when the proposed project becomes operational?

Response: The current payers for this service include commercial insurance companies as well as Medicare and Medicaid. There is no anticipated change in payer mix with the initiation of this replacement Program. All patients receive care regardless of their ability to pay.

Hartford, CT 06134

Dear Commissioner Vogel:

I am writing in strong support of the Heart Center of Greater Waterbury which is seeking a new Certificate of Need (CON) Order. This new CON is necessary because despite the overwhelming success of the Program, some of the target volume numbers have not met the specific criteria in the original CON.

Since July, 2005, the Heart Center of Greater Waterbury has successfully provided life saving cardiac procedures such as angioplasty and open heart surgery to residents of Waterbury and its surrounding communities. Many of the residents in my district depend upon this Center for critical procedures. The Center's unique approach to treating patients starts with education followed by diagnosis, treatment and finally rehabilitation. The physicians at the Center keep their patients informed during each step of the way and make every effort to treat any patient like a friend—not just a sick person. The presence of this facility in my area ensures that patients can receive quality care in a familiar setting, close to their home.

Thank you for your attention to this matter and please feel free to contact me with any questions.

Sincerely,

Arthur O'Neill

Commissioner Christine A. Vogel
Office of Health Care Access
410 Capitol Avenue
P.O. Box 340308
Hartford, CT 06134

Commissioner Christine A. Vogel:

Since July 2005, the Heart Center of Greater Waterbury has successfully provided life saving cardiac procedures such as open-heart surgery and angioplasty to residents of Waterbury and its surrounding communities, with the Town of Beacon Falls being one of those communities.

This program was approved by the Office of Health Care Access as a demonstration project with an expiration date of July 2008.

Despite the overwhelming success of the Program, some of the target numbers have not met the specific criteria in the Certificate of Need (CON) Order. Therefore, it is necessary for the Program to seek a new CON to assure that the greater Waterbury community continues to have access to these services locally. The Heart Center Board of Directors is working to finalize the strategy for the CON application.

As the First Selectman of the Town of Beacon Falls, I am urging you to consider a new Certificate of Need so that our residents have access to the services provided by the Heart Center of Greater Waterbury.

Thank you for your consideration

Sincerely,

Susan A. Cable

Dear Commissioner Vogel,

We are writing this letter in enthusiastic support of the Heart Center of Greater Waterbury's Certificate of Need (CON) order.

The program has provided Greater Waterbury residents with access to emergency cardiac care in a timely, efficient and competent manner which has saved lives. Both community hospitals have invested significant capital expenditures for equipment and structural renovations to ensure state of the art facilities for heart care. The Heart Center has successfully provided life saving cardiac procedures and open heart surgery to the residents of Waterbury and the surrounding communities. We believe the services that the Heart Center provides are vital to the health and well being of the residents in this region.

We respectfully request that you will continue your support of this vital program, and the opportunity it provides the Greater Waterbury population to access its lifesaving services locally.

Dear Commissioner:

Over the past three years I have witnessed first hand the success that was generated by the Heart Center subsequent to receiving a Certificate of Need from the State of Connecticut. Patients of Greater Waterbury and their families were served without the agony and expense of traveling out of town to receive medical attention.

Although the program failed to meet some of the criteria and conditions as stated in the original CON, I am a firm believer that the heart center is an asset to our community and that it fulfills a function that is desperately needed. Therefore, I am privileged to request your support for a new CON to ensure that those services performed by the Heart Center continue without interruption. Your consideration is very much appreciated.

June 30, 2008

Commissioner Cristine Vogel
Office of Health Care Access
410 Capitol Avenue
Hartford, CT 06106

Dear Commissioner Vogel:

I write today in unequivocal support of the Heart Center of Greater Waterbury's Certificate of Need (CON) order.

Simply put, the rationale for the CON, which I believe was undeniably demonstrated in 2005, remains the same. The Heart Center and the services it provides are absolutely vital to the health, safety and welfare of the residents of this region. Not only is the Center an essential lifeline to critical cardiac procedures in the Greater Waterbury area, but in my opinion, vital to the viability of its broader healthcare delivery system.

I am sure your office recognizes the great success of the program, the significant capital expenditures both community hospitals invested to ensure state of the art facilities to support it, and that over 2,400 local community residents have already benefited from its interventional procedures to date. I hope you will continue your support of this outstanding program, and the opportunity it provides the Greater Waterbury population to access its lifesaving services locally.

Please look to me if I can offer any further information, or assist in any way, as you review their new application.

Sincerely,

Kevin M. DelGobbo

Re: Letter of Intent, Docket Number 08-31202
Waterbury Hospital and St. Mary's Hospital (d/b/a Heart Center of Greater Waterbury) and John Dempsey Hospital
Establish a Primary and Elective Angioplasty and Open Heart Surgery Program at Waterbury Hospital and Saint Mary's Hospital
Notice of Letter of Intent

Dear Ms. Shea:

On July 8, 2008, the Office of Health Care Access ("OHCA") received the Letter of Intent ("LOI") Form of Waterbury Hospital and St. Mary's Hospital (d/b/a Heart Center of Greater Waterbury) and John Dempsey Hospital ("Applicants") to Establish a Primary and Elective Angioplasty and Open Heart Surgery Program at Waterbury Hospital and Saint Mary's Hospital.

A notice to the public regarding OHCA's receipt of a LOI was published in the *Waterbury Republican American* pursuant to Section 19a-638 of the Connecticut General Statutes. Enclosed for your information is a copy of the notice to the public.

Sincerely,

Kimberly R. Martone BD

RE: Certificate of Need Application Forms, Docket Number 08-31202-CON
The Waterbury Hospital and St. Mary's Hospital (d/b/a Heart Center of Greater Waterbury) and John Dempsey Hospital
Establish a Primary and Elective Angioplasty and Open Heart Surgery Programs at The Waterbury Hospital and St. Mary's Hospital

Dear Ms. Shea:

Enclosed are the application forms for The Waterbury Hospital and St. Mary's Hospital (d/b/a Heart Center of Greater Waterbury) and John Dempsey Hospital's Certificate of Need ("CON") proposal for the Establishment of Primary and Elective Angioplasty and Open Heart Surgery Programs at The Waterbury Hospital and St. Mary's Hospital with no associated capital expenditure. According to the parameters stated in Section 19a-638 of the Connecticut General Statutes the CON application may be filed between September 6, 2008, and November 5, 2008.

When submitting your CON application and any subsequent application information to this agency, you are obligated to observe the following procedural requirements. **Failure to observe these requirements will require follow-up work on your part to correct the filing.**

- Number and date each page, including cover letter and all attachments. Information filed after the initial CON application submission (i.e. completeness response letter, prefile testimony, late file submissions and the like) must be numbered sequentially from the Applicant's document immediately preceding it. For example, if the application concludes with page 100, your completeness response letter would begin with page 101.
- Submit one (1) original and eight (8) hard copies of each submission in **3-ring binders**.

- Submit a scanned copy of each submission in its entirety, including all attachments on CD, preferably in Adobe (.pdf) format.
- Submit an electronic copy of the documents in MS Word format with financial attachments and other data as appropriate in MS Excel format.

The analysts assigned to the CON application are Steven Lazarus and Alexis Fedorjaczenko. Please contact then at (860) 418-7001 if you have questions.

Sincerely,

Kimberly Martone
Certificate of Need Supervisor

Certificate of Need Application

Please complete all questions. If any question is not relevant to your project, Not Applicable will be an acceptable response. Your Certificate of Need application will be eligible for submission no earlier than September 6, 2008 and may be submitted no later than November 5, 2008. The Analysts assigned to your application are Steven W. Lazarus and Alexis G. Fedorjaczenko and they may be reached at the Office of Health Care Access at (860) 418-7012 and (860) 418-7067, respectively.

Docket Number: 08-31202-CON

Applicants Names: The Waterbury Hospital, St. Mary's Hospital and John Dempsey Hospital

Contact Person: Loraine Shea
Contact Title: Executive Director
Heart Center of Greater Waterbury
Contact Address: 1075 Chase Parkway
Waterbury, CT 06708

Project Location: Waterbury

Project Name: Establish Primary and Elective Angioplasty and Heart Surgery Surgery programs at The Waterbury Hospital and St. Mary's Hospital

Type proposal: Section 19a-638, C.G.S.

Est. Capital Expenditure: -0-

1. Contact Information

OHCA requires each Applicant to provide a separate contact person. Please complete the following "Contact Person" information for **each** Applicant:

Contact Information Required	*The Waterbury Hospital*	*St. Mary's Hospital*	*John Dempsey Hospital*
Name			
Title			
Phone & Fax Number			
Email Address			
Mailing Address			

2. Expansion of Existing or New Service

What services are currently offered at St. Mary's Hospital ("SMH") and The Waterbury Hospital ("TWH") that the proposed Elective and Primary Angioplasty and Open Heart Surgery services will augment or replace? Include any cardiovascular disease prevention and health promotion programs.

Augment: _____

_____

Replace: _____

_____

3. State Health Plan

No questions at this time.

4. Applicants' Long Range Plans

Is this application consistent with your long-range plan?

Yes ☐ No

If "No" is checked, please provide an explanation.

5. Clear Public Need

i. The record in this docket will include, in addition to other materials, the American College of Cardiology/American Heart Association (ACC/AHA) practice guidelines.

a. The Applicants may submit any comments in response to this evidence, which they deem appropriate.

b. Please discuss The Waterbury Hospital ("TWH") and St. Mary's Hospital ("SMH") d/b/a Heart Center of Greater Waterbury's ("HCGW") historical institutional and operator volumes (Elective and Primary Angioplasty and Open Heart Surgery) in relation to the ACC/AHA recommended volume guidelines.

ii. Explain how it was determined there was a need for the proposed interventional cardiac services at SMH and TWH.

iii. Provide the following information for **each** Applicant:

a) Primary and secondary service area towns specific to the proposed interventional cardiac services. Provide the methodology used to delineate the service areas.

b) Cardiovascular health statistics and risk factors in the service area. Provide evidence.

c) Please complete the following table for each of the Applicants' historical volume related to elective and primary angioplasty and open heart service ("OHS"), including John Dempsey Hospital ("JDH") since the operation of HCWG:

Table 1: *Historical* Volume for each Applicant (Institutional)

	FY 2005				FY 2006				FY 2007			
	A	B	C	D	A	B	C	D	A	B	C	D
TWH												
SMH												
HCGW Total												
JDH												

A: Primary Angioplasty. B: Elective Angioplasty, C: Open Heart Service & D: Cardiac Catheterizations
Please identify the procedure codes utilized for A, B, C & D.
Be sure that the volumes provided reconcile with the volumes listed in OHCA Hospital Reporting System, Schedule 450, the CT Office of Health Care Access's Inpatient Discharge Database and the CT Office of Health Care Access Cardiac Registry

d) Provide all assumptions and calculations utilized to project institutional volumes in Table I.

e) Please provide year-to-date volumes for FY 2008 by Applicant and Service as provided in Table 1. Be sure to include all assumption and calculations.

f) In the following table, provide the last three years of historical volume at HCGW for each Applicant by service and zip code:

Table 2: *Historical* Volume for each Applicant By Service and Zip Code

Applicant	Cardiac Service (i.e. A, B, C)	FY 2007 (# of Patients)	Zip Code	FY 2006 (# of Patients)	Zip Code	FY 2005 (# of Patients)	Zip Code
TWH	A						
	B						
	C						
SMH	A						
	B						
	C						
JDH	A						
	B						
	C						

Note: A: Primary Angioplasty. B: Elective Angioplasty, & C: Open Heart Service

g) In a table format, please provide last three years of cardiac catheterization volume (by facility) by inpatient and outpatient and by zip code.

Table 3: *Historical* Cardiac Cath Volume for each Applicant by Service and Zip Code

Applicant	FY 2007 (Total # of Patients)	I/P	O/P	Zip Code	FY 2006 (Total # of Patients)	I/P	O/P	Zip Code	FY 2005 (Total # of Patients)	I/P	O/P	Zip Code
TWH												
SMH												
JDH												

Key: Inpatient= I/P, Outpatient= O/P
Be sure that the volumes provided reconcile with the volumes listed in OHCA Hospital Reporting System, Schedule 450, the CT Office of Health Care Access's Inpatient Discharge Database and the CT Office of Health Care Access Cardiac Registry

iv. Please provide year-to-date volumes for FY 2008 by Applicant and Service as provided in Tables 2 & 3. Be sure to include all assumption and calculations.

v. In the following table provide the number of patients that were transferred between the Applicants during FYs 2005, 2006, 2007, and year-to-date FY 2008 related to interventional cardiac services. Be sure to cite the reasons as well.

Table 4: *Historical* Patient Transfer between the Applicants

FY	FY 2008 (Y-T-D)	FY 2007	FY 2006	FY 2005	List reasons for transfer
JDH to SMH					
JDH to TWH					
SMH to JDH					
TWH to JDH					
SMH to TWH					
TWH to SMH					

vi. Provide the following for the projected utilization of the proposed service for each Applicant:

Table 5: *Projected* Volume for each Applicant (Institutional)

	FY 2009				FY 2010				FY 2011			
	A	B	C	D	A	B	C	D	A	B	C	D
TWH												
SMH												
HCGW Total												
JDH												

A: Primary Angioplasty. B: Elective Angioplasty, C: Open Heart Service & D: Cardiac Catheterizations
Please identify the procedure codes utilized for A, B, C & D.

h) Provide all assumptions and calculations utilized to project institutional volumes in Table 5.

i) In the following table format, please provide the projected first three years of cardiac catheterization volume (by facility) by inpatient and outpatient:

Table 6: *Projected* Cardiac Cath. Volume for Each Applicant

Applicant	FY 2009 (# of Patients)	I/P	O/P	FY 2010 (# of Patients)	I/P	O/P	FY 2011 (# of Patients)	I/P	O/P
TWH									
SMH									
JDH									

Key: Inpatient= I/P, Outpatient= O/P

j) Provide all assumptions and calculations utilized to project institutional volumes in Table 6.

k) Provide the historical operator volume by unique physician identifier currently providing services at each Applicant's facility as follows:

Table 7: *Historical* Operator Volume for each Applicant

Physician	By Facility	FY 2007				FY 2006				FY 2005			
		A	B	C	D	A	B	C	D	A	B	C	D
Physician A	TWH												
	SMH												
	JDH												
Physician B	TWH												
	SMH												
	JDH												

A: Primary Angioplasty. B: Elective Angioplasty, C: Open Heart Service & D: Cardiac Catheterizations
Please identify the procedure codes utilized for A, B, C & D.

l) Please provide year-to-date volumes for FY 2008 by Operator and by Facility and Service as provided in Table 7. Be sure to include all assumption and calculations

m) Provide the projected operator volume by unique physician identifier currently providing services at each Applicants' facility as follows:

Table 8: *Projected* Operator Volume for each Applicant

Physician	By Facility	FY 2009				FY 2010				FY 2011			
		A	B	C	D	A	B	C	D	A	B	C	D

A: Primary Angioplasty. B: Elective Angioplasty, C: Open Heart Service & D: Cardiac Catheterizations
Please identify the procedure codes utilized for A, B, C & D.
Be sure to provide 3 full years of projections.

n) Provide all assumptions and calculations utilized to project operator volumes in Table 8.

o) In the following table format, please provide last three years of cardiac catheterization volume by inpatient and outpatient, by operator and facility.

Table 9: *Projected* Cardiac Cath. Volume by Operator

Physician	Facility	FY 2009 (# of Patients)	I/P	O/P	FY 2010 (# of Patients)	I/P	O/P	FY 2011 (# of Patients)	I/P	O/P

Key: Inpatient= I/P, Outpatient= O/P

p) Provide all assumptions and calculations utilized to project operator volume by facility in Table 9.

B. Please address the following questions regarding the existing providers:

a. Identify the existing providers of interventional cardiac services that will be affected by this proposal.

b. Please explain how these aforementioned providers of interventional cardiac services will be affected by your proposal (i.e. patient volume, quality of care, etc.).

c. Discuss in detail the impact HCGW has had on these providers (i.e. volume, quality of care, etc.) over the past three years HCGW has been in operation.

C. Will your proposal remedy any of the following barriers to access? Please provide an explanation.

☐ Cultural ☐ Transportation

☐ Geographic ☐ Economic

☐ None of the above ☐ Other (Identify) _____

If you checked other than None of the above, please provide an explanation.

D. Have the Applicants conducted a Needs Assessment and a Market Share Analysis for the proposed cardiac services?

a. If the response is No, please explain in detail why not and what did the Applicants utilize to assess the need for this proposal?

b. If yes, explain in detail what Needs Assessment and Market Share Analysis were conducted, the process and the results.

c. Provide a copy of the Needs Assessment and the Market Share Analysis conducted by the Applicants.

E. Provide copies of any of the following plans, studies or reports related to your proposal:

☐ Epidemiological studies ☐ Public information reports

☐ Other (Identify) _____

6. Quality Measures

A. Check off all the Standard of Practice Guidelines that will be utilized by the Applicants for the proposed services. Please submit the most recent copy of each report related to the proposal:

☐ American College of Cardiology	☐ National Committee for Quality Assurance	☐ Public Health Code & Federal Corollary
☐ National Association of Child Bearing Centers	☐ American College of Obstetricians & Gynecologists	☐ American College of Surgeons
☐ Report of the Inter-Council for Radiation Oncology	☐ American College of Radiology	☐ Other: Specify _____

B. Explain how the Applicants plan to meet the American College of Cardiology/American Heart Association practice guidelines related to this proposal. If the Applicants do not expect the proposed interventional cardiac program to meet these guidelines and protocols, please explain how quality of the interventional cardiac programs will be maintained in relation to the ACC/AHA guidelines.

C. Submit a list of all key professional and administrative personnel, including the Chief Executive Officer (CEO) and Chief Financial Officer (CFO), Medical Director of Interventional Cardiac Program, Cardiac Surgeons, Interventional Cardiologists, etc. related to the proposal and a copy of their Curriculum Vitae.

Note: For physicians, please provide a list of hospitals where the physicians have admitting privileges.

D. Provide a copy of the most recent inspection reports and/or certificate for each facility:

☐ DPH	☐ JCAHO
☐ Fire Marshall Report	☐ AAAHC
☐ AAAASF	☐ Other: _____

Note: Above referenced acronyms are defined below. [1]

[1] DPH – Department of Public Health; JCAHO – Joint Commission on Accreditation of Hospitals Organization; AAAHC – Accreditation Association for Ambulatory Health Care, AAAASF – American Association for Ambulatory Surgery Facilities, Inc.

E. Provide a copy of the following (as applicable):

☐ A copy of the related Quality Assurance plan

☐ Protocols for service

☐ Patient Selection Criteria/Intake form

7. Improvements to Productivity and Containment of Costs

In the past year have your facilities undertaken any of the following activities to improve productivity and contain costs?

☐ Energy conservation ☐ Group purchasing

☐ Reengineering ☐ None of the above

☐ Application of technology (e.g., computer systems, robotics, telecommunication systems, etc.)

☐ Other (identify)_____

8. Miscellaneous

A. Will this proposal result in new (or a change to) your teaching or research responsibilities?

☐ Yes ☐ No

If you checked "Yes," please provide an explanation.

B. Are there any characteristics of your patient/physician mix that makes your proposal unique?

☐ Yes ☐ No

If you checked "Yes," please provide an explanation.

9. Affiliation

a. Provide a copy of the agreement TWH and SMH have drafted or signed with JDH to act as a tertiary care hospital to the proposed cardiac services.

b. Provide a copy of any and all agreements between the Applicants, including a signed collaboration agreement, related to the proposal. The collaboration agreement should include at a minimum a description of each Applicant's responsibilities, patient selection guidelines, provision of emergency transfers, joint quality assurance reviews and joint training.

c. Provide a detailed discussion on what role has JDH played in HCGW operation beyond the initial training of the staff and establishment of the protocols.

d. Discuss in detail the responsibilities of JDH in the establishment of the proposed services at TWH and SMH and the operation of HCGW.

e. Provide Board of Directors or governing body resolutions from **each** Applicant approving the proposal.

10. Financial Information

a. Type of ownership: (Please check off all that apply)

☐	Corporation (Inc.)	☐	Limited Liability Company (LLC)
☐	Partnership	☐	Professional Corporation (PC)
☐	Joint Venture	☐	Other (Specify): _____

b. Provide the following financial information:

i) Please confirm that each of the Applicants involved in this proposal has filed its FY 2007, audited financial statements with OHCA, as required pursuant to Section 19a-644, C.G.S.

ii) Provide the cash equivalent balance of each Applicant at the date of submission of this application.

iii) Provide a copy of the most recently completed internal monthly financial statement for each Applicant.

11. Revenue, Expense and Volume Projections

a. Payer Mix Projection

Please provide both the current payer mix and the projected payer mix with the CON proposal for the Total Facility based on Gross Patient Revenue in the following reporting format for **SMH**, **TWH**, **HCGW** and **JDH**, separately:

Total Facility Description	Current Payer Mix	FY 2009 Projected Payer Mix	FY 2010 Projected Payer Mix	FY 2011 Projected Payer Mix
Medicare*				
Medicaid* (includes other medical assistance)				
TriCare (CHAMPUS)				
Total Government Payers				
Commercial Insurers*				
Self-Pay				
Workers Compensation				
Total Non-Government Payers				
Uncompensated Care				
Total Payer Mix	100.0%	100.0%	100.0%	100.0%

*Includes managed care activity.

b. Provide the following for **SMH**, **TWH**, **HCGW** , **JDH** and the **parent corporations**, regarding the financial projections:

i) A summary of revenue, expense and volume statistics, with the CON project, without the CON project and incremental to the CON project. **See attached.**

ii) As an addendum to your completed financial attachments as provided in 11b(1), for **each** Applicant (by facility and total system) provide a break out of the financial expenses and revenues by service (i.e. Primary Angioplasty, Elective Angioplasty and Open Heart Surgery).

iii) The assumptions utilized in developing the projections (e.g., FTE's, volume statistics, other expenses, revenue and expense % increases, project implementation date, etc.).

iv) Provide a description of the additional staff, equipment, and supplies (including drug-eluting stents) required to provide the proposed services. Include a description of the availability of cardiac interventionalists, cardiac surgeons, nurses and anesthesiologists.

v) An explanation for any incremental losses (Historical and Projected) by service (i.e. Primary Angioplasty, Elective Angioplasty and Open Heart Service).

vi) Please complete the enclosed, OHCA's **Financial Attachment II,** for SMH, TWH, and JDH.

13.C(x). Please provide three years of projections of incremental revenue, expense and volume statistics **attributable to the proposal** in the following reporting format:

Type of Service Description	CT Services
Type of Unit Description:	CT Scan
# of Months in Operation	3

Year 1 **FY Projected Incremental** Total Incremental Expenses:	(1) **$53,513**	(2) Rate	(3) Units	(4) Gross Revenue Col. 2 * Col. 3	(5) Allowances/ Deductions	(6) Charity Care	(7) Bad Debt	(8) Net Revenue Col.4 - Col.5 -Col.6 - Col.7	(9) Operating Expenses Col. 1 Total * Col. 4 / Col. 4 Total	(10) Gain/(Loss) from Operations Col. 8 - Col. 9
Total Facility by Payer Category:										
Medicare		$1,000	42	$42,000	$28,467	$0	$0	$13,533	$17,838	($4,305)
Medicaid		$1,000	3	$3,000	$1,963	$0	$0	$1,037	$1,274	($237)
CHAMPUS/TriCare		$1,000	0	$0	$0	$0	$0	$0	$0	$0
Total Governmental		$1,000	45	$45,000	$30,430	$0	$0	$14,570	$19,112	($4,542)
Commericial Insurers		$1,000	79	$79,000	$42,229	$2,000	$0	$34,771	$33,552	$1,219
Uninsured		$1,000	2	$2,000	$900	$1,050	$0	$50	$849	($799)

To: 'Loraine Shea (HCGW)'
Subject: RE: Docket No.: 08-31202, CON Application Forms

Loraine,

I mistyped, I do meant the Table 9, should be "Projected" Cardiac Cath. Volume by Operator as titled on the table itself. The question leading to is misstated (question "o") and should ask for three years projected.

Hopefully that answers your question.

Steven,
I was inquiring about table 9 (below) and these answers refer to table 8. could you review again?

Subject: RE: Docket No.: 08-31202, CON Application Forms

Hi Loraine,

I reviewed our CON Application forms that were sent out and in Questions vi) m, Table 8, OHCA is requesting the "Projected Operator Volume for each Facility." The wording in the written question m should state "projected" not "historical." In the question and the table prior this question (vi)k, we are requesting the "Historical" Operator volume for each Applicant.

So to clarify the Table 8 is correct and the question leading to Table 8 should have requested "projected" volume not "historical" volume.

Please let me know you have require any further clarification and sorry for the confusion.

Steven,
Thank you for forwarding these documents. In reveiw of the application I have one question.

Page 6 or 12 of the application: (at the bottom) It appears to ask for historical volume however the table is referring to projected volume. Could you clarify that for me? (I have cut and pasted from the application)

o) In the following table format, please provide last three years of cardiac catheterization volume by inpatient and outpatient, by operator and facility.

Table 9: *Projected* Cardiac Cath. Volume by Operator

Physician	Facility	FY 2009 (# of Patients)	I/P	O/P	FY 2010 (# of Patients)	I/P	O/P	FY 2011 (# of Patients)	I/P	O/P

Key: Inpatient= I/P, Outpatient= O/P

thanks very much

Applicants Names: The Waterbury Hospital, Saint Mary's Hospital and John Dempsey Hospital

Contact Person: Loraine Shea
Contact Title: Executive Director
Heart Center of Greater Waterbury
Contact Address: 1075 Chase Parkway
Waterbury, CT 06708

Project Location: Waterbury

Project Name: Replace Demonstration Primary and Elective Angioplasty and Open Heart Surgery Program at The Waterbury Hospital and Saint Mary's Hospital with a Permanent Primary and Elective Angioplasty and Open Heart Surgery Program at The Waterbury Hospital and Saint Mary's Hospital

Type proposal: Section 19a-638, C.G.S.

Est. Capital Expenditure: -0-

Executive Summary

Our case for the Office of Health Care Access's granting of permanent status to the Heart Center of Greater Waterbury, as it is currently configured, rests on four pillars:

I. Community access to life-saving services for a large population.
II. A program configuration that provides a practical, working solution for the Greater Waterbury community at this time while optimizing the use of institutional resources and respecting patient choice.
III. Proven success of the demonstration project.
IV. The current, and still evolving, standard of care for patients with heart disease.

Access to life-saving services:

The Heart Center of Greater Waterbury has had an extraordinary impact on our community by correcting what was once a flawed delivery system for cardiac care. The Office of Health Care Access took an affirmative step when it granted approval for the original demonstration project. No longer does the Waterbury area suffer from being the only major region in Connecticut without a full service, comprehensive cardiac program.

Because the direct connection between rapid intervention and subsequent outcome is incontrovertible, it is no longer morally acceptable that such a large population concentration be deprived of rapid and consistent access to these life-saving interventions. There is ample evidence that a return to the pre-demonstration project "drip and ship" process would certainly result in deaths and disability due to heart muscle damage that could have been prevented. Local availability of full cardiac services also benefits patients by keeping them close to the support of family and friends as well as other professional caregivers. It is also clear that the success of the Heart Center of Greater Waterbury has irrevocably changed the standard of heart disease care in our region to such an extent that loss of the program would precipitate the unraveling of an entire system of care on which thousands of area residents depend.

A configuration that works:

The two Waterbury hospitals are proud of their history of collaboration on complex clinical services. Ours is a working relationship that can serve as a model for other Connecticut communities. The two hospitals continue to work toward bringing that collaboration to its logical conclusion: a full merger.

Each of our collaborations – the Harold Leever Regional Cancer Center, the Heart Center of Greater Waterbury, and, most recently, the consolidation of inpatient pediatrics in partnership with the Connecticut Children's Medical Center- - has been configured differently, depending on community needs, available

capital and facilities resources, hospital utilization patterns (particularly Emergency Department use patterns), transportation patterns, and so forth. The advanced cardiac program ensures quality outcomes through its completely common elements: patient care protocols developed with John Dempsey Hospital; the surgical team (surgeons, perfusionists) also provided under contract with John Dempsey Hospital; cardiac anesthesiologists; interventional and medical cardiologists; participation in national quality of care databases and a quality oversight program with participation from John Dempsey Hospital. According to the latest literature, individual surgeon's volume is the key quality variable for open heart surgery, and our surgeons and interventional cardiologists are among the busiest in Connecticut.

The demographics and economic vitality of the core towns of our region are matters of great concern to us, and it is no secret that both hospitals are financially stressed. Access to capital for equipment and facilities is a particularly difficult issue. Our hospitals are constantly challenged to find creative and pragmatic solutions to our diverse community's health care needs. We believe that The Heart Center of Greater Waterbury represents just such a practical solution that has been demonstrably successful, not only in saving lives, but in achieving high quality outcomes.

In considering our application, we hope that the Office of Health Care Access will give appropriate weight to the work of those who know and understand the unique characteristics of our community and the patient population we serve. We also firmly believe that the Office of Health Care Access should not attempt to force further consolidation of this program—with the attendant disruptions and capital costs – unnecessary costs that neither financially distressed Waterbury hospital can afford. Any further consolidation should occur only within the context of a broader institutional integration plan.

A successful demonstration project:

By a host of measures, the Heart Center of Greater Waterbury has met or exceeded expectations.

- Angioplasty volumes that exceeded demonstration project volume targets by 50%
- Exemplary door-to-balloon times that boast a time-to-treatment that is better than the national benchmark
- Excellent angioplasty and open heart surgery outcomes, as measured by our participation in national databases
- Open heart surgery services provided by one of Connecticut's busiest cardiothoracic surgical practices, at volume levels that have proven quality performance can and does exist at the community hospital level
- Outstanding patient satisfaction in the cardiovascular intensive care units
- Robust community programs providing free health education to residents

We believe that the Waterbury program was, in fact, held to a much higher standard than that applied to both established programs and other recently approved programs. We hope that the standard of judgment for the approval of a permanent program will be based on the realities of the greater Waterbury region, and thoughtfully applied.

Standard of care:

In an urban area such as greater Waterbury, with a large population of poor and elderly citizens who are often medically fragile, and who cannot travel easily to other cities for acute care, the lack of a full service cardiac program is simply no longer acceptable. Interventional cardiac services – angioplasty and open-heart surgery – are the centerpiece of an entire system of care that includes preventive medicine and medical therapies as well as these more invasive, acute forms of care, and thus benefits thousands of greater Waterbury residents, not just the acutely ill. We also expect that the best treatments for the various manifestations of heart disease will continue to evolve. The continuation of a full service program in Waterbury ensures that all current treatment options are at the disposal of our local caregivers and available to our citizens, and, at the same time, will enable our program to evolve along with changing technologies.

In conclusion, while we believe that community access to life-saving services is the critical issue in this case, not hospital finances, it is also clear that the positive financial impact on the two Waterbury hospitals has been significant and is an important consideration in the potential merger of the two organizations. As the Office of Health Care Access evaluates our application, we hope that the agency will take the above factors into account, each on its own merits, but also recognize that these elements are completely intertwined. The question of "sufficient utilization" should be analyzed and evaluated in terms of the overall community impact, taking into account all the procedures provided by the overall program, not merely open heart surgery procedures.

Together we have the opportunity to ensure that the appropriate standard of health care is accessible to the residents of greater Waterbury. It is our mandate as health care professionals to provide essential life saving services where the need is so clearly warranted

1. Contact Information

OHCA requires each Applicant to provide a separate contact person. Please complete the following "Contact Person" information for **each** Applicant:

Contact Information Required	*The Waterbury Hospital*	*Saint Mary's Hospital*	*John Dempsey Hospital*

2. Expansion of Existing or New Service

What services are currently offered at St. Mary's Hospital ("SMH") and The Waterbury Hospital ("TWH") that the proposed Elective and Primary Angioplasty and Open Heart Surgery services will augment or replace? Include any cardiovascular disease prevention and health promotion programs.

Response:

Replace: Saint Mary's Hospital (SMH) and The Waterbury Hospital (TWH) d/b/a the Heart Center of Greater Waterbury (HCGW) have a longstanding history of providing cardiac services to patients of the greater Waterbury area. These services include inpatient and outpatient cardiology and medical services as well as timely emergency room care. Over the last three years the HCGW has had a proficient and active angioplasty and open heart surgery demonstration project that has been available for over 270,000 people in the Waterbury region, and directly serviced more than 2,400 patients, all while maintaining excellent outcomes.

Non-Invasive Cardiology:

- EKG testing with extensive database of historic EKG tests
- Holter monitor testing
- Echocardiography including Trans Esophageal Echocardiography with extensive database of historic tests
- Stress Testing (treadmill, pharmacologic)
- Cardiology dedicated dual head nuclear cameras

Invasive Cardiology:

- Diagnostic Cardiac Catheterizations
- Single room with Biplane imaging
- Intra-aortic balloon pump placement
- Implants Pacemaker
- Implants Defibrillators

Cardiology Clinics:

- Pacemaker Clinic

Cardiac Rehab:

- Phase I
- Phase II
- Phase III

Peripheral Vascular:

- Interventional and diagnostic procedures
- Minimally Invasive Abdominal Aneurysm Endovascular procedures
- CT/MRI angiography
- Endovascular and traditional open vascular surgery
- Peripheral angioplasty

Critical Care Units:

- Critical care units directed by Board Certified Intensivists
- Cardiovascular unit--one stop post operative model for interventional cardiology patients
- Ongoing nursing education in collaboration with Advanced Practice Nurses
- High percentage of RN with CCRN certification
- Telemetry and hemodynamic units available
- 24 hour physician unit, coverage provided by on-site surgical and medical residency program

Emergency Department:

- Cardiac care protocols in place
- Cardiac monitors available in treatment rooms

Other:

- CT calcium scoring
- Computerized tomography angiography

Advanced Cardiac Services:

- Elective angioplasty
- Primary angioplasty
- Open heart surgery

In addition, HCGW offers an extensive community outreach and education program which is provided to the greater Waterbury community as a free service. Community outreach activities include heart health education on the signs and symptoms of heart disease, risk factors and prevention, a cardiac support group, free screenings for blood pressure and cholesterol and smoking cessation classes provided in collaboration with the American Lung Association. Over the last three years thousands of greater Waterbury residents have benefited from the ongoing education and outreach provided by the Program's Advanced Practice Registered Nurse and physicians (See Appendix 2).

SMH and TWH have an active and attending medical staff of 325 and 432, respectively. In a community with two hospitals there is overlap of medical staff; however both hospitals have an excellent physician base representing all major specialty areas. Of those, there are 17 cardiologists including 5 interventional cardiologists, 4 cardiothoracic surgeons and 4 cardiac anesthesiologists actively practicing at both hospitals. HCGW patients benefit from the same team of physicians regardless of which campus they choose for care.

It is the intention of the Applicants to replace the highly successful advanced cardiac services noted above with a permanent Program offering continued high quality and service excellence under the direction of this new Certificate of Need (CON). The greater Waterbury area is relying on HCGW, in conjunction with John Dempsey Hospital (JDH), to continue to provide these lifesaving services close to home.

Since July 18, 2005, the HCGW, in conjunction with JDH, has substantially improved the quality of medicine and, in particular, cardiac care by successfully providing advanced cardiac services. Thousands of residents have experienced and come to rely upon the current standard of care for comprehensive cardiac services, over 2,400 of which have received

interventional care. A permanent cardiac Program will provide a comprehensive chain of care that begins with diagnosis, continues through all levels of necessary treatment and completes itself with rehabilitation, community education and prevention that will serve to augment existing vital cardiac services. The chain must not be broken by removing the "treatment" link.

3. State Health Plan

No questions at this time.

4. Applicants' Long Range Plans

Is this application consistent with your long-range plan?

Yes ☒ ☐ No

If "No" is checked, please provide an explanation.

Response:

The long range plans of SMH and TWH include a shared vision to build upon a history of successful collaboration to create a health care delivery system that will ensure sustainable access to quality health care for our community. The Board of Directors and executive management teams at each hospital see the continuation of the HCGW on a permanent basis as imperative to achieving this vision. The HCGW is just one example of successful collaborations between the institutions. The hospitals also enjoy shared endeavors in oncology, PET/CT imaging, inpatient pediatrics and the Waterbury Health Access Program (WHAP). In fact, the collaborative relationship between SMH and TWH is a model that other Connecticut cities with two hospitals should seek to emulate.

As stated above, the Applicant's proposal is consistent with their vision and plans for the future. However, one must also look at history and what greater Waterbury has achieved in terms of advanced cardiac care for its citizens. Just a few years ago SMH and TWH embarked on what was then a strategic plan to correct a flawed delivery system for cardiac care in the greater Waterbury area. The result has been to provide greater Waterbury residents with access to emergency and elective cardiac services in a timely, efficient and competent manner. It is well known to the Office of Health Care Access that SMH and TWH are financially distressed hospitals operating in a challenging environment. When the Program was designed, it was done in a way that made the most cost effective use possible of the two existing campuses. Where new infrastructure needed to be developed it was done so with the philosophy of being One Program. The hospitals initially invested approximately $7 million. Today this single Program has identical catheterization labs, operating room suites and cardiovascular intensive care unit models. It also has identical care-giving teams of cardiologists, interventional cardiologists, cardiothoracic surgeons, cardiac anesthesiologists and perfusionists. The Program works exceedingly well in the context of our existing health care delivery system including, most importantly, hospital use patterns. It is a model that should not be modified simply because it is different from other programs in Connecticut. Residents of other Connecticut urban areas have two hospitals with separate and distinct advanced cardiac Program offerings. How fortunate for the residents of greater Waterbury, the fourth largest urban area in the State, that their hospitals had the foresight to be collaborative in the development of one advanced cardiac care Program. A Program that not only has saved lives, but has provided continuity of care regardless of which side of the Naugatuck River one chooses to receive treatment. What was once a long range plan for advance cardiac services has been successfully implemented and should be allowed to continue on a permanent basis.

As mentioned above, when the Program was designed it was done in a way that made the most effective use possible of the two existing hospital campuses. A great deal of thought and consideration went into the original design of the Program. If the Applicants were asked if the same infrastructure and design choices would be made again, and if we knew then what we know now, the answer would be a resounding "yes". In the development of the Program, serious consideration was given to alternatives that were evaluated against various criteria including the community uniqueness, long range plans and collective experience. As a point of reference, the Program alternatives explored are outlined below.

- Primary angioplasty (only) in Waterbury
- Full service advanced cardiac care in Waterbury – jointly managed, one campus
- Full service advanced cardiac care in Waterbury – jointly managed, two campuses

Primary angioplasty (only) in Waterbury:

While a primary angioplasty only (PAMI-only) program may be solution for other communities, it is not so for the fourth largest urban region in the State. PAMI-only programs offer services to only a small segment of the total population requiring immediate emergency interventional cardiac care. Given the volume of patients seen in Waterbury, the Program would find itself in an untenable situation whereby a patient could present with STEMI (ST- Elevation Myocardial Infarction) and be treated with primary angioplasty intervention, while, simultaneously, another patient presents with unstable coronary syndrome, undergoes a cardiac catheterization which identifies the need for coronary intervention, and must subsequently be transferred to another location for definitive therapy. The cardiologist and clinical staff involved in this scenario could have treated both patients in one locale, providing the most efficacious treatment, while saving time and dollars. Moreover, under a PAMI-only program, current caregivers, having provided a full range of life-saving angioplasty services over the last three years during the demonstration project, would find themselves in the untenable situation of not being able to practice what they have demonstrated an ability to do exceedingly well. A step backward in the standard of care would be an unfortunate and devastating result.

Furthermore, PAMI-only programs often produce a financial loss. Although some hospitals are able to absorb this loss, the case is quite different with SMH and TWH. The financial burden for physician coverage and staffing could not be offset by the other cardiac services. This additional financial burden that would be incurred would further distress the overall status of both SMH and TWH, and impact the ability of each campus to operate other unprofitable medical, surgical and psychiatric clinics that are so desperately needed by the poor and uninsured in this region.

Full service advanced cardiac care in Waterbury – jointly managed, one campus:

Patients receiving care at either of the Program's campuses benefit from the care of established, experienced interventional cardiologists, cardiothoracic surgeons and clinicians. Patients suffering chest pain, or other symptoms associated with a heart attack, are well advised to go to the nearest emergency department for expert evaluation. While such symptoms may or may not be due to a heart attack, patients who think they may be having a

heart attack would choose the emergency department in Waterbury where both coronary intervention and open heart surgery capabilities exist. Likewise, patients seeking diagnostic treatment and in need of a cardiac catheterization would choose the location where therapeutic care is co-located and open heart surgery is available if needed. According to the Connecticut Hospital Association's *Patient Census Report*, the combined total of emergency department visits at both of the Waterbury hospitals was almost 122,400 in fiscal year 2007. The emergency departments, catheterization labs, cardiovascular intensive care units and telemetry units at SMH or TWH campuses could not accommodate such a shift in demand. To consolidate services to a single campus would cost more, in terms of capital investment, than the two campus model, because one institution's facilities would have to be expanded in order to meet forecasted demand, while the other institutions facilities would suffer from diminished use—resulting in an unnecessary waste of existing resources.

Full service advanced cardiac care in Waterbury – jointly managed, two campuses:

Having carefully considered other options, we are convinced that the Program as currently designed, with care provided at both campuses, is the most practical and cost effective way to provide advanced, comprehensive cardiac care services to the citizens of greater Waterbury. Our proposal takes advantage of existing facilities and medical expertise, and meets or exceeds all of the quality standards of regulatory and professional bodies. The local affiliation is greatly enhanced by an innovative partnership with JDH, opening new opportunities for medical education, research and further regional collaboration.

SMH and TWH, are in the best position to determine what will work best for the hospitals, medical community and residents of greater Waterbury.

Consolidation scenario after a potential merger:

It is important to address the effect of a potential merger of SMH and TWH on the provision of advanced cardiac services. It is well known that the demand for patient care is such that both hospital campuses would need to be fully utilized for several years post merger. A newly built hospital, while ideal, may not be financially possible for many years and it may not be the best approach in the foreseeable future. As such, the first step would be to launch the planning for numerous integration and transition tasks, while maintaining operations. Complex services or services that are already producing positive results such as advanced cardiac care may not be restructured for several years. Reference: Implementation timeline excerpt from the March 2008 presentation by SMH and TWH to Commissioners of State agencies (Appendix 4). The cardiac program would, by necessity, likely continue to operate in its current two campus formation for several years after the signing of final merger documents.

It is in the public record that the leadership of SMH and TWH are working towards a full asset merger of their hospitals for the benefit of health care in the region. There is full commitment from all parties to make it happen in the near future.

Future leadership will most certainly review the provision of advanced cardiac services to consider if a re-configuration of these services would bring definitive value to the citizenry, cardiologists, surgeons and institution. The analysis will be quite complex as the impact of

such a consolidation of services would impact emergency, trauma, laboratory and blood bank services, physical space such as dedicated operating rooms, cardiac catheterization laboratories, inpatient telemetry and cardiovascular unit beds, cardiac rehabilitation services and numerous other areas.

However, if restructuring the provision of advanced cardiac services would bring significant benefit to the merged institution and render benefit to the public, and if there is adequate capital available to fund such a large restructuring of facilities; the merged hospital would take steps to bring that benefit to the region in due course.

5. Clear Public Need

i. The record in this docket will include, in addition to other materials, the American College of Cardiology/American Heart Association (ACC/AHA) practice guidelines.

a. The Applicants may submit any comments in response to this evidence, which they deem appropriate.

Response:
American College of Cardiology/American Heart Association (ACC/AHA):

The Applicants submit the following comments regarding the ACC/AHA practice guidelines. The ACC/AHA has produced volumes of guidelines, clinical competence statements and practice guidelines. For the purpose of this discussion, several documents from ACC/AHA are referenced with their title and date. The ACC/AHA published a revised Guideline Update for Coronary Artery Bypass Graph Surgery (CABG) in 2004. The revised guidelines were approved by the American College of Cardiology Foundation Board of Trustees in March 2004 and by the American Heart Association Science Advisory and Coordinating Committee in June 2004 and published for the first time on August 31, 2004 in *Circulation Journal of the American Heart Association*. These guidelines are not the same guidelines considered when the Program's demonstration project was approved in July 2004 and, therefore, serious consideration should be given to the revisions. *Section 7 Institutional and Operator Competence, 7.1 Volume Considerations* (Appendix 5.i.a) provides an extensive review of relevant literature that the Applicants request OHCA to consider. The studies found that a wide variation in mortality rates exists and that some low volume programs maintained excellent outcomes which call into question the use of volume as a sole proxy for quality. The conclusion reached is as follows:

> ...In summary, studies suggest that survival after CABG is negatively affected when carried out in institutions that perform less than a threshold number of cases annually. Similar conclusions have been drawn regarding individual surgeon volumes. In states where reporting of outcomes is an accepted practice (e.g., New York State), the relationship between low volumes at either an institutional or individual level seems to have diminished over time. This observation strengthens the argument for outcome tracking and supports a posture of close monitoring of institutions or individuals that perform less than 100 cases annually. It must be remembered that these same studies also found a wide variation in risk-adjusted mortality rates in low volume situations; i.e. some institutions and practitioners maintained excellent outcomes despite relatively low volumes. Therefore, credentialing policies based on conclusions drawn from these data must be made with caution....

The above referenced Guideline Update for CABG Surgery continues to support the argument for monitoring clinical outcomes in those programs that perform less than 100 surgical cases annually. The guidelines certainly do not support the position that an existing quality program with an institutional volume of less than 100 surgical cases not

be allowed to operate. As a Program, HCGW has always performed above 100 cases and, as demonstrated later in the application, is projected to do so in the future. These guidelines refer to surgeon volume as well which, in the case of this Program, is an important factor as seen in the response to question 5.i.b.

As the ACC/AHA guidelines refer to the provision of primary and elective angioplasty services, the Applicants have continuously reviewed the ACCF/AHA/SCAI 2007 Update of The Clinical Competence Statement on Cardiac Interventional Procedures, an update of the 1998 Clinical Competence Statement, published June 25, 2007 in *Circulation* (Appendix 5.i.a).

The Program has met and adhered to the Clinical Competence Statement as it applies to institutional system requirements and will continue to do so. The guideline states:

> ...The interventional laboratory must have an extensive support system of specifically trained laboratory personnel. Cardiothoracic surgical, respiratory, and anesthesia services should be available to respond to emergency situations in order to minimize detrimental outcomes. The institution should have systems for credentialing, governance, data gathering, and quality assessment. Prospective, unbiased collection of key data elements on consecutive patients and consistent feedback of results to providers brings important quality control to the entire interventional program. The ACC/AHA/SCAI 2005 Guideline Update for angioplasty recommends that each interventional program performing elective angioplasty should have in-house surgical support. Institutions that do not have in-house surgical support and are performing primary open surgery only for STEMI, should have an established, well-organized system for emergency transfer to surgery at another institution....

This updated Clinical Competence Statement also speaks to the operator volume issue and although the recommended volumes have not changed from 75 procedures per operator, it is critical to this process to understand the scientific review behind the recommendations. The Clinical Competence Statement states:

> ...it is also important to underscore that there are significant limitations to the simplistic interpretation of procedure volume statistics as a measure of competence and quality. First, it is uncertain whether this relationship is a result of the "practice makes perfect" principle, or the fact that patients are more frequently referred to high-quality operators. Second, it remains unclear where the "cut-off" number should be set. Third, studies have shown significant variability in the volume–outcome relationship within the same registry, with some low volume operators having better than expected outcomes, and a few high volume operators having worse-than-expected outcomes. Furthermore, at present, few or no data exist linking operator volume to case selection, appropriateness of procedures, peri-procedural MI, long-term clinical outcome, or cost effectiveness, each of which measures a component of quality of care....

Additionally:

> ...The development of national, regional, and State registries for outcome assessment is also promoting a shift of the paradigm surrounding quality of angioplasty from a mere collection of procedure volume to objective assessment of clinical outcomes...and as more registry data become available, procedure volume will likely no longer be used as a replacement or a surrogate for quality assessment....

And:

> ...Independent of procedure volume, all operators should participate in a regional or national program for outcome assessment and quality improvement....

In addition to a regular internal review of outcome data, the Program chose from the very start to engage an outside organization to provide peer review as well. As the Program wanted to ensure quality services, outside peer review has been conducted as part of the quality review process.

The Program has also actively participated in two major databases for provision of risk adjusted data comparisons to national and regional programs: the American College of Cardiology-National Cardiac Registry Database (ACC-NCDR) and the Society of Thoracic Surgeons (STS) Database. The Program utilized these comparisons as intended, to evaluate processes and to make improvements if necessary.

The Clinical Competence Statement makes recommendations related to clinical infrastructure including the skill of support staff and the quality of the facilities. During the planning and implementation of the demonstration project, both facilities with the assistance of JDH assured that catheterization labs were upgraded, clinical processes were put into place to ensure excellent care, and a sophisticated data collection system was established. These guidelines have been met and will continue to be met to ensure a quality angioplasty program.

> ...Requirement for Institutional Resources and Support: A high-quality angioplasty program requires appropriately trained, experienced, and skilled physician operators. However, the operator does not work in a vacuum. An operator needs a well-maintained high-quality cardiac catheterization facility to practice effectively. In addition, the operator depends on a multidisciplinary institutional infrastructure for support and response to emergencies. Thus, to provide quality angioplasty services, the institution must ensure that its catheterization facility is properly equipped and managed, and that all of its necessary support services, including data collection, are of high quality and are readily available....

Society of Thoracic Surgeons:

The Society of Thoracic Surgeons (STS) is the nationally recognized professional organization for cardiothoracic surgeons. The STS established a Quality Measurement Task Force to develop a methodology for the comprehensive assessment of adult cardiac surgery quality of care, including both individual measures and an overall composite quality score. The report of the STS Quality Measure Task force entitled, "*Quality Measurement in Adult Cardiac Surgery: Part 1—Conceptual Framework and Measure Selection*" (Appendix 5.i.a.) was published in 2007 and recommends the use of National Quality Forum measures of quality in program evaluation. The STS does not endorse threshold volume for cardiac surgeons or open heart surgical programs (Appendix 5.i.a.). The 2007 report states the following regarding the use of volume as a proxy for quality for CABG procedures:

> ...Structure: Structural measures refer to inherent characteristics of the provider that are believed to be associated with higher quality. These may include, for example, the volume of a particular type of procedure performed annually, advanced information technology such as electronic health records or computerized order entry, participation in an outcomes database registry, sophisticated radiographic imaging capabilities, number of approved residencies, and nurse staffing ratios. For many such measures, the strength of their relationship with desired health care outcomes is not well defined.
>
> Without question, volume is the most extensively studied structural measure of quality in all of medicine and surgery. Whether this reflects "practice makes perfect" or "selective referral" to institutions perceived to be of higher quality is uncertain. The strength of the volume outcome relationship varies widely. For complex procedures such as esophagectomy or pancreatectomy that are performed relatively infrequently even at high volume institutions, the volume-outcome association is strong. For some frequently performed, relatively standardized and mature complex procedures such as CABG, where annual hospital volumes may range from 100 to more than 1000 cases, the volume-outcome relationship is weak.
>
> Structural measures may be useful proxies for outcomes when the latter data are unavailable. Conversely, their relative utility diminishes when reliable outcomes data are accessible. Furthermore, structural measures are often not readily actionable by providers, and this diminishes their usefulness as quality improvement tools....

The leading organization for cardiothoracic surgeons has voiced strong opinions on the matter of volume targets for OHCA to consider in this matter.

American College of Surgeons:

Although this application does not specify other guidelines that will be used in the consideration of this CON, the Applicants submit that The Guidelines for Standards in

Cardiac Surgery (Appendix 5.i.a.) set forth by the American College of Surgeons (ACS) in 1996 are significantly outdated. The 1996 Guidelines state that "current standards of practice form the basis of the report" however, the standards state that the volume guidelines are based on data from 1975. In 1975, cardiac surgery was in its infancy. In 1975 the practice of cardiothoracic surgery did not have the benefit of subsequent years of the additional science and technology that have shaped the practice today.

In 2008, over thirty years later, it is important to consider and review the current status of the medical literature that speaks to cardiac surgery volume and outcomes.

Appendix 5.i.a. provides the most current medical literature to date related to cardiac surgery and the volume-outcome connection. A summary of the literature is also provided below. OHCA defines "utilization" as patterns or rates of use of a single service or type of service; e.g., hospital care, physician visits, prescription drugs (OHCA Glossary of Terms). With regard to evaluation of advanced cardiac services, utilization should be analyzed and evaluated in terms of the overall community serviced and all the procedures provided by the overall Program, not merely one particular interventional procedure. If OHCA intends to continue to define acceptable utilization standards, it is of utmost importance that all factors, literature and current "recommendations" be considered in this process.

Summary of Recent Medical Literature related to Volume and Outcome:

The following is a summary of nine studies and their conclusions. These studies were published subsequent to the approval of the Program in 2004. They demonstrate that there is no clear relationship between volume and outcome, that volume is a poor predictor of quality and that the prior studies that found an association between volume and outcome did not address the effects of surgeon-specific volume. The following more relevant and recent medical literature must be taken into consideration in evaluating any advanced cardiac care Program in the greater Waterbury area.

Ricciardi R., Virnig B. A., Ogilvie J. W., Dahlberg P. S., Selker H. P. & Baxter N.N. (2008). Volume-outcome relationship for coronary artery bypass grafting in an era of decreasing volume. *Archives of Surgery*, 143(4), 338-44.

This study was conducted over a period of 16 years. Study leaders hypothesized that the decrease in hospital procedure volume for CAGB would relate to an increase in the in-hospital mortality rate. It used hospital discharge data from the National Inpatient Sample from January 1, 1988 to December 31, 2003. A 20% random sample of all patients who underwent CABG or angioplasty was used. The study had four different aims including: 1) to determine trends in coronary revascularization techniques performed surgically or by angioplasty; 2) to define trends in valve replacement and repair; 3) to record mortality by year and by CAGB volume to evaluate the effect of declining CABG volume on the volume-outcome relationship, and 4) to quantify the difference in mortality between high and low volume hospitals.

During this period, the rate of CABG increased from 7.2 cases per 1,000 discharges in 1988 to 12.2 cases per 1,000 in 1997 and then declined to 9.7 cases in 2003. During this same period the volume of angioplasty procedures tripled. For CABG, the proportion of high volume hospitals increased to a peak of 32.5%, but then decreased to 15.5% in 2003. During this same time frame, low volume hospitals (12-149 CABG/year) decreased from 49.6% in 1988 to 35.5% in 1997, but then increased to 52.4% in 2003. The numbers of individuals undergoing CABG procedures in low volume hospitals peaked in 2003 at 24.6%. In this 16 year time frame CABG mortality rate declined from 5.4% to 3.3% and in every category of hospital defined by volume, there was a statistically significant decrease in mortality. Hospitals performing the lowest volume of CABG experienced the largest decrease of in-hospital mortality. The study concludes that these results should, "challenge the setting of any arbitrary volume cut point: positive effects on patient outcome are multi-factorial and are inadequately described by procedure volume."

Yuh, D. D. (2008). Volume-outcome relationship for coronary artery bypass grafting in an era of decreasing volume-invited critique. *Archives of Surgery*, 143(4), 344.

In this invited critique the author notes that findings of above study suggest that traditional volume-outcome tenets may be overly simplistic and inaccurate in assessing current CABG practices. The critique notes that there is growing experiential evidence that hospital-based quality control, monitoring and best-practice programs may have a more significant effect on outcomes than volume, particularly in generally routine surgical procedures such as CABG.

Marcin, J. P., Li, Z., Kravitz, R. L., Dai, J. J., Rocke, D. M., & Romano P. S. (2008, February). The CABG surgery volume-outcome relationship: Temporal Trends and Selection Effects in California, 1998-2004. *Health Research & Educational Trust*, 43(1). Retrieved from http://www3.interscience.wiley.com/cgi-bin/fulltext/119390760/PDFSTART

This recently published study examines patient-level clinical data collected from the California CABG Mortality Reporting Program; a voluntary reporting program from 1998 to 2002 involving between 68 and 81 hospitals. In addition, for the years from 2003 to 2004, patient-level clinical data was examined from the California CABG Reporting Program which is a mandatory reporting program in the State of California. This study took place during a transition from the voluntary to the mandatory reporting of CABG outcomes. In this study the patient was the primary unit of study and in-hospital mortality was the primary outcome measured. The study acknowledged previous research in the area of volume and outcomes. It also noted that several recent studies with vigorous statistical methods and the use of risk adjusted data found limited or insignificant relationships between volume and outcome. The data elements collected included patient-level data defined by the STS in addition to data elements defined by other state programs including Massachusetts, New York, New Jersey and Pennsylvania. For this group of multiple hospitals in California it was determined that there was a "consistent but small" volume-outcome relationship for CABG surgery during the years 1998 to

2002, however this relationship disappeared in 2003 and 2004. The study demonstrated, as other more recent studies, that CABG volume may no longer be the quality metric to use to determine Program value. Several reasons were hypothesized for this result including the use of patient specific clinical and risk adjusted data rather than administrative data as well as the advances in surgical practice that have increased overall quality of care to the patient.

Welke K. F., Barnett M. J., Sarrazin M. S. & Rosenthal G. E. (2005). Limitations of hospital volume as a measure of quality of care for coronary artery bypass graft surgery. *Annals of Thoracic Surgery*, 80(6), 2114-9.

This study reviewed over 900,000 Medicare patients for the purpose of quantifying the strength of hospital volume as a predictor of mortality following CABG surgery. Through examination of six years worth of data, the study demonstrated that although on average higher volume hospitals had lower CABG mortality rates than lower volume hospitals, a wide variation in risk-adjusted mortality rates existed among hospitals within similar volume categories and the discrimination of volume as a predictor of mortality was only "slightly better than a coin flip". It concluded that while there are many factors that contribute to the mortality risk of a patient undergoing CABG, hospital volume is a relatively weak predictor.

Khuri S. F. & Henderson W.G. (2005). The case against volume as a measure of quality of surgical care. *World Journal of Surgery*, 29(10), 1222-9.

The purpose of this study was to evaluate the use of volume criteria in setting standards of quality of surgical care. The conclusion of this study was that the use of risk-adjusted outcomes is more appropriate for setting such standards. The author notes that allowing standards based on volume means accepting the premise that low volume hospitals deliver substandard care and high volume hospitals always deliver good care. The author, Dr. Shukri Khuri, has been actively involved in the Veterans Administration National Surgical Quality Improvement Program (NSQIP), the first national, validated, outcome-based and peer controlled program for measuring and enhancing quality surgical care. In contrast to many research studies which have reviewed administrative databases to look at the volume-outcome relationship, NSQIP utilizes a trained nurse to collect prospective clinical data on all major surgical operations in the V.A. This allows for the ability to adequately adjust for patient severity of illness. Work by the NSQIP indicates that volume of surgical workload is unrelated to quality of care and attempts at setting volume as a standard are flawed. NSQIP has found no direct relationship between volumes and outcomes and has demonstrated that the systems of care have more impact on overall outcomes than does volume. Dr. Khuri notes that any threshold volume below which quality is likely to be compromised is illusive at best.

Zacharias A., Schwann T. A., Riordan C. J., Durham S. J., Shah A., Papadimos T. J., Engoren M. & Habib R.H. (2005). Is hospital procedure volume a *reliable* marker of quality for coronary artery bypass surgery? A comparison of risk and propensity adjusted operative and midterm outcomes. *Annals of Thoracic Surgery*, 79(6), 1961-9.

This study reviews the type of system currently in place within the Program [i.e. same surgical team providing services at what are considered Low Volume Hospitals (LVH) and High Volume Hospitals (HVH)]. Zacharias et al. reviewed the results of several recent studies looking at the association between hospital volume and outcome, including a study by Peterson, et al. described below. In these studies, the authors concur that hospital volume-outcome effects are confounded by a significant independent surgeon volume effect. The purpose of this study was to better define whether the procedure volume effects are surgeon or institutional in origin. The study examined 30-day and 3-year mortality for two different institutions served by the same surgical team over a two-year period. The same perfusion team provided bypass services at the two hospitals. Results showed that the two hospitals exhibited multiple demographic and risk factor differences. However, unadjusted operative mortality was similar for the LVH and the HVH (2.38% vs. 2.98%), with nearly identical observed to expected ratios, irrespective of preoperative risk category. Hospital volume did not predict operative mortality. The study concluded that when served by the same high volume surgeons, similar operative and mid-term outcomes may be achieved in LVH and HVH and surgeon experience rather than institutional volume may be the more critical factor. In addition, cardiac surgeons who apply similar patient care standards and pathways and emphasize a team approach to cardiac surgery care can and do achieve similar outcomes at independent low volume and high volume programs.

Peterson E.D., Coombs L.P., DeLong E. R., Haan C. K. & Ferguson T. B. (2004). Procedural volume as a marker of quality for CABG surgery. *JAMA*, 291(2), 195-201.

This study did an observational analysis of 267,089 CABG procedures performed at 439 U.S. hospitals and reported through the STS National Cardiac Data Base. Overall, operative mortality for CABG surgery was 2.66%. After adjusting for patient risk, the rates of operative mortality decreased with increasing CABG volume; however, this association was not observed in patients under the age of 65 or for those with low preoperative risk. Hospital volume generally had poor predictive accuracy as a means of identifying hospitals with significantly better or worse CABG mortality rates. The study indicates, however, that in contemporary practice, hospital procedure volume is only modestly associated with CABG risk adjusted outcomes, and therefore is not an adequate quality metric for CABG surgery. The use of risk adjusted outcomes through national clinical databases should be supported as a measure of quality. The results of this study indicating that the volume-outcome effect is not significant in patients under 65 years of age and in those with low pre-operative risk, imply that prior studies performed exclusively in Medicare patients and without risk stratification would have inflated the volume-outcome effect. The conclusion was that "the closure of up to 100 of the lowest

volume centers (i.e. those performing less than or equal to 150 CABG procedures) would avert fewer than 50 of the 7,110 (less than 1%) of CABG related deaths."

Papadimos T. J., Habib R. H., Zacharias A., Schwann T. A., Riordan C. J., Durham S. J. & Shah A. (2005, May). Early efficacy of CABG care delivery in a low procedure-volume community hospital: operative and midterm results. *BMC Surgery*, 5,10. Retrieved from http://www.pubmedcentral.nih.gov/picrender.fcgi?artid=1131908&blobtype=pdf

The authors note that the studies related to the volume-outcome connection have had varying and sometimes conflicting results. This study reviews the experience with a recently initiated small community hospital cardiac surgery program modeled after a similar high volume program in the same region. The newer program had cardiac surgery services provided by the same surgeons who performed services at an HVH. The authors looked at isolated CABG morbidity and mortality outcomes at the LVH (new program) and compared them to the national data as reported by the STS National Cardiac Data Base over the period of time from February 1, 2001 to December 31, 2003. All CABG procedures at the LVH were performed by the same high volume surgeons who performed CABG procedures at the HVH. The LVH operative mortality did not statistically differ from the STS benchmark. This study paradigm, involving a group of high volume surgeons from a high volume facility establishing a new lower volume program at another facility is similar to the structure of the HCGW Program and demonstrates that high quality CABG care with good outcomes can be achieved at a new lower volume program provided that it is served by high volume cardiac surgeons and backed up by a highly trained dedicated support team.

Kalant N. & Shrier I. (2004). Volume and outcome of coronary artery bypass graft surgery: Are more and less the same? *Canadian journal of cardiology*, 20(1), 81-6.

This research looked at and compared many previously quoted studies relating procedure volume to outcomes. Although in early studies there seemed to be a relationship between volume and procedure outcome, the relationship has diminished over time virtually to zero. The findings of this study, along with the other recent studies, suggest that the evolution of CABG surgery has reduced the importance of the earlier evidence linking volume and outcome. Individual studies may still show a small effect of volume on outcome, but the overall pattern of results does not. Consequently, the combined evidence does not provide support for a policy of regionalization of CABG surgery.

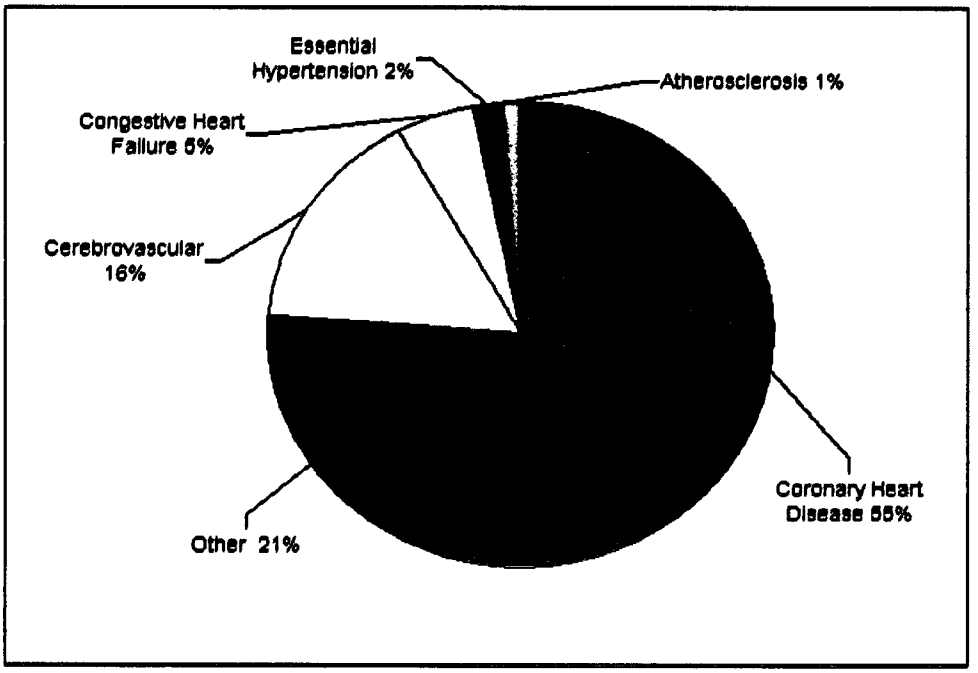
b. Please discuss The Waterbury Hospital ("TWH") and St. Mary's Hospital ("SMH") d/b/a Heart Center of Greater Waterbury's ("HCGW") historical institutional and operator volumes (Elective and Primary Angioplasty and Open Heart Surgery) in relation to the ACC/AHA recommended volume guidelines.

Response:
Related to ACC/AHA **recommended volume** guidelines, the Applicants have met the guidelines in all areas.

As to angioplasty: Individual operator volume for each interventional cardiologist has exceeded the recommended volume number of 75 per year (see Table 7). As to open heart surgery: The ACC/AHA guidelines do not provide a recommended institutional or operator volume. However, the guidelines provide that monitoring should occur for "hospitals or individuals performing less than 100 cases annually." The Program does detailed monitoring of the Program's individual components and as a whole. As indicated in Table 7, the Program's cardiothoracic surgeons have each exceeded 100 cases annually as individual practitioners for the last three years. Three of the four cardiac surgeons at HCGW have practiced for decades. In addition, both campuses have exceeded or been very close to 100 cases each year of the demonstration project. As already noted above, the Program continuously monitors the outcomes and quality of services and, therefore, is in compliance with the recommendations of the ACC/AHA.

As is also noted, the Program participates in the STS National Cardiac database and will continue to do so for the purpose of monitoring National Quality Forum measures and all applicable outcomes.

The HCGW is one Program with two physical locations. All Program cardiologists, cardiac surgeons, cardiac anesthesiologists and perfusion teams practice at both hospital campuses, utilizing the same processes and maintaining the same practices at both campuses. HCGW is one Program with two campuses and its volume as a whole far exceeds any suggested guidelines.



ii. Explain how it was determined there was a need for the proposed interventional cardiac services at SMH and TWH.

Response:
Need for the Program is not hypothetical, estimated or projected. The need for this Program has been demonstrated by the more than 2,400 patients in the three years of operation who have benefitted from the excellent, advanced cardiac services available. Contrast this demonstrated real need from a typical CON that uses statistics, assumptions and estimates to calculate need. This Program has absolute verified data: actual patients served.

Clearly the analysis of the need for this Program must be evaluated in the context of the present Program. That is, in this application OHCA is not faced with the addition of a potential new Program that may change the way services are rendered to a community, but rather with taking away an existing excellent Program. This is unique for OHCA and must be an important factor in any determination of the permanence of this Program. Real lives have been saved by the Program and will be saved in the future.

Coronary artery disease is the number one cause of death in the nation and in Connecticut. As the fourth largest metropolitan area in Connecticut, unfortunately greater Waterbury is not immune from this disease. See Figure 1.

Figure 1. Cardiovascular Disease Deaths, Connecticut Residents - 2002

Source: Connecticut Department of Public Health, Vital Records Mortality Files, 2005

Population:

Detailed population data is provided in the response to question 5.iii.b. However, in summary, as a population ages, the demand for cardiac services significantly increases.

- The growth in total population in the primary service area from 2002 to 2006 was 3%. It is expected to grow by an additional 3% to 281,800 by 2011.

- The population over 45 years of age in 2006 was approximately 40% of the total primary service area population. This is expected to increase through 2011 to 44% of the total population.

- The female portion of the population over 45 years of age in 2006 was 55% of the total. The female portion of the population over 45 years of age is expected to remain at this level through 2011 (source: Claritas Inc.). This is critical in the consideration of present and future cardiac care needs because it has been shown that coronary artery disease in the female population has been under-diagnosed in the past and women have a longer life expectancy than men. CT Women's Health, a 2001 Connecticut Department of Public Health publication (Appendix 5.ii) states that cardiovascular disease is the number one cause of death for Connecticut women. The report notes the sex specific differences in risk factors such as diabetes mellitus and postmenopausal loss of estrogen.

The Connecticut Department of Public Health report on Cardiovascular Disease Issue Brief #2002-1 from February 2002 (Appendix 5.ii) concurs that cardiovascular disease is the leading cause of death for Connecticut's women. It notes that normal estrogen levels in pre-menopausal women provide some protection against heart disease. With the onset of menopause this benefit diminishes and suggests the demand for cardiovascular services may grow at a faster rate for postmenopausal women than for the population as a whole.

Cardiovascular health statistics and risk factors are discussed in the response to question 5.iii.b.

Angioplasty:

Of the over 2,400 patients who have had procedures performed, 1,800 have received angioplasty. Of these, approximately 300 patients have received lifesaving primary angioplasty for ST-Elevation Myocardial Infarction (STEMI).

For those patients suffering from STEMI, research and current medical literature confirm that the time to treatment is critical to survival. The current recommendation to clinicians from the ACC is to treat a STEMI patient within 90 minutes of arrival at an emergency department (Appendix 5.ii). This "door to balloon time" (D2B) measures the time of arrival at the emergency department to the time of initial balloon inflation to open a blocked artery. The faster an artery is opened the less heart muscle is damaged.

Program data (through July 2008) related to treatment of STEMI patients demonstrates that 88% of the patients requiring acute angioplasty are treated in less than 90 minutes. This far exceeds the ACC goal of having 75% of the patients treated in 90 minutes or less. In addition, the Program's average D2B time is 67 minutes. The need to continue with this level of care for the greater Waterbury residents could not be more evident. (See also response to question 6.E.)

Termination of a service that provides excellent time to treatment will increase disability due to time lost and will most certainly cost lives. In the greater Waterbury area an average of 100 citizens per year are treated for STEMI with emergency angioplasty. The need for continuation of life saving services exists because citizens of greater Waterbury are at risk of dying without it. This Program exists because the population of greater Waterbury is at significant risk of preventable death if advanced cardiac services are not available in a timely and quality manner.

The current standard of practice in Connecticut and the recommendation from the ACC/AHA is that hospitals with elective angioplasty have on site open heart surgical back up. Program volumes for angioplasty justify the need for this at both Waterbury campuses. Waterbury, the fourth largest metropolitan area in Connecticut needs a full service cardiac program including elective and primary angioplasty and open heart surgical services.

The Connecticut Hospital Association's CHIME data has shown a statewide decline of 9% in angioplasty volumes from fiscal year 2003 to fiscal year 2008 (annualized through first six months). Despite these trends, utilization of these services at HCGW has exceeded the benchmarks set for the demonstration project. Again, the Applicants submit that statewide trends absolutely do not subvert the need for quality advanced cardiac services provided locally.

Open Heart Surgery:

Three years of recent historical data demonstrate that the need for interventional cardiac services currently exists in greater Waterbury. Over 2,400 patients have utilized the Program for lifesaving and life changing services including over 600 patients who were treated with elective, urgent and emergent open heart surgery.

The Advisory Board Company is an independent "think tank" that provides best practice research and analysis to members of the health care industry. Its Cardiovascular Roundtable, which was the first Advisory Board research group targeted to a particular clinical specialty, conducts research that focuses on best practices and factors that influence practice. With medical advances including new medications and the advent of drug-eluting stents, the Cardiovascular Round Table has documented a decline nation-wide in CABG Surgery (Appendix 5.ii). This has also proven true in Connecticut based on Connecticut Hospital Association data. The Cardiovascular Round Table predicts that some decline will continue through the end of the decade. With recent news reports questioning the safety and long term efficacy of drug-eluting stents, however, this is still open for debate and in fact HCGW physicians purport that the decline will slow and level out. **Conversely**, the demand for valve surgery will increase by 15% through the first decade of the century per the Cardiovascular Roundtable (Appendix 5.ii). Connecticut data mirrors these projections.

CHIME data has shown a statewide decline as predicted in CABG surgery discharges. From fiscal year 2003 to fiscal year 2008 (annualized through first six months) CABG surgery discharges declined 33%. Valve surgery statewide discharges have increased 6% from fiscal year 2003 to fiscal year 2008 (annualized through first six months).

Despite this statewide data, Program data indicates growth of 12% from Program year 1 to Program year 3 for total open heart surgery volume which does not support termination of services. Again, the Applicants submit that statewide trends absolutely do not subvert the need for quality advanced cardiac services provided locally.

iii. Provide the following information for **each** Applicant:

a) Primary and secondary service area towns specific to the proposed interventional cardiac services. Provide the methodology used to delineate the service areas.

Response:
Defining Primary and Secondary Service Area:

Towns comprising the Program's primary service area (PSA) and the secondary service area (SSA) are listed in Table A. HCGW Program data between the years of 2005 and 2008 was analyzed to determine the Program's primary and secondary service areas. The towns analyzed also happen to represent the residency of patients receiving care at both hospitals for the full range of circulatory system disorders. For the purposes of this application, the focus is on advanced cardiac services.

The Connecticut Hospital Association's CHIME data for open heart surgery and angioplasty was utilized in the creation of Table A. In 2007, 92% of angioplasty and open heart surgery patients lived in the 13 towns that make up the PSA. Just over 4% of Program patients lived in the SSA. Future volume projections in the application have been be calculated utilizing data from the Program's PSA. See Table A.

Table A **Saint Mary's Hospital and The Waterbury Hospital**
Combined Cardiovascular Inpatient Patient Origin – Discharges
2005 to 2008 YTD

Town	2005	2006	2007	2008 YTD

Fiscal Year 2008 YTD data represents October 2007 – March 2008

b) Cardiovascular health statistics and risk factors in the service area. Provide evidence

Response:
Several health statistics and risk factors have bearing on the need for a full service cardiac program. They include population data, age distribution, gender data and risk factor prevalence.

Population:

Table B outlines population statistics at the time the original Program planning commenced in 2002 and at the intervals of 2006 and 2011. The population of the PSA continues to grow and supports the need to establish a permanent

cardiovascular program in the Waterbury area. Census data predicts an overall 3% increase in population from 2006 to 2011 (273,163 to 281,800).

Table B **Cardiovascular Primary Service Area Population 2002 to 2011**

Town	2002	2006	2011	2006-2011 % Change
Beacon Falls	5,371	5,582	5,887	5.46%
Bethlehem	3,495	3,648	3,832	5.04%
Cheshire	28,733	29,635	30,566	3.14%
Middlebury	6,910	7,220	7,635	5.75%
Naugatuck	31,110	32,198	33,129	2.89%
Oakville	8,383	8,447	8,681	2.77%
Prospect	8,822	9,280	9,791	5.51%
Southbury	18,974	19,938	21,052	5.59%
Thomaston	7,604	8,121	8,512	4.81%
Waterbury	107,447	108,684	110,314	1.50%
Watertown	13,494	14,076	14,536	3.27%
Wolcott	15,467	16,466	17,458	6.02%
Woodbury	9,328	9,868	10,407	5.46%
PSA Total	265,138	273,163	281,800	3.16%

Source: Claritas, Inc.

Age Distribution:

Age is the most predictive factor for estimating utilization of angioplasty, open heart surgery and cardiac diagnostic services. An aging population will have a higher incidence of cardiovascular and coronary artery disease and a greater need for cardiac diagnostics and therapeutic procedures. The Program's PSA has historically had a higher proportion of older individuals than the State and the nation and data indicates this trend will continue.

Table C **Cardiovascular Primary Service Area Population**
2011 Age Demographics

2011	45 years and over	65 years and over
National	40.0%	13.6%
Connecticut	44.0%	14.9%
HCGW PSA	43.56%	15.36%

Source: Claritas, Inc.

The following shows a significant 11.3% increase in the age 45+ population for the Program's PSA between 2006 and 2011. As stated above, this growth in the aging population signifies a projected increase in demand for care and anticipated increases in the utilization of cardiovascular services.

Table D **Cardiovascular Primary Service Area Age 45+ Population**
2002 to 2011

Town	2002	2006	2011	2006-2011 % Change
Beacon Falls	1,853	2,147	2,526	17.65%
Bethlehem	1,563	1,797	2,042	13.63%
Cheshire	11,068	12,344	13,576	9.98%
Middlebury	3,242	3,572	3,975	11.28%
Naugatuck	10,485	11,806	13,316	12.79%
Oakville	3,177	3,447	3,879	12.53%
Prospect	3,573	4,084	4,661	14.13%
Southbury	9,870	10,770	11,872	10.23%
Thomaston	2,779	3,309	3,871	16.98%

Watertown	5,582	6,310	7,032	11.44%
Wolcott	5,899	6,818	7,908	15.99%
Woodbury	4,057	4,191	5,319	26.91%
PSA Total	101,459	110,281	122,762	11.32%

Source: Claritas, Inc.

Gender:

In addition to the age and general statistics, the female age distribution was analyzed. This information is important since as reported by the Connecticut Department of Public Health, the market demand for cardiovascular services is predicted to grow at a faster rate for postmenopausal women. Additionally, women are living longer than men (Reference Appendix 5.ii). This segment of the population has been inadequately served throughout the United States. Women have been targeted by many hospitals for education regarding the availability of services and are a responsive audience for information.

Census data indicates that the 45+ female segment of the population will increase 10.7% in the Program's PSA between 2006 and 2011. Again, we see indications of an overall increase in cardiovascular demand for the PSA.

Table E Cardiovascular Primary Service Area Age 45+ Female Population 2002 to 2011

Town	2002	2006	2011	2006-2011 % Change

Source: Claritas, Inc.

Risk Factors:

According to the "*The Burden of Cardiovascular Disease in Connecticut: 2006 Surveillance Report", a Connecticut Department of Public Health Report* (Appendix 5.iii.b.), the most prevalent modifiable risk factors for cardiovascular diseases include high blood pressure, high cholesterol, smoking, diabetes, obesity and physical inactivity. Additional key risk factors are increasing age and lower socioeconomic position. All of these risk factors are present and prevalent in the greater Waterbury area and support the need for provision of advanced cardiac services on a local level.

The Center for Disease Control's (CDC) Behavioral Risk Factor Surveillance System (BRFSS) tracks health conditions and risk behaviors in the United States every year. The March 2007 *Community Health Data Scan for Connecticut*, (Appendix 5.iii.b) commissioned by the Connecticut Health Foundation, utilized the BRFSS data in combination with other data sources to identify the risk factors and health status of Connecticut residents. Waterbury, Connecticut is included in the "Manufacturing Center" health reference group (HRG) in this 2007 report. The report identifies the 3 Urban and 10 Manufacturing Centers (including Waterbury) as needing the greatest health-promoting investments. Within these communities, Black/African American and Hispanic residents are in greatest need. These individuals often yield higher rates of risk factors and poor health statistics. This is of particular concern for Waterbury, as these race/ethnic groups comprise approximately half of the total Waterbury population according to www.census.gov (Appendix 5.iii.b).

Cardiovascular risk factor and health statistics for the overall Manufacturing Center HRG are typically higher and more prevalent than Connecticut State averages and are further defined in the sections that follow.

High Blood Pressure:

High blood pressure leads to an added burden on the heart, which results in abnormal heart functioning. Although the rate of high blood pressure is consistent with the State average, as the population continues to age, high blood pressure will also continue to increase and statistics reported through the CDC's BRFSS prevalence data for the State of Connecticut identify that the rate of hypertension among Connecticut residents continues to increase over time.

High Cholesterol:

High cholesterol has a major impact on the increased risk of coronary artery disease. The rate of individuals with high cholesterol in Waterbury is equal to or lower than the State averages, between 24% and 27%. However, even at this percentage rate, the presence of high cholesterol combined with other prevalent risk factors remains of high importance in assessing need for advanced cardiac care.

Smoking:

According to the American Heart Association, a smoker's risk of developing coronary artery disease is two to four times that of a nonsmoker. Additionally, smokers have about twice the risk of nonsmokers for sudden cardiac death for those with coronary heart disease. Cigarette smoking also acts with other risk factors to increase the risk for coronary heart disease. The rate of smoking in Waterbury is higher than average, approximately 23% for all race and ethnicities compared to a State average of 20%.

Source: Community Health Data Scan for Connecticut

Diabetes:

Cardiovascular disease is the primary cause of death for persons with diabetes, accounting for about 65% of the mortality. Diabetic persons are two to four times more likely to develop coronary artery disease than the rest of the population and are

at much greater risk of having a stroke. People with diabetes often have high blood pressure and high cholesterol and are overweight, further increasing their risk for cardiovascular disease (*The Burden of Cardiovascular Disease in Connecticut: 2006 Surveillance Report* Appendix 5.iii.b).

The prevalence of diabetes in Connecticut is comparable to the nation and will increase over time due to the aging population. According to the Connecticut Diabetes Prevention and Control Plan 2007-2012 a recent Connecticut Department of Public Health Publication (Appendix 5.iii.b):

> ...An estimated 163,000 Connecticut adults 18 years and older, have diagnosed diabetes (2003-2005 data). The Centers for Disease Control and Prevention (CDC) estimates that about 30% of all diabetes cases are undiagnosed, partly because symptoms develop gradually and severe symptoms may only occur after several years. An additional 70,000 Connecticut adults are estimated to have undiagnosed diabetes. Thus, a total of 233,000 Connecticut residents are estimated to have either diagnosed or undiagnosed diabetes....

According to the results of the Community Health Data Scan, the rate of diabetic individuals in Waterbury is higher than the State averages for all races and ethnicities, with an average of approximately 6%. It should be noted that the "Black, Not Hispanic" and "Hispanic" groups have almost double the rate of diabetes than the rest of the population.

Statistics reported through the CDC's BRFSS prevalence data for the State of Connecticut identify that the rate of diabetes among Connecticut residents continues to increase over time. Similarly, the Connecticut Diabetes Prevention and Control Plan 2007-2012 concludes that,

> ...the prevalence of diabetes in Connecticut and the United States is likely to increase for a few reasons. First, large segments of both populations are aging. Second, the fastest-growing segment of the U.S. and Connecticut populations include Hispanic Americans and other minority groups, who are considered at higher risk for diabetes nationwide. Finally, Americans are increasingly overweight and sedentary. According to recent estimates, the prevalence of diabetes in the United States is predicted to reach 8.9% of the population by 2025....

Source: Community Health Data Scan for Connecticut

Obesity and Physical Inactivity:

Excess body weight makes the heart work harder and also places individuals at higher risk for high blood pressure, high cholesterol, diabetes, heart disease, and stroke. According to the BRFSS, overweight individuals account for approximately 56% of the Waterbury population, compared to the State average of 53%. The CDC's BRFSS prevalence data for the State of Connecticut shows the rate of obesity increasing over time; however the rate of overweight individuals is declining slightly. This combination of trends could indicate that more individuals categorized as overweight are moving into the obese category. The AHA advises individuals to engage in regular exercise or other physical activity, which helps prevent heart and blood vessel disease. Physical activity can help control blood cholesterol, diabetes and obesity and may help lower blood pressure in some people. The percentage of individuals with no physical activity in Waterbury is higher than the state average at nearly 30%.

Source: Community Health Data Scan for Connecticut

Age:

Although not a modifiable risk factor, increased age is directly linked with a greater risk for cardiovascular disease. As previously noted, approximately 44% of the HCGW primary service area is expected to be over the age of 45 by 2011 which is up from 40% in 2006.

Low Socioeconomic Position:

Persons of lower socioeconomic position reportedly have a higher risk of cardiovascular disease morbidity and mortality, which can be explained by some behavioral risk factors (smoking, hypertension and obesity) that are more prevalent among these persons. It is believed that low-income neighborhood environments may contribute to this increased risk and poorer health outcomes because of such factors as poor air quality, fewer healthy food choices, and lower quality and/or lack of public services. These individuals also tend to be less likely to utilize preventive health services that are important to early detection and treatment. Those with lower income are at higher risk of diabetes those with higher income (*The Burden of Cardiovascular Disease in Connecticut: 2006 Surveillance Report*, Connecticut Department of Public Health. December 2006). (Appendix 5.iii.b.)

With the prevalence of the above risk factors and the overall impact they have on the development of cardiovascular disease as well as other factors including age and socioeconomic statistics of greater Waterbury, it is clear there is a need for advanced cardiac care and community outreach related to prevention activities in this area. Public need for access to advanced cardiac services could not be more convincingly stated.

c) Please complete the following table for each of the Applicants' historical volume related to elective and primary angioplasty and open heart service ("OHS"), including John Dempsey Hospital ("JDH") since the operation of HCGW:

The following statements apply to Questions 5 iii c, d, e, f, g, 5 iv, 5 v and 5 vi:

The fiscal year for SMH and TWH is from October 1 through September 30. All fiscal year 2008 to date items represent data from October 1, 2007 through July 31, 2008. The fiscal year for JDH is from July 1 through June 30 therefore all fiscal year data is for a complete year.

In the tables to follow, volume may be shown as either procedures or discharges. It is understood by OHCA and hospitals that a procedure count can be higher than a count of discharges. Discharges are based on Diagnostic Related Groupings (DRGs) and encompass every procedure that occurs during a single patient hospital stay, while procedure counts involve actual number of cases in the catheterization lab or in the cardiovascular operating room and are reflected by ICD-9-CM codes. (See response to question 5.iii.d.)

In several areas relating to Applicants-only, procedure volume will be shown as it provides a more accurate portrayal of volume and is consistent with internal data collection. The Applicants will indicate the nature of the volume being reported (either procedure or discharge) in the table and/or response.

Response:

Table 1: *Historical* Volume for each Applicant (Institutional) – Procedures

Cardiac Service Legend: A Primary Angioplasty B Elective Angioplasty C Open Heart Service D Cardiac Catheterizations
**JDH is unable to separate out Primary and Elective Angioplasty
Be sure that the volumes provided reconcile with the volumes listed in OHCA Hospital Reporting System, Schedule 450, the CT Office of Health Care Access' Inpatient Discharge Database and the CT Office of Health Care Access Cardiac Registry.

d) Provide all assumptions and calculations utilized to project institutional volumes in Table I.

Response:
Information from the Applicant's internal databases was utilized to complete the table. HCGW maintains one database of all procedures offered on both campuses including angioplasty, open heart surgery and catheterization services. All data is collected based on procedure and procedure date. Examples include:

- A patient has two angioplasties in one hospital stay, both procedures are accounted for in the volume numbers
- If a patient has an angioplasty and during the same admission has CABG surgery, this is counted as one angioplasty and one open heart surgery
- Exception: if a patient has one visit to the catheterization lab and during that visit receives a cardiac catheterization and an angioplasty, this is counted in the procedure count as angioplasty only. The catheterization volumes noted below are for cardiac catheterizations (without accompanying angioplasty).

HCGW utilizes the ACC definitions for all procedures in the catheterization lab and the STS definitions of all open heart surgery procedures. All data is collected at each campus and verified monthly, quarterly and annually for submission to the various

registries including the ACC-NCDR, STS and the CT OHCA cardiac registry. HCGW database is compared against hospital specific statistics periodically which are based on ICD-9 coding and are typically reported based on discharge date. Similarly, JDH maintains an internal database of all procedures including angioplasty, open heart surgery and cardiac catheterization services. JDH has accounted for their volume in the same way as HCGW and utilizes the ACC and STS procedure definitions.

For all Applicants Angioplasty cases are based on the following ICD-9-CM codes: 00.40, 00.45, 00.66, 36.01, 36.02, 36.03, 36.04, 36.05, 36.06, and 36.07.

OHS cases are based on the following ICD-9-CM codes: 35.10 to 35.28, and 36.10 to 36.19.

Cardiac catheterizations are based on the following ICD-9-CM codes: 37.21, 37.22, and 37.23

e) Please provide year-to-date volumes for FY 2008 by Applicant and Service as provided in Table 1. Be sure to include all assumption and calculations.

Response:
Fiscal year-to-date 2008 procedure volumes for all Applicants are provided in Table 1. Assumptions and calculation methodology are outlined in the response to question 5.iii.d.

f) In the following table, provide the last three years of historical volume at HCGW for each Applicant by service and zip code:

Response:
Table 2: Historical Volume for each Applicant by Service and Zip Code is found on the following pages.

iv. Please provide year-to-date volumes for Fiscal year 2008 by Applicant and Service as provided in Tables 2 & 3. Be sure to include all assumption and calculations.

Response:
Fiscal year to date 2008 procedure volumes by service and zip code for all Applicants are provided in Tables 2 and 3.

As in Table 1, for all Applicants the data was collected based on each procedure by procedure date. For each procedure, patient related data such as zip code was collected. In Tables 2 and 3 procedure data was sorted by zip code for primary service area, secondary service area and all other zip codes.

v. In the following table provide the number of patients that were transferred between the Applicants during FYs 2005, 2006, 2007, and year-to-date FY 2008 related to interventional cardiac services. Be sure to cite the reasons as well.

Response:
In the first three years of operation, HCGW occasionally transferred patients to JDH for open heart surgery services as noted below. The surgeons have been able to easily facilitate transfers if necessary or if by patient choice. As expected, transfers have declined with each subsequent year of the demonstration project as community confidence and awareness has grown. There has been no need to transfer any patients from JDH to SMH or TWH.

Transfer of patients between SMH and TWH has not occurred. There is close communication between campuses to redirect patients to SMH or TWH for reasons such as equipment or building maintenance. In cases of this nature, transfer of patients from one hospital campus to the other is not necessary. This is because directing the patient to another campus occurs prior to the patient's arrival at the emergency room through careful planning and communication among the hospitals, physician office, transporter and patient.

Table 4: *Historical* Patient Transfer between the Applicants

	FY 2005 Commencing July 18	FY 2006	FY 2007	FY 2008 YTD	List reasons for transfer
JDH to SMH	0	0	0	0	
JDH to TWH	0	0	0	0	
SMH to JDH	1	5	1	0	1 patient transferred for scheduling reasons due to anesthesia coverage, 1 patient transferred upon request of patient/family, 5 patients transferred based on physician assessment of multiple severe medical issues, multiple risk factors and complexity of surgery
TWH to JDH	0	7	0	1	1 patient transferred for scheduling reasons due to anesthesia coverage, 2 patients transferred upon request of patient/family, 5 patients transferred based on physician assessment of multiple severe medical issues, multiple risk factors and complexity of surgery
SMH to TWH	0	0	0	0	
TWH to SMH	0	0	0	0	

As of July 2006, additional cardiac anesthesiologists joined the Program, decreasing the need to transfer due to anesthesia coverage.

vi. Provide the following for the projected utilization of the proposed service for each Applicant:

Table 5: *Projected* Volume for each Applicant (Institutional) - Procedures

Cardiac Service Legend: A Primary Angioplasty B Elective Angioplasty C Open Heart Service D Cardiac Catheterizations

h) Provide all assumptions and calculations utilized to project institutional volumes in Table 5.

Response:

The assumptions and key calculation data utilized by HCGW will be described first, followed by that of JDH. With each Applicant, actual experience over the last few years served as the foundation for future projections.

HCGW:

As HCGW sought to determine future volumes by service line, a review of historical total market volume, a review of Program specific volume, consultations with Program physicians and a review of demographic and risk factor data took place. The following outlines the major assumptions and key calculation data elements.

Various databases were consulted including Connecticut Hospital Association's CHIME data, Patient Census Report data and HCGW's own internal databases. There is an inherent challenge when utilizing varied data sources for information. What may be categorized as a DRG discharge in one database might be shown as a procedure according to ICD-9-CM codes in another. What is important is that the projected procedure volumes outlined in Table 5 above make inherent sense when one considers all of the variables in total.

Historical Market Volumes & HCGW Market Share

A review of historical PSA volume during the fiscal years 2006, 2007, 2008 indicate an overall PSA market trend of declining discharges for angioplasty and open heart services and a flat-to-modest upward trend for cardiac catheterization procedures (all hospitals). However, during this same period HCGW Program's market capture rate (market share) has increased, a positive indicator for the future.

The Applicants conservatively estimate that HCGW's market share from fiscal year 2008 will remain constant for all services through fiscal year 2011 except open heart surgery. The market share for open heart surgery is estimated to reach the same level of angioplasty market capture in fiscal year 2009 (moving from 75.8% to 80.5%) and then remain constant through fiscal year 2011. Several points serve as the rationale for the estimated increase of open heart surgery market capture. HCGW's open heart surgery market share rates have been steadily increasing since program inception (58.6% fiscal year 2006; 68.3% fiscal year 2007; 75.8% fiscal year 2008). While the interventional cardiologists and cardiologists were well established at the time of Program commencement, the cardiothoracic surgeons were fairly new to the community. The public and local referring physicians are becoming more familiar with the talents of the cardiothoracic surgeons and it is reasonable to assume that the HCGW rate of market capture for open heart surgery will grow to match that of angioplasty services. (See response to question 5.D.b. for further detail regarding market share.)

Actual and Projected HCGW Market Share

Service	Actual FY 2008	FY 2009	FY 2010	FY 2011
PCI	80.5%	80.5%	80.5%	80.5%
OHS	75.8%	80.5%	80.5%	80.5%
I/P Cath	71.7%	71.7%	71.7%	71.7%
O/P Cath	49.3%	49.3%	49.3%	49.3%

Physician Consultations

Consultations with Program interventional cardiologists and cardiothoracic surgeons provided valuable insight that assisted in arriving at the projected volumes. The physicians see the downward volume trend of recent years slowing and leveling out. This is due to the aging population and other risk factors associated with our market. Specific to the HCGW market, our percent of market capture has been growing as the reputation for the Program has broadened and this is expected to hold and even grow in certain segments. It is the physicians' professional opinion that the market projections outlined are appropriately conservative and sound.

Demographics & Risk Factors

Actual experience indicates that the majority of patients that utilize the Program reside in the PSA (see response to question 5.iii a.). As such, the Applicants focused on trends associated with this market when determining future procedure volume.

Primary Service Area Population Projections

2009	2010	2011
278,303	280,044	281,800

Claritas, Inc.

As discussed earlier in the application, the age 65+ population will represent 15.4% of the total PSA population in 2011. Compare this to a national average of 13.6% and a Connecticut average of 14.9%. The age 65+ demographic will have a higher incidence of cardiovascular and coronary artery disease. This and other risk factors are outlined in detail in the response to question 5.iii.b. All were considered as projections were formulated.

Primary /Elective Angioplasty Proportion & Campus Volume Distribution

OHCA requested that the angioplasty projections be categorized as primary and elective. Primary versus elective angioplasty projections were estimated based on HCGW actual data from the initial Program years. The proportions are 15% primary angioplasty / 85% elective angioplasty.

OHCA also requested that HCGW projections be outlined by campus location. Such has been done, but it should be noted that as this is one Program, this is akin to requesting projections regarding specific operating room usage at other open heart surgery programs around the state. Volume distribution between the two campuses for future years was estimated utilizing HCGW actual data from internal records and reflects recent experience. Volume distribution between hospitals is shown below.

Distribution of Volume Between Campuses - Used in Table 5 Projections

Hospital	Primary PCI	Elective PCI	OHS	Cardiac Catheterizations
TWH	61%	57%	62%	57%
SMH	39%	43%	38%	43%
Total	100%	100%	100%	100%

While the HCGW chose to use recent experience when estimating the future volume distribution between campuses, it is interesting to note that differences occur from year to year. Patient preferences and physician referral patterns influence campus choice. One of the advantages of the Program's two campus model is that it optimizes patient access; it allows for the flexibility of patients' and physicians' hospital use patterns.

For example, if one was to look at fiscal year 2007 the volume distribution was somewhat different as outlined below.

EXAMPLE: Fiscal Year 2007 Distribution of Volume Between Campuses

Hospital	Primary PCI	Elective PCI	OHS	Cardiac Catheterizations
TWH	57%	62%	53%	54%
SMH	43%	38%	47%	46%
Total	100%	100%	100%	100%

Had HCGW chosen to use fiscal year 2007 as the basis for future projections, angioplasty volume in fiscal year 2009 would have been projected at 347 procedures on THW campus and 220 procedures on the SMH campus (versus 327 / 240 as shown in Table 5). Similarly, open heart surgery volume in fiscal year 2009 would have been projected at 114 procedures on TWH campus and 101 procedures on the SMH campus (versus 134 / 81 as shown in Table 5). The point of this example is that projections are simply an estimate of something in the future. Actual experience in future years may vary.

JDH:

A historical review of JDH actual volume showed a decline in angioplasty and open heart surgery in the fiscal years 2005 through 2007. By fiscal year 2008, the volume began to grow again. The hospital believes the primary reason for this increase is the considerable investment of capital and human resources in recent years to strengthen the cardiology program, including five new cardiologists coming on board in July 2008. JDH believes this investment as well as the hospital's growing reputation for quality and the growing and aging population in the immediate service area will lead to modest increases in angioplasty and cardiac catheterizations and a small increase in open heart surgery volume in the next three years.

i) In the following table format, please provide the projected first three years of cardiac catheterization volume (by facility) by inpatient and outpatient:

Table 6: *Projected* Cardiac Catheterization Volume for Each Applicant - Procedures

Applicant	FY 2009 (# of Procedures)	I/P	O/P	FY 2010 (# of Procedures)	I/P	O/P	FY 2011 (# of Procedures)	I/P	O/P
TWH	625	294	331	638	300	338	638	300	338
SMH	472	222	250	481	226	255	481	226	255
JDH	498	125	373	509	127	382	520	130	390

Key: Inpatient= I/P, Outpatient= O/P

j) Provide all assumptions and calculations utilized to project institutional volumes in Table 6.

Response:
For the Waterbury based hospitals, the historical split between inpatient and outpatient cardiac catheterizations has been approximately 47% inpatient versus 53% outpatient. At times it would vary year to year however; the above approximation reflects an average historical view. The projection for fiscal years 2009 to 2011 is based on this historical split.

With regard to JDH, over the last two years approximately 25% of diagnostic cardiac catheterization cases have occurred on an inpatient basis and 75% on an outpatient basis. JDH is projecting this ratio will remain stable over the next three years.

A review of Patient Census Report data shows that inpatient versus outpatient cardiac catheterization splits among hospitals vary. As such, it is not unusual for HCGW and JDH to have different inpatient to outpatient ratios. (Reference Appendix 5.D.c).

k) Provide the historical operator volume by unique physician identifier currently providing services at each Applicant's facility as follows:

Response:
Table 7: Historical Operator Volume for each Applicant is found on the following pages.

Table 7: Historical Operator Volume for each Applicant - Procedures

Cardiac Service Legend: A Primary Angioplasy B Elective Angioplasty C Open Heart Services D Cardiac Catheterizations

Fiscal Year to Date 2008: HCGW October 1 - July 31 ; JDH July 1 - June 30; Hartford Hospital October 1- July 31

l) Please provide year-to-date volumes for FY 2008 by Operator and by Facility and Service as provided in Table 7. Be sure to include all assumption and calculations.

Response:
Fiscal year to date 2008 procedure volumes by operator, facility and service for all Applicants are provided in Table 7. Assumptions and calculation methodology are outlined in the response to question 5.iii.d.

m) Provide the projected operator volume by unique physician identifier currently providing services at each Applicants' facility as follows:

Response:
Table 8: Projected Operator Volume for each Applicant is shown on the following pages.

Table 8: Projected Operator Volume for each Applicant - Procedures

n) Provide all assumptions and calculations utilized to project operator volumes in Table 8.

Response:
For all Applicants fiscal year 2008 physician data was analyzed to determine the proportion of services provided at all facilities. Assuming no change in physician rosters or in practice patterns the proportions were kept constant for fiscal years 2009 through 2011.

o) In the following table format, please provide projected cardiac catheterization volume by inpatient and outpatient, by operator and facility.

Response:
Table 9: Projected Cardiac Catheterization Volume by Operator is found on the following pages.

Table 9: Projected Catheterizations Inpatient (IP) and Outpatient (OP) by Physician

p) Provide all assumptions and calculations utilized to project operator volume by facility in Table 9.

Response:
For all Applicants fiscal year 2008 physician data was analyzed to determine the proportion of services provided at all facilities. Assuming no change in physician rosters or in practice patterns the proportions were kept constant for fiscal years 2009 through 2011.

B. Please address the following questions regarding the existing providers:

a. Identify the existing providers of interventional cardiac services that will be affected by this proposal.

Response:
HCGW is the sole provider of advanced cardiac services in the greater Waterbury service area. The addition of these services in 2005 has allowed the entire region and specifically over 2,400 community members and their families the ability to be cared for locally in their community hospital, by local physicians with excellent quality outcomes, in an environment with which they are comfortable and by providers in whom they have tremendous confidence. A review of program data demonstrates that approximately 90% of the patients served by the interventional cardiac Program are from the primary service area and, as such, no other providers will be significantly affected by the replacement of the current services under the new CON. This Program must be evaluated in the context of being an existing advanced cardiac service program and as such should have little impact on other existing programs.

b. Please explain how these aforementioned providers of interventional cardiac services will be affected by your proposal (i.e. patient volume, quality of care, etc.).

Response:
Based on historical data from the greater Waterbury area prior to the commencement of the demonstration project, cardiac services for area citizens was for the most part provided at hospitals to the south of Waterbury. Therefore, no discussion or analysis related to existing programs in Hartford or Farmington is provided in this response. Existing providers of interventional cardiac services located in Bridgeport, Danbury and New Haven should see no additional effect on the services that they currently provide. Illustrated below is the number of discharges for fiscal year to date 2008 by aforementioned hospitals for each HCGW primary service area town. Over the last three years the majority of patients have chosen to stay locally for their cardiac care.

Source: CHIME decision support tool

Currently HCGW is capturing 80% of the market share for angioplasty, 84% of the market share for CABG, and 65% of the market share for valve surgery in the primary service area. Future projections indicate that the other existing providers should see no significant impact on volumes as a result of HCGW.

c. Discuss in detail the impact HCGW has had on these providers (i.e. volume, quality of care, etc.) over the past three years HCGW has been in operation.

Response:

The tables portrayed in the response to question 5.B.c illustrate discharge volume as taken from the CHIME decision support tool.

Danbury Hospital:

HCGW began providing advanced cardiac services in July 2005. Danbury Hospital (DH) began providing interventional cardiac services in January 2005. With no historical data for DH and a service area that includes Western Connecticut and nearby New York, it is not apparent that HCGW has had any impact on the volumes of DH. The Town of Southbury, in HCGW's primary service area, has a volume of interventional procedures including angioplasty and open heart surgery that is typically split with DH per CHIME data.

The DH website notes that it has been named to the Solucient Top 100 Hospitals® for better patient safety, shorter length of stay and lower mortality (death rate) than its peer hospitals. The Program assumes no impact on the quality of care at DH.

Bridgeport Hospital:

According to CHIME data open heart surgery discharges for Bridgeport Hospital (BH) from fiscal year 2003 to fiscal year 2008 are shown below:

BH	FY 2003	FY 2004	FY 2005	FY 2006	FY 2007	FY 2008
CABG	214	171	153	92	96	60
Valve	76	71	90	68	77	48
Total OHS	290	242	243	160	173	128

Based on DRG 547,548,549,550,104,105,106
FY 08 is YTD through March 2008 (annualized)

In fiscal year 2003, 15% or 44 cases of BH total open heart surgery volume came from the primary service area of HCGW. In fiscal year 2008, 0% of cases of BH total open heart surgery volume came from the primary service area of HCGW. The overall decline in volumes at BH, however, cannot be solely attributed to HCGW. Decreasing volume, consistent with the statewide decline in open heart surgery volumes, had been noted at BH prior to the opening of HCGW. In addition, St. Vincent's Medical Center (SVMC) in Bridgeport, with presumably the same service area, has surpassed BH in volume capture from fiscal year 2003 to fiscal year 2008.

According to CHIME data in fiscal year 2003, 32% or 400 cases of BH total angioplasty discharges came from the primary service area of HCGW. In fiscal year 2008, 0.3% of the cases of BH total angioplasty volume came from the primary service area of HCGW. The overall decline in volume at BH cannot be solely attributed to HCGW. In fiscal year 2006, when volumes started to significantly decline, DH also began providing angioplasty. In addition, the discharges at SVMC have significantly surpassed the discharges of BH from fiscal year 2006 to fiscal year 2008 as noted below:

Hospital	FY 2003	FY 2004	FY 2005	FY 2006	FY 2007	FY 2008
BH-PCI	1263	1329	1103	761	598	600
SVMC-PCI	592	976	1070	1131	1055	1052

Based on DRG 518,555,556,557,558
FY 08 is YTD through March 2008 (annualized)

As to quality, unlike HCGW, BH is under no obligation to report quality data to the CT OHCA Cardiac Registry. Therefore, quality data is not accessible to the public. However, according to the BH website, BH is the only Connecticut hospital named as one of the nation's 100 Top Hospitals® for cardiovascular care by Thomson Healthcare (formerly Solucient) in 2005, 2006 and 2007. Delivery of quality cardiac

services does not appear to have been effected at BH despite volumes that have decreased over time.

St. Vincent's Medical Center:

According to CHIME data, open heart surgery discharges for SVMC from fiscal year 2003 to fiscal year 2008 are shown below:

SVMC	FY 2003	FY 2004	FY 2005	FY 2006	FY 2007	FY 2008
CABG	215	212	180	150	127	132
Valve	52	65	92	88	93	114
Total OHS	277	287	272	238	220	246

Based on DRG 547,548,549,550,104,105,106
FY 08 is YTD through March 2008 (annualized)

In fiscal year 2003, only 1.8% or 5 cases of SVMC total open heart surgery volume came from the primary service area of HCGW. In fiscal year 2008 that had decreased to 1.6% or 2 cases. With the overall decline in open heart surgery volumes statewide and at SVMC, it cannot be presumed that this was due to the HCGW Program.

During this same timeframe, angioplasty volumes at SVMC significantly increased as shown above in the comparison to BH. A 78% increase in angioplasty volumes at SVMC is noted from fiscal year 2003 to fiscal year 2008. In addition, total interventional cardiac volume (angioplasty and open heart surgery combined) increased 49% during the same time period. SVMC has demonstrated growth in its comprehensive cardiovascular services despite the introduction of HCGW as well as the DH program.

As to quality, SVMC is also not obligated to report quality data to the CT OHCA Cardiac Registry. However, the SVMC websites notes that SVMC is "A recipient of HealthGrades 2007 Cardiac Care Excellence Award. St. Vincent's was named to the top 10% in the nation for cardiac care, including surgery, interventions and the treatment of heart attack and heart failure. It is the second consecutive year that St. Vincent's has earned national distinction for "Five Star" interventions in the study." Quality at SVMC appears not to have been affected by other programs.

Yale-New Haven Hospital:

According to CHIME data open heart surgery discharges for Yale-New Haven Hospital (YNNH) from fiscal year 2003 to fiscal year 2008 are shown below:

YNHH	FY 2003	FY 2004	FY 2005	FY 2006	FY 2007	FY 2008
CABG	522	461	455	333	318	312
Valve	352	369	353	341	322	362
Total OHS	874	830	808	674	640	674

Based on DRG 547,548,549,550,104,105,106
FY 08 is YTD through March 2008 (annualized)

In fiscal year 2003, 14% or 122 cases of YNNH total open heart surgery volume came from the primary service area of HCGW. In fiscal year 2008 that had decreased to 3.8% or 26 cases. The overall decline in open heart surgery procedures at YNNH cannot solely be attributed to HCGW. Factors including the decline in statewide open heart surgery volumes, the opening of two new open heart surgery programs in fiscal year 2005, as well as a second open heart surgery program in New Haven could all have impacted YNNH.

According to CHIME data angioplasty discharges for YNNH from fiscal year 2003 to fiscal year 2008 are shown below:

YNHH	FY 2003	FY 2004	FY 2005	FY 2006	FY 2007	FY 2008
PCI	1866	1502	1378	1288	1204	1250

Based on DRG 518,555,556,557,558
FY 08 is YTD through March 2008 (annualized)

In fiscal year 2003, 16% of the angioplasty volume at YNNH originated from the HCGW primary service area. In fiscal year 2008, 1.8% of the angioplasty volume at YNNH originated from the HCGW primary service area. As above, the same factors apply to angioplasty as to open heart surgery. The statewide decline in angioplasty, the opening of three new angioplasty programs in fiscal year 2005 and fiscal year 2006, as well as a second angioplasty program in New Haven could all have had an impact.

Similar to BH and SVMC, YNNH is not obligated to report quality data to the CT OHCA Cardiac Registry. However, the YNNH website posted on July 11, 2008, the following announcement demonstrating that the quality of care has not been compromised at YNNH:

> ...For the second consecutive year, *U.S. News & World Report* has named Yale-New Haven Hospital (YNHH) to its national honor roll as one of the top hospitals in the United States. YNHH is ranked 19th in the U.S. according to the publication's annual "America's Best Hospitals" ranking in the July 14 issue. Yale-New Haven Hospital was one of only three New England hospitals to be selected, joining Massachusetts General Hospital and Brigham and Women's Hospital, both of Boston, on the 2008 honor roll....

Hospital of Saint Raphael:

According to CHIME data, open heart surgery discharges for Hospital of Saint Raphael's (HSR) from fiscal year 2003 to fiscal year 2008 are shown below:

HSR	FY 2003	FY 2004	FY 2005	FY 2006	FY 2007	FY 2008
CABG	484	406	292	226	215	180
Valve	168	163	153	91	97	102
Total OHS	652	569	445	317	312	282

Based on DRG 547,548,549,550,104,105,106
FY 08 is YTD through March 2008 (annualized)

In fiscal year 2003, 27% or 177 cases of HSR total open heart surgery volume came from the primary service area of HCGW. In fiscal year 2008 that had decreased to 1.4 % or 4 cases. The decline in open heart surgery procedures from fiscal year 2003 to fiscal year 2008 at HSR cannot solely be attributed to HCGW. Factors including the decline in statewide open heart surgery volumes, the opening of two new open heart surgery programs in fiscal year 2005, as well as a second open heart surgery program in New Haven could all have had an impact.

According to CHIME data, angioplasty discharges for Hospital of HSR from fiscal year 2003 to fiscal year 2008 are shown below:

HSR	FY 2003	FY 2004	FY 2005	FY 2006	FY 2007	FY 2008
PCI	960	996	727	713	654	624

Based on DRG 518,555,552,557,558
FY 08 is YTD through March 2008 (annualized)

In fiscal year 2003, 12% of the angioplasty volume at HSR originated from the HCGW primary service area. In fiscal year 2008, 3.8% of the angioplasty volume at HSR originated from the HCGW primary service area. As above, the same factors apply to angioplasty as to open heart surgery. The statewide decline in angioplasty, the opening of three new angioplasty programs in fiscal year 2005 and fiscal year 2006, as well as a second angioplasty program in New Haven could all have impacted HSR.

HSR is also not required to submit quality data to OHCA, however, www.hospitalcompare.hhs.gov reports hospital level data for Medicare recipients in key quality areas. According to this website HSR demonstrates compliance in 100% of the Heart Attack Process Care Measures and it reports that 84% of STEMI patients are re-perfused in less than 90 minutes. This seems to demonstrate that HSR has an acceptable level of quality for these services.

Conclusion:

The volumes at the existing programs have been impacted by multiple factors including advances in cardiac medicine for prevention and early treatment of heart disease and improvements in cardiovascular surgical and interventional techniques which are difficult to quantify. Although it may be presumed that a percentage of volume from the greater Waterbury area has been shifted to the HCGW (a Program that can provide timely access to excellent care and that is in close proximity to area residents) it has not seemed to impact the quality of and access to care that residents in the Danbury, Bridgeport and New Haven areas are receiving.

C. Will your proposal remedy any of the following barriers to access? *Please provide an explanation.*

☒	Cultural	☒	Transportation
☒	Geographic	☒	Economic
☐	None of the above	☒	Other (Identify) Access to timely life saving care.

If you checked other than None of the above, please provide an explanation.

Response:
The people of the greater Waterbury community are the sole reason the Program was developed and implemented. This community needs and deserves access to advanced cardiac care available in a timely, cost-efficient manner. The following barriers to access were addressed over the last three years with continued improvement expected with approval of a permanent advanced cardiac Program.

Cultural:

The greater Waterbury area, and Waterbury in particular, has several cultural factors which put residents at distinct risk. Continued local access to a quality full-service cardiac Program will allow residents to benefit from a decreased risk of mortality.

According to the most recent US 2000 Census data, (Appendix 5.iii.b) approximately 50% of the Waterbury population is Black, Hispanic, or other minority. The Connecticut Department of Public Health report titled "The Burden of Cardiovascular Disease in Connecticut 2006 Surveillance Report" (Appendix 5.iii.b) reports that, "Coronary Heart Disease (CHD) death rates differ by race, ethnicity and gender with Black (non-Hispanic) males and females having significantly higher CHD death rates compared with White (non-Hispanic) males and females, respectively ($p<.01$)".

Similarly, the report indicates that Black (non-Hispanic) residents have higher hospitalization rates for CHD and age adjusted premature mortality from CHD compared with White (non-Hispanic) and Hispanic residents.

The key risk factor for all cardiovascular diseases is increasing age. Per the report, 86% of all deaths from CHD occurs in those over the age of 65. Population data for the greater Waterbury area demonstrates that by 2011 15.4% of the population in the HCGW primary service area will be over 65 years of age.

Geographic:

An advanced cardiac care Program in Waterbury eliminates any barriers related to travel for the care needed. Over the last three years patients have overwhelmingly chosen to

stay in the greater Waterbury area for the care they need. This is demonstrated by the fact that approximately 90% of patients live in the Program's primary service area. Any change to the current delivery of services would create a geographic barrier to care that is unnecessary and burdensome and catastrophic to the citizens of greater Waterbury.

Transportation:

The demonstration project eliminated transportation issues related to cardiac care and in particular emergency cardiac care. Patients in need of immediate cardiac care have not been transferred to other distant emergency rooms for timely reperfusion, but instead have been treated at either campus to which they are brought by ambulance. As a result, STEMI patients are arriving at the catheterization labs and are having their arteries opened in under 90 minutes 88% of the time. This is superior when compared to just over three years ago when this occurred 0% of the time due to the transportation time to other facilities.

In addition, families are no longer required to travel to cities 25-30 miles away to be with their loved ones while they receive care. With the current cost of gasoline at close to $4.00 per gallon, thousands of dollars per year will be saved by local families if there is no need to drive to other cities.

The demonstration also allowed local ambulance companies to attend to patients in this area without the burden and cost of transporting patients to distant cities, therefore, bringing them outside of the typical service area (Appendix 5.C).

Economic:

According to US 2000 Census Data, the median household income in Waterbury was reported at approximately $34,000 per year (as compared to $53,000 for the State as a whole). Only 14% of the population has a Bachelors Degree or higher. The Connecticut Economic Resource Center (www.cerc.com) reports that 16% of the Waterbury population is living under the poverty line (Appendix 5.C).

Additionally, the socio-economic profile in Waterbury is well documented in the May 2007 *Office of Health Care Access Report of Investigative Proceedings* - (Appendix 5.C), showing that Waterbury and its neighboring towns of Naugatuck and Watertown have:

- *A higher percentage of residents over 75 years old (which as a group has the highest potential to suffer from chronic diseases including cardiac disease that needs management).*
- *Minorities that have high hospitalization and uninsured rates.*
- *A labor force that has a comparably higher tendency to work in service, production, transportation and material moving industries that are seasonal, temporary or part-time in nature.*

The table below illustrates other socio-economic factors that impact Waterbury. Lack of education, higher unemployment and lower household incomes are key contributors to the status of the local economy.

Selected Socio-Economic Statistics						
	% High School Graduation	% with Bachelor's Degree or Higher	% of Civilian labor force Unemployed	% in Mg't Professional related Jobs	% in Service/ Sales/ Transp. Jobs	Average Household Income
Waterbury	71.7	13.9	8.6	25.1	55.9	51,888
State of CT	84	31.4	5.6	39.1	52.8	82,601

Source: US Census Bureau 2000

These socio-economic statistics and Program data indicate that some of Connecticut's most vulnerable patients make up the population of greater Waterbury and would be greatly impacted if there was a need to return to receiving care at facilities in New Haven, Bridgeport or elsewhere. Residents rely on our city hospitals to provide for their needs as many do not have adequate transportation and support systems to seek services in distance cities. Similarly, travel, food and lodging costs for families desiring to visit or stay with patients who may receive care in distant cities, would be an unnecessary burden and a barrier to supportive care.

The Connecticut Department of Public Health report titled "The Burden of Cardiovascular Disease in Connecticut 2006 Surveillance Report" (Appendix 5.iii.b) also reports that lower socioeconomic position is an important risk factor for cardiovascular disease (CVD). This is measured by personal income, household income or educational level attained. As behavioral risk factors such as smoking, hypertension and obesity are more prevalent with individuals in with lower socioeconomic standing, this correlates to higher incidences of CVD. Similarly, those with lower incomes tend to use preventative health services less frequently further increasing their health risks.

Local access to services to prevent, diagnose and treat cardiac health issues is critical to the well being of the greater Waterbury population.

Timely Access to Treatment:

A significant barrier that will be remedied by the establishment of a permanent cardiac Program is the barrier to timely treatment for cardiac care. Prior to the approval of the demonstration project, citizens of greater Waterbury were forced to travel to hospitals miles away for care that they so desperately needed. Prior to 2005, advanced cardiac services were only available in Farmington, Hartford, New Haven and Bridgeport.

The current accepted standard of care is that STEMI patients are treated in 90 minutes or less. Recent Program data shows that through July 2008 greater Waterbury residents were being treated in an average of 67 minutes. Access to this level of timely care would not be available without the Program. Transporting patients to distant cities should not be a consideration when lives are at stake and qualified physicians and hospitals are available locally.

D. Have the Applicants conducted a Needs Assessment and a Market Share Analysis for the proposed cardiac services?

a. If the response is No, please explain in detail why not and what did the Applicants utilize to assess the need for this proposal?

Response:
This question assumes a hypothetical consideration of what a future Program could mean to a not previously serviced region. No needs assessment was undertaken because the Program exists and rather than relying on projections and estimates, real verifiable evidence is available. The patients served, the market share and the quality of the Program overwhelmingly demonstrate the need for a permanent Program with the full continuum of advanced cardiac care for the region. In addition, need was clearly identified through the analysis of a variety of secondary data sources that outline national, state and local community need, health risks and conditions. In addition to these data sources, data collected in the three year history of service provision to the greater Waterbury area is sufficient evidence to demonstrate the ongoing need for advanced cardiac services.

These secondary data sources have been summarized in response to questions 5.ii and 5.iii.b and are available for review in Appendices 5.ii and 5.iii.b.

b. If yes, explain in detail what Needs Assessment and Market Share Analysis were conducted, the process and the results.

Response:
A market share analysis was conducted utilizing the Connecticut Hospital Association's CHIME data and Patient Census Report (Appendix 5.D.c).

CHIME inpatient discharge data for the following DRGs was included in the analysis.

Angioplasty:	518, 555, 556, 557, 558
Valve Surgery:	104, 105
CABG:	106, 547, 548, 549, 550

Because CHIME data does not provide outpatient statistics, the Patient Census Report for fiscal year end 2006 and 2007 and fiscal year to date June 2008 were used to identify inpatient and outpatient cardiac catheterization procedures.

The primary service area volumes* for each service were summarized for each hospital, by fiscal year. The individual hospital totals were compared to the total volumes* originating from the primary service area as a whole to determine hospital market share. SMH and TWH volumes* were combined to create the HCGW market share. All other hospitals were grouped into an "other" category.

SMH + TWH PSA Volume* ÷ Total PSA Volume*= HCGW PSA Market Share
*CHIME discharges for angioplasty and open heart surgery & PCR procedures for cardiac catheterizations

It is noteworthy that the Patient Census Report does not provide zip code level data to identify the procedures that originate from the primary service area. Therefore, the HSA 5 town grouping served as a suitable proxy. For the purpose of the market share projections for catheterization procedures, the HSA 5 totals are assumed to be the total market. In all likelihood, HSA 5 represents a greater number of catheterization procedures than actually originate from the HCGW PSA, and as such the estimated market share resulting from this analysis is a more conservative estimate than actual market share.

Primary Service Area Market Volume

	FY 2006		FY 2007		FY 2008 YTD (3)	
	HCGW	Other Hospitals	HCGW	Other Hospitals	HCGW	Other Hospitals
PCI (1)	**570**	**155**	**534**	**156**	**251**	**61**
OHS (1)	**167**	**118**	**185**	**86**	**91**	**29**
Valve	51	56	61	46	33	18
CABG	116	62	124	40	58	11
Catheterizations (2)	**1426**	**967**	**1554**	**849**	**1154**	**691**
Inpatient	847	412	1024	378	781	308
Outpatient	579	555	530	471	373	383

(1) Discharges per CHIME
(2) Procedures per Patient Census Report
(3) Discharges: October to March 2008; Procedures: October to June 2008

Primary Service Area Market Share
% of Market Capture

	FY 2006		FY 2007		FY 2008 YTD (3)	
	HCGW	Other Hospitals	HCGW	Other Hospitals	HCGW	Other Hospitals
PCI (1)	**78.6%**	**21.4%**	**77.4%**	**22.6%**	**80.5%**	**19.6%**
OHS (1)	**58.6%**	**41.4%**	**68.3%**	**31.7%**	**75.8%**	**24.2%**
Valve	47.7%	52.3%	57.0%	43.0%	64.7%	35.3%
CABG	65.2%	34.8%	75.6%	24.4%	84.1%	16.9%
Catheterizations (2)	**59.6%**	**40.4%**	**64.7%**	**35.3%**	**62.6%**	**37.5%**
Inpatient	67.3%	32.7%	73.0%	27.0%	71.7%	28.3%
Outpatient	51.1%	48.9%	53.0%	47.1%	49.3%	50.7%

(1) Discharges per CHIME
(2) Procedures per Patient Census Report
(3) Discharges: October to March 2008; Procedures: October to June 2008

The results of the analysis show constant growth in market share for HCGW and a significant slowing of outmigration, which indicates that patients originating from the proposed service area are selecting to receive their cardiac care locally.

c. Provide a copy of the Needs Assessment and the Market Share Analysis conducted by the Applicants.

Response:
The secondary data sources used to assess need are included in Appendices 5.ii and 5.iii.b. The hospital specific market share excerpts from CHIME Data are noted in the response to 5.D.b. and the cardiac catheterization data excerpted from the Patent Census Reports are included in Appendix 5.D.c.

E. Provide copies of any of the following plans, studies or reports *related to your proposal:*

☐ Epidemiological studies ☐ Public information reports

☒ Other (Identify) see below

Response:
All recent medical literature and guidelines and governmental reports are included in Appendices appropriately labeled by question 5.1.a.

6. Quality Measures

A. Check off all the Standard of Practice Guidelines that will be utilized by the Applicants for the proposed services. Please submit the most recent copy of each report related to the proposal:

☒ American College of Cardiology	☐ National Committee for Quality Assurance	☐ Public Health Code & Federal Corollary
☐ National Association of Child Bearing Centers	☐ American College of Obstetricians & Gynecologists	☐ American College of Surgeons
☐ Report of the Inter-Council for Radiation Oncology	☐ American College of Radiology	☒ Other: Specify: Society of Thoracic Surgeons

Response:
See Appendix 5.1.a. for above referenced guidelines.

B. Explain how the Applicants plan to meet the American College of Cardiology/American Heart Association practice guidelines related to this proposal. If the Applicants do not expect the proposed interventional cardiac Program to meet these guidelines and protocols, please explain how quality of the interventional cardiac Programs will be maintained in relation to the ACC/AHA guidelines.

Response:
As to Angioplasty:

The Program will continue to meet ACCF/AHA/SCAI 2007 Update of The Clinical Competence Statement on Cardiac Interventional Procedures as well as the ACC/AHA/SCAI 2005 Guideline Update for PCI (Appendix 5.i.a). Individual operator (minimum volumes of 75 per physician) will continue to be met. The Program will continue to participate in the D2B Alliance for Quality (see response to question 6.E) and will continue to submit data to the ACC-NCDR for benchmarking and quality improvement purposes.

The Applicants will monitor risk adjusted outcomes and continue to meet all CT OHCA cardiac registry data reporting requirements as well as any future State mandated data reporting requirements.

As to Open Heart Surgery:

As per the response to question 5.i.a., the Program expects to continue to meet the guidelines set forth for angioplasty and open heart surgery. The ACC/AHA revised Guideline Update for Coronary Artery Bypass Graph Surgery (CABG) published in 2004

is the most recent ACC/AHA guidelines for open heart surgery. *Section 7 Institutional and Operator Competence, 7.1 Volume Consideration* states: (Appendix 5.i.a).

> ...In summary, studies suggest that survival after CABG is negatively affected when carried out in institutions that perform less than a threshold number of cases annually. Similar conclusions have been drawn regarding individual surgeon volumes. In states where reporting of outcomes is an accepted practice (e.g., New York State), the relationship between low volumes at either an institutional or individual level seems to have diminished over time. This observation strengthens the argument for outcome tracking and supports a posture of close monitoring of institutions or individuals that perform less than 100 cases annually. It must be remembered that these same studies also found a wide variation in risk-adjusted mortality rates in low volume situations; i.e., some institutions and practitioners maintained excellent outcomes despite relatively low volumes....

The above referenced Guideline Update for CABG Surgery continues to support the argument for monitoring clinical outcomes in those programs that perform less than 100 cases annually. However, the guidelines do not support the position that quality programs with an institutional volume of less than 100 surgical cases not be allowed to operate. As a Program, HCGW performed over 100 surgical cases and as demonstrated in the application, is projected to do so. These guidelines refer to surgeon volume as well and as stated in the response to question 5.i.b., this may be a more important issue for OHCA to consider as it evaluates the permanency of the Program.

The application for the original demonstration project referred to the American College of Surgeons Guidelines for Cardiothoracic Surgery and volume targets were set in part based on these guidelines. The Applicants do not support the use of these Guidelines as previously stated in the response to question 5.1.a. because they are significantly outdated and there are more relevant and reliable recent studies that should be considered instead

More relevant is the report of the STS Quality Measure Task Force entitled *Quality Measurement in Adult Cardiac Surgery: Part 1—Conceptual Framework and Measure Selection* (Appendix 5.i.a.) that was published in 2007 and recommends the use of National Quality Forum measures of quality in program evaluation. The STS does not endorse threshold volume for cardiac surgeons or open heart surgical programs (Appendix 5.i.a). The 2007 states the following regarding the use of volume as a proxy for quality for CABG procedures:

> ...Structure: Structural measures refer to inherent characteristics of the provider that are believed to be associated with higher quality. These may include, for example, the volume of a particular type of procedure performed annually, advanced information technology such as electronic health records or computerized order entry, participation in an outcomes database registry, sophisticated radiographic imaging capabilities, number of approved residencies, and nurse staffing ratios. For many such measures, the strength of their relationship with desired health care outcomes is not well defined....

...Without question, volume is the most extensively studied structural measure of quality in all of medicine and surgery. Whether this reflects "practice makes perfect" or "selective referral" to institutions perceived to be of higher quality is uncertain. The strength of the volume outcome relationship varies widely. For complex procedures such as esophagectomy or pancreatectomy that are performed relatively infrequently even at high volume institutions, the volume-outcome association is strong. For some frequently performed, relatively standardized and mature complex procedures such as CABG, where annual hospital volumes may range from 100 to more than 1000 cases, the volume-outcome relationship is weak....

The Program is committed to monitoring its outcomes and utilizing the STS national data registry to identify potential areas of improvement. Program physicians ardently support the use of the STS database for monitoring outcomes.

C. Submit a list of all key professional and administrative personnel, including the Chief Executive Officer (CEO) and Chief Financial Officer (CFO), Medical Director of Interventional Cardiac Program, Cardiac Surgeons, Interventional Cardiologists, etc. related to the proposal and a copy of their Curriculum Vitae.

Note: For physicians, please provide a list of hospitals where the physicians have admitting privileges.

Response:
Curriculum Vitae of those below are provided in Appendix 6.C.

Name	Title	Hospital	Admitting Privileges
John Tobin	President and CEO	TWH	Not applicable
William Casey	Interim President and CEO	SMH	Not applicable
James Thornton	Hospital Administrator	JDH	Not applicable
Colleen Scott	CFO	TWH	Not applicable

David D'Onofrio	Perfusionist	TWH SMH JDH	Not applicable
Ronald Salonia	Perfusionist	TWH SMH JDH	Not applicable
Paul Juregei	Perfusionist	TWH SMH JDH	Not applicable

D. Provide a copy of the most recent inspection reports and/or certificate for each facility:

☒	DPH	☒	JCAHO
☒	Fire Marshall Report	☐	AAAHC
☐	AAAASF	☐	Other: _____

Note: Above referenced acronyms are defined below. [1]

Response:
The above referenced reports/certificates for all three Applicants are provided in Appendix 6.D.

E. Provide a copy of the following (as applicable):

☒ A copy of the related Quality Assurance plan
☒ Protocols for service
☒ Patient Selection Criteria/Intake form

Response:
All of the above referenced documents are provided in Appendix 6.E.

As to quality, the Program with JDH has monitored its outcomes since its inception. On a monthly basis the Program has an interdisciplinary case review for all Program physicians and clinicians to review individual angioplasty and open heart surgery cases for the purpose of shared learning and process improvements. The Program Joint Quality Committee meets every other month to discuss Program data, registry submission outcome reports and Program processes. Program physicians provide ongoing education and consultation to clinical staff as a means to continued learning.

As a result, the Program has successfully provided quality cardiac services during the three year demonstration project and will continue to produce outcome excellence. Outcomes measures demonstrate that advanced cardiac services provided are meeting or exceeding national registry benchmarks.

Angioplasty:

As to Angioplasty, the Program has consistently demonstrated outcomes in major areas that are comparable to or better than the national benchmarks. Of particular note is the Program's door to balloon time. The ACC in conjunction with a national quality group named the D2B Alliance (Appendix 6.E) has set a standard for hospitals that provide primary angioplasty. The standard is that a minimum of 75% of the patients presenting with STEMI should have their arteries opened or unblocked within 90 minutes of entering the emergency department. In Waterbury, if a STEMI patient is admitted to the

[1] DPH – Department of Public Health; JCAHO – Joint Commission on Accreditation of Hospitals Organization; AAAHC – Accreditation Association for Ambulatory Health Care, AAAASF – American Association for Ambulatory Surgery Facilities, Inc.

emergency department at either campus, 88% of the time the patient's arteries will be opened in less than 90 minutes. As of July 2008, the average door to balloon time for the Program was 67 minutes. This far exceeds the national benchmark and is due to the superb teamwork of the clinical staff and physicians. Angioplasty outcomes as reported to the ACC are noted in the Tables F, G and H below and encompass data from April 2007 to March 2008. All demonstrate the exceptional quality of the angioplasty services.

Table F Proportion of STEMI Patients with door to balloon time <= 90 Minutes

	April 07 to March 08	ACC Mean D2B <= 90 minutes
WH (381 cases)		
% D2B <= 90 minutes	83%	72%
SMH (245 cases)		
% D2B <= 90 minutes	93%	72%

Source: American College of Cardiology (ACC)

Table G Angiographic Success

	April 07 to March 08	ACC Mean Angiographic Success
WH (381 cases)		
Angiographic Success	99.6%	99.3%
SMH (245 cases)		
Angiographic Success	99.3%	99.3%

Source: American College of Cardiology (ACC)

Table H Risk Adjusted Mortality (RAM)

	April 07 – March 08	ACC Mean RAM
WH (381)		
Risk Adjusted Mortality	1.05%	1.23%
SMH (245 cases)		
Risk Adjusted Mortality	.067%	1.23%

Source: American College of Cardiology (ACC)

The Program has demonstrated the need for the services and the quality of the services provided. The community has demonstrated the confidence in and overwhelming support of the Program continuing to provide these necessary cardiac services.

Open Heart Surgery:

As noted previously, the Program has submitted data to the STS National Adult Cardiac Surgery Database since it began providing services. In addition to specific Program data, the STS also provides comparisons to other programs across the country. National Quality Forum measures identify key quality indicators for open heart surgery programs. The most recent STS Composite Quality Rating of these measures gives both SMH and TWH an excellent rating for overall quality and avoidance of morbidity and mortality for calendar year 2007. This rating is produced annually and demonstrates that the Program produces outcomes that meet or exceed the STS benchmarks. 77% of the programs reporting to the STS received similar ratings demonstrating that the services provided in Waterbury are comparable to those throughout the country. In 2007, 768 hospitals reported their open heart surgery data to the STS regarding over 200,000 procedures.

In addition, outcome data for the two major open heart surgery procedures that make up the majority of the open heart surgery volume are noted below and are compared to the most recent STS benchmark for the same outcome. All HCGW data compares favorably to the data in the STS database.

Table I **Open Heart Surgery Outcome Data**

TWH	2007	STS Benchmark
CABG (57 Cases)		
Inpatient Mortality	0%	1.8%
Deep Sternal Wound Infection	0%	0.3%
Post Operative Stroke	0%	1.1%
Aortic Valve Replacement (9 Cases)		
Inpatient Mortality	0%	2.5%
Deep Sternal Wound Infection	0%	0.4%
Post Operative Stroke	0%	1.6%

SMH	2007	STS Benchmark
CABG (69 Cases)		
Inpatient Mortality	1.4%	1.8%
Deep Sternal Wound Infection	0%	0.3%
Post Operative Stroke	1.3%	1.1%
Aortic Valve Replacement (6 Cases)		
Inpatient Mortality	0%	2.5%
Deep Sternal Wound Infection	0%	0.4%
Post Operative Stroke	0%	1.6%

Source: STS database 2007

7. Improvements to Productivity and Containment of Costs

In the past year have your facilities undertaken any of the following activities to improve productivity and contain costs?

- ☒ Energy conservation
- ☒ Group purchasing
- ☒ Reengineering
- ☐ None of the above
- ☒ Application of technology (e.g., computer systems, robotics, telecommunication systems, etc.)
- ☒ Other (identify): Inpatient pediatric program consolidation, staff reductions, pharmacy standardization and inventory control.

Response:

SMH and TWH routinely engage in efforts to improve productivity and contain costs. This has been accomplished by implementing programs, using process improvement and lean techniques, and looking at efforts to consolidate services at the two hospitals.

Energy Conservation:

Energy conservation programs and initiatives for improved environmental and cost efficiency have enabled SMH and TWH to reduce the impact of escalating inflationary energy costs. Renovations and changes in equipment have occurred to accommodate energy efficient fixtures/equipment.

Reengineering:

Process improvement and reengineering are a mainstay to each hospital's quality improvement program and efforts to provide cost effective services. These projects work to refine inefficient processes, eliminate redundant work and work arounds, which all lead to an increase in efficiency and improved quality and patient satisfaction.

Applications of Technology:

Investments have been made at both hospitals in various technological applications aimed at improving productivity. Clinical information systems, Picture Archiving and Communication Systems (PACS), and the updating of nursing call systems are just some of the examples of technology used to enhance the delivery of clinical care.

Other:

During the past year, approval was granted by the OHCA to consolidate the inpatient pediatric programs at both Waterbury hospitals into one unit that will be owned and operated by Connecticut Children's Medical Center at a Waterbury campus. In addition to the many past collaborative efforts, the pediatric project is yet another example of a collaborative arrangement among three hospitals and community physicians in order to maintain the high standard of care in the Waterbury community. This effort, like the others before it, will lead to improving the access to quality of care, but also greater efficiency for the health care delivery system in Waterbury.

Both hospitals have had to engage in staff reductions in the last several years. Such actions are difficult by necessary given the payer climate. Other actions to contain costs include pharmacy standardization and inventory control.

Group Purchasing:

Both hospitals are members of national group purchasing networks, which help to reduce costs based on purchase and volume contracts. Every effort is made to focus on utilization of supplies and on standardization of products. Both of these efforts are accomplished through staff involvement and monitoring.

8. Miscellaneous

A. Will this proposal result in new (or a change to) your teaching or research responsibilities?

☐ Yes ☒ No

If you checked "Yes," please provide an explanation.

B. Are there any characteristics of your patient/physician mix that makes your proposal unique?

☒ Yes ☐ No

If you checked "Yes," please provide an explanation.

Response:
This proposal is unique as it will replace a mature program with demonstrated quality outcomes with one that is equally successful under the direction of a new CON. The Program already has a proven track record of high utilization by the greater Waterbury area as well as excellent clinical results.

The number of cardiologists that live and practice in the greater Waterbury area is significant as they are key to a successful comprehensive cardiac care Program. Over the last three years, the number of community based dedicated cardiologists has grown from 14 to 17 and a new practice has opened (Naugatuck Valley Cardiology Associates-NVCC). For the angioplasty Program there are now 4 practicing interventional cardiologists.

In addition, over the last three years, greater Waterbury has added 4 cardiothoracic surgeons and 4 cardiac anesthesiologists to the physician mix. These loyal physicians came to the Waterbury area solely for the original implementation of the Program and remain committed to the Program in the future. What makes these physicians valuable is the fact that they have brought to this Program decades of experience and systems of care that have been utilized in other successful programs. In addition, each of the cardiothoracic surgeons provides surgical services not just at SMH and TWH, but also at JDH and HH. This is a clear example of where sufficient utilization should not be based upon the volume of one type of service at one location. But instead, sufficient utilization should be based on the total amount of services provided along with the consideration of the entire population served by physician groups and the Program.

There is currently no need to further recruit physicians for this Program to successfully meet community needs.

All physicians have demonstrated full involvement in the Program. This has been demonstrated by participation in all levels of community based education, ongoing education of the clinical staff, participation in hospital and Program events, radio and television appearances, and, most importantly, the delivery of "state of the art" care to the citizens of greater Waterbury.

The greater Waterbury population has been described in great detail in question 5.iii.b. in terms of risk factors for coronary heart disease. The prevalence of these risk factors speaks to the ongoing need for the availability of advanced cardiac care in this city.

What is not documented in scientific or demographic literature, but what is prevalent in greater Waterbury, is the outpouring of support and gratitude for HCGW over the first three years of the Program. The greater Waterbury community is made up residents with a significant amount of loyalty to both SMH and TWH as demonstrated in the market share statistics outlined earlier in the application. They live, work, worship and seek healthcare in this community because they are connected to this community. Over 12,000 letters of support have been signed by members of this community to date and it is likely that many more have been sent directly to OHCA and other State officials. On August 20, 2008, approximately 2,000 members of the community attended a rally in support of all the efforts to keep this Program operational. These intangible and often overlooked aspects of the population should be considered in this proposal because they are enormous factors. The role of the local hospitals is to serve the community - without the Program the HCGW cannot do this to the fullest.

9. Affiliation

a. Provide a copy of the agreement SMH and TWH have drafted or signed with JDH to act as a tertiary care hospital to the proposed cardiac services.

Response:
See Appendix 9.a.

b. Provide a copy of any and all agreements between the Applicants, including a signed collaboration agreement, related to the proposal. The collaboration agreement should include at a minimum a description of each Applicant's responsibilities, patient selection guidelines, provision of emergency transfers, joint quality assurance reviews and joint training.

Response:
See Appendix 9.b. All of the above are included in the Appendix except for those listed below.

Patient Selection Guidelines: Included in clinical protocols (Appendix 6.E).

Provision for emergency transfers:

There is no formal written agreement among the three Applicants as it pertains to provision of emergency transfers. Emergency transfers are made physician to physician and are handled via direct communication between physicians and the ambulance service. The three year history of the HCGW demonstration project has not dictated that formal agreements are necessary for this purpose.

c. Provide a detailed discussion on what role has JDH played in HCGW operation beyond the initial training of the staff and establishment of the protocols.

Response:
JDH has been an active and formal participant in administrative, clinical and quality activities for HCGW since July 2004. After the initial assistance and guidance in the development of the Program including input into protocols, staff training and equipment purchases, the relationship with JDH has evolved into a collegial partnership of shared learning. JDH continues to act in an advisory capacity in all aspects of the Program. In 2007 and 2008 our agreements and relationships were formally renewed and continue through this application process.

Clinical/Quality:

JDH provides cardiothoracic surgical services and perfusion services via contract. JDH's director of cardiology is a member of the HCGW Advisory Board and, as such, has been involved in review and discussion of quality data. Since Program implementation, the director has provided advice and direction for peer review.

JDH participates in joint clinical case discussions held monthly at one of the partner hospitals. The purpose of these case discussions is to review specific cases for clinical learning opportunities and for colleagues to share clinical perspectives. JDH's chief of cardiothoracic surgery is also the chief of cardiothoracic surgery for HCGW. The chief and his colleagues participate in regular case reviews and joint quality meetings with the HCGW team to review Program data, clinical processes and overall areas of improvement. The JDH and HCGW chief of perfusion also participates in these quality review committees. JDH personnel continue to provide guidance to the Program as it relates to new technology (i.e. Robotics), equipment (i.e. new balloon pumps), supplies and possible purchases related to these.

Administrative:

JDH Administration has membership on the HCGW Advisory Board providing advice, direction and feedback on programmatic issues. JDH has given guidance and assistance in the area of marketing the Program, and has been involved in CON discussions including several planning sessions regarding their ongoing support of this process.

d. Discuss in detail the responsibilities of JDH in the establishment of the proposed services at TWH and SMH and the operation of HCGW.

Response:
JDH has committed to supporting HCGW administratively and clinically. This relationship has grown and developed over the three years as the Program has matured. It remains strong and one of mutual support.

HCGW will continue to seek advice, guidance and direction on clinical and administrative issues and, as such, will have representation from JDH on its Advisory Board. The cardiothoracic surgeons and perfusion teams remain contracted with HCGW through 2009 with the ability to extend the agreements. The responsibilities of JDH in the establishment of the proposed services at SMH and TWH d/b/a HCGW will remain in place going forward.

e. Provide Board of Directors or governing body resolutions from **each** Applicant approving the proposal.

Response:
See Appendix 9.e.

10. Financial Information

a. Type of ownership: (Please check off all that apply)

☒	Corporation (Inc.)	☐	Limited Liability Company (LLC)
☐	Partnership	☐	Professional Corporation (PC)
☐	Joint Venture	☒	Other (Specify): State Agency- JDH

b. Provide the following financial information:

i) Please confirm that each of the Applicants involved in this proposal has filed its FY 2007, audited financial statements with OHCA, as required pursuant to Section 19a-644, C.G.S.

Response:
SMH submitted audited financial statement with OHCA, as required pursuant to Section 19a-644, C.G.S. in February 2008.

TWH submitted audited financial statement with OHCA, as required pursuant to Section 19a-644, C.G.S. in February 2008.

JDH submitted audited financial statement with OHCA, as required pursuant to Section 19a-644, C.G.S. in June 2008.

ii) Provide the cash equivalent balance of each Applicant at the date of submission of this application.

Response:
The cash equivalent balance for SMH as of July 2008 was $30,011,000.

The cash equivalent balance for TWH as of July 2008 was $33,553,132.

The cash equivalent balance for JDH as of July 2008 was $ -17,870,154.

iii) Provide a copy of the most recently completed internal monthly financial statement for each Applicant.

Response:
Completed internal monthly financial statements are in Appendix 10.b.iii.

11. Revenue, Expense and Volume Projections

a. Payer Mix Projection

Please provide both the current payer mix and the projected payer mix with the CON proposal for the Total Facility based on Gross Patient Revenue in the following reporting format for **SMH**, **TWH**, **HCGW** and **JDH**, separately:

Total SMH Description	Current Payer Mix	FY 2009 Projected Payer Mix	FY 2010 Projected Payer Mix	FY 2011 Projected Payer Mix
Medicare*	40.7%	40.7%	40.7%	40.7%
Medicaid* (includes other medical assistance)	21.3%	21.3%	21.3%	21.3%
TriCare (CHAMPUS)	0.2%	0.2%	0.2%	0.2%
Total Government Payers	62.2%	62.2%	62.2%	62.2%
Commercial Insurers*	33.1%	33.1%	33.1%	33.1%
Self-Pay	2.5%	2.5%	2.5%	2.5%
Workers Compensation	2.2%	2.2%	2.2%	2.2%
Total Non-Government Payers	37.8%	37.8%	37.8%	37.8%
Uncompensated Care	0%	0%	0%	0%
Total Payer Mix	100.0%	100.0%	100.0%	100.0%

*Includes managed care activity.

Total TWH Description	Current Payer Mix	FY 2009 Projected Payer Mix	FY 2010 Projected Payer Mix	FY 2011 Projected Payer Mix
Medicare*	46.7%	46.7%	46.7%	46.7%
Medicaid* (includes other medical assistance)	16.8%	16.8%	16.8%	16.8%
TriCare (CHAMPUS)	0%	0%	0%	0%
Total Government Payers	63.5%	63.5%	63.5%	63.5%
Commercial Insurers*	32.2%	32.2%	32.2%	32.2%
Self-Pay	2.9%	2.9%	2.9%	2.9%
Workers Compensation	1.4%	1.4%	1.4%	1.4%
Total Non-Government Payers	36.5%	36.5%	36.5%	36.5%
Uncompensated Care	0%	0%	0%	0%
Total Payer Mix	100.0%	100.0%	100.0%	100.0%

*Includes managed care activity.

Total JDH Description	Current Payer Mix	FY 2009 Projected Payer Mix	FY 2010 Projected Payer Mix	FY 2011 Projected Payer Mix
Medicare*	39.5%	39.5%	39.5%	39.5%
Medicaid* (includes other medical assistance)	11.9%	11.9%	11.9%	11.9%
TriCare (CHAMPUS)	0.3%	0.3%	0.3%	0.3%
Total Government Payers	51.7%	51.7%	51.7%	51.7%
Commercial Insurers*	45.8%	45.8%	45.8%	45.8%
Self-Pay	0.3%	0.3%	0.3%	0.3%
Workers Compensation	1.2%	1.2%	1.2%	1.2%
Total Non-Government Payers	47.3%	47.3%	47.3%	47.3%
Uncompensated Care	1.0%	1.0%	1.0%	1.0%
Total Payer Mix	100.0%	100.0%	100.0%	100.0%

*Includes managed care activity.

Response:
HCGW Inc. as an entity is the administrative arm of the Heart Center Program. It is not, in and of itself, an organization that provides patient care. Therefore, it does not generate patient revenue or have a payer mix.

b. Provide the following for **SMH**, **TWH**, **HCGW**, **JDH** and the **parent corporations**, regarding the financial projections:

i) A summary of revenue, expense and volume statistics, with the CON project, without the CON project and incremental to the CON project. **See attached.**

Response:
Please see Appendix 11.b.i. and Appendix 11.c.i. HCGW, Inc. does not provide patient care therefore this question does not apply. HCGW financials are provided in Appendix 11.c.i.

ii) As an addendum to your completed financial attachments as provided in 11b(1), for **each** Applicant (by facility and total system) provide a break out of the financial expenses and revenues by service (i.e. Primary Angioplasty, Elective Angioplasty and Open Heart Surgery).

Response:
Please see Appendix 11.b.i. Financial Attachment II.

iii) The assumptions utilized in developing the projections (e.g., FTE's, volume statistics, other expenses, revenue and expense % increases, project implementation date, etc.).

Response:

For TWH the overall assumptions utilized in developing projection are as follows:

- Salaries and fringe benefits will increase 3.5%
- Professional and contracted services will increase 4%
- Net patient revenue will increase 4%
- Supplies and drugs will increase 5%
- Bad debt will increase 3%
- Other operating expenses will increase 3%
- Non operating revenue will increase 3%
- Case volume was held constant
- FTE's will remain flat
- In order to mitigate operating losses for FY 2009, TWH Management Team will be engaging an independent consultant group to work with management on improving revenues and reducing expenses. We conservatively estimated a $5 million improvement in revenue and a $3 million improvement in expenses.

For SMH the overall assumptions utilized in developing projections are as follows:

- Salaries and Fringe benefits will increase 3.5%
- Net Patient revenues will increase 4%
- Supplies and non-salary expenses will increase 5%
- Case volume was held constant
- FTE's will remain flat

For JDH the overall assumptions utilized in developing projections are as follows:

- FTEs will increase 1% in FY 09, 0% in FY 10 and FY 11 based on inpatient growth. FTEs will increase to maintain FTE per adjusted occupied bed equal to 4.2.
- Inpatient Volume will increase will be 0%
- Outpatient Volume will increase will be 5%
- Net revenue will increase 2% per unit assumption
- Salaries, Wages and Fringe Benefits will increase 4.5% per year
- Expense inflation rate will increase 3% per year
- Since HCGW has been fully operational for three years, JDH is not assuming any incremental increases in angioplasty, open heart services, or cardiac catheterizations as a result of the project. In addition JDH is not assuming there will be any inpatient transfers from SMH or TWH.

iv) Provide a description of the additional staff, equipment, and supplies (including drug-eluting stents) required to provide the proposed services. Include a description of the availability of cardiac interventionalists, cardiac surgeons, nurses

and anesthesiologists.

Response:
To continue to provide advanced cardiac services at SMH and TWH there will be no additional staff, equipment or renovations needed as the investment for these key components of the Program were accounted for in the start up phase of the Program. All clinical areas are appropriately equipped and staffed and are currently providing services. Stents are an operational expense and have been considered along with all necessary patient supplies in the financial projections. Drug eluting and bare metal stents currently account for approximately 45% of the patient chargeable items line in a cardiology department budget.

Although no additional start up expenses will be incurred, there will be a significant financial impact should the proposal not be approved. SMH and TWH have been classified as financially distressed by the State of Connecticut for several years and continue to be so. Since the inception of services in July 2005, capital investment in the Program was approximately $7 million dollars, a sizeable sum. Hospitals typically have several years to utilize invested resources of this magnitude to the fullest and to depreciate the cost on their financial statements.

If the Program is not continued under the direction of a new CON it will have a dramatic negative financial impact on both SMH and TWH. The combined loss of net revenue from angioplasty, open heart surgery and a significant number of cardiac catheterizations will reach at least $20 million annually. Even after adjusting for a reduction in approximately $10 million of direct expenses, the combined impact to both hospitals would be approximately $10 million annually. These figures are conservative and as such do not include loss of patients with other cardiac diagnoses who would choose or would be referred by their physicians to facilities able to provide a full complement of advanced cardiac services. It also does not include the full array of outpatient cardio-pulmonary services that would also be impacted.

Further, the financial impact of ceasing the Program would cause the likely closure of other unprofitable medical services operated by SMH and TWH. As major employers in the City of Waterbury, the financial viability of the hospitals is critical to the overall economic health of the region. In recent testimony before the Department of Economic and Community Development, Stephen Frayne, Senior Vice President of Health Policy for the Connecticut Hospital Association discussed the economic impact provided by hospitals (Appendix 11.b.iv). Mr. Frayne testified that hospitals statewide generate $12.2 billion per year for state and local economies. In greater Waterbury, with two local hospitals, this impact is of economic significance.

Absent a Program in Waterbury, there would be an inherent increase in costs transferred to patients and families in the greater Waterbury area for items such as transportation, duplicative co-pays from a second hospital admission, lost work,

childcare fees and travel expenses to name a few. The full financial impact with and without the Program are demonstrated in the financial tables.

Availability of Physicians and professional staff:

As noted in questions 6.C and 8 B. the Program maintains a large staff of physicians and professional staff who are committed to providing care to greater Waterbury residents. The greater Waterbury community is fortunate to have a group of physicians and staff of such quality and dedication to the Program. No addition physician recruitment is necessary.

v) An explanation for any incremental losses (Historical and Projected) by service (i.e. Primary Angioplasty, Elective Angioplasty and Open Heart Service).

Response:
As per Appendix 11.b.i, the Program has not had incremental losses historically and as per Appendix 11.b.vi, the Program is not projected to have incremental losses.

vi) Please complete the enclosed, OHCA's **Financial Attachment II,** for SMH, TWH, and JDH.

Response:
Please see Appendix 11.b.vi.

HEART
CENTER
of Greater Waterbury

An Introduction to the Heart Center of Greater Waterbury

The Heart Center of Greater Waterbury is an advanced cardiac care program offering the greater Waterbury community the ability to have all types of heart care services at both Saint Mary's Hospital and Waterbury Hospital.

The program builds upon a strong foundation of heart services, including the catheterization labs available at both hospitals, and the complementary services provided by our emergency departments and intensive care units. By adding the ability to perform advanced cardiac procedures, patients will now receive full cardiac services without having to leave Waterbury. With the creation of the Heart Center, patients in need of cardiac treatment will be cared for at either hospital by their private physician.

The cardiologist who provide these services are among the most experienced in Connecticut, having already performed thousands of cardiac procedures for Waterbury patients. They have established a strong track record of quality care and positive patient outcomes.

Saint Mary's and Waterbury Hospital in conjunction with the University of Connecticut Health Center/John Dempsey Hospital in Farmington have brought the knowledge of their cardiothoracic surgeons to Waterbury in the event that a patient requires cardiac surgery.

These same surgeons perform life-saving cardiac procedures each day for patients at UConn Health Center and Hartford Hospital. Now, they have brought their experience and expertise to Waterbury, so cardiac patients here can receive the comprehensive care they need and deserve close to home.

The Heart Center of Greater Waterbury provides a full continuum of care, which begins with education and awareness, continues through diagnosis and treatment, and finally the rehabilitation needed to complete the healing process. All of the services in this continuum are available to patients at both Saint Mary's Hospital and Waterbury Hospital. It's the quality care you need where you need it – close to home.

BASICS OF HEART DISEASE

HEART DISEASE RISK FACTORS

Risk Factors You Can Change

- ♥ High blood cholesterol
- ♥ High blood pressure
- ♥ Smoking
- ♥ Your stress level
- ♥ Being overweight
- ♥ Diabetes

Risk Factors You Can't Change

- ♥ Your age
- ♥ Your sex
- ♥ Your family medical history

HOW HEART DISEASE DEVELOPS

Heart Disease occurs when a process called arteriosclerosis clogs or blocks the coronary arteries. Your coronary arteries are the pipes that supply your heart with oxygen-rich blood it needs.

The Process of Arteriosclerosis

- ♥ Medical conditions, bad habits and other factors damage the walls of the coronary arteries. Cholesterol and other fatty substances in the blood collect on the damaged artery walls.

- ♥ The fatty substances build up layer upon layer and form a hard substance called plaque.

- ♥ Plaque build-up narrows the arteries reducing or blocking the flow of blood to the heart.

HEART CENTER
of Greater Waterbury

CLASSIC SIGNS OF A HEART ATTACK

Heart attacks can sneak up on you. Your best defense is knowledge about what to look for.

Take these signs seriously:

Sudden, intense pressure (as if an elephant were sitting on your chest), squeezing, fullness, tightness, burning or pain in the chest that lasts more than a few minutes.

Chest pain that travels to the arm, neck, jaw, inside arm, shoulder (left side more than right), upper abdomen (often mistaken for indigestion pain) or back between the shoulder blades. Pain may be continuous or may come and go.

Chest discomfort and feeling lightheaded.
Shortness of breath, dizziness
Fainting
Sweating
Nausea
Vomiting
Unexplained tiredness (mostly in women)

CHOLESTEROL

THE GOOD -

HDL - 40 or greater Desirable
Under 40 Not desirable

HDL (High Density Lipoprotein) is known as "good" cholesterol. HDL cholesterol actually contains very little cholesterol in its core. As it travels through the bloodstream it carries LDL or "bad" cholesterol away from the arteries to the liver where it is either recycled or removed from the body.

THE BAD -

LDL – Under 100 Desirable for those at high risk
Under 130 Desirable
130 – 159 Borderline high
160 or greater High

LDL (Low Density Lipoprotein) is called the "bad" cholesterol. The core of the LDL is almost all cholesterol. If LDL levels are high, as it travels through the blood stream, it builds up on the artery walls. When LDL cholesterol combine with other substances, a plague like substance is produced that can clog the arteries.

THE UGLY -

Triglyceride – Under 150 Normal
150 – 199 Borderline High
200 – 499 High
500 or higher Very High

Triglyceride is a form of fat found in food, body fat, and is also carried in the blood as part of the cholesterol molecule. The visible fat on chicken or steak is actually triglycerides. If you are over weight, your body stores the extra calories you eat as triglycerides. People with high triglyceride levels often have low HDL or "good" cholesterol levels and this combination is considered by many experts to be associated with an increase risk of heart disease.

EXERCISE: WHAT'S IN IT FOR ME?

Quite a lot! Exercise is a small investment that reaps big benefits. Exercise can:

- ♥ Help you loose weight
- ♥ Tone your muscles
- ♥ Help you sleep
- ♥ Reduce stress
- ♥ Enhance your self-esteem
- ♥ Help reduce high blood pressure

The Basics of Heart Health Exercise

Here is the basic tenet of our exercise philosophy: Whatever you do is better than doing nothing at all. You need to understand three types of exercise that will strengthen your body in different ways:

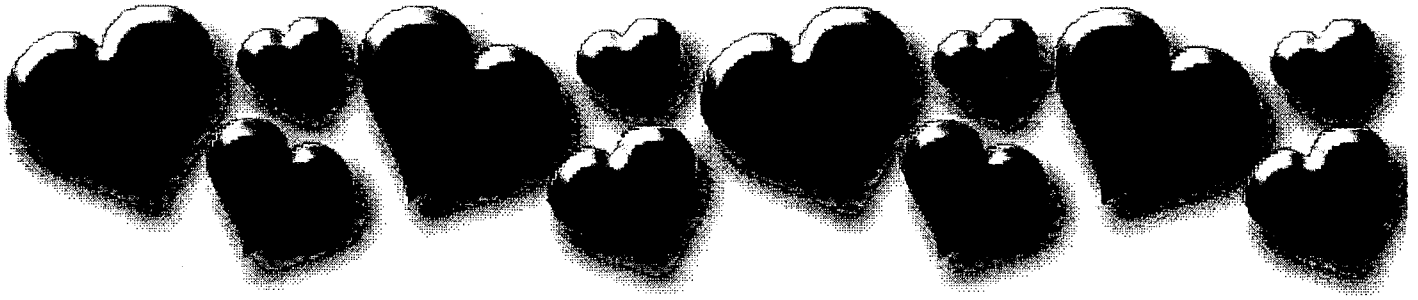
Aerobic Exercise – This type of exercise is vital if you want to improve the functioning of your cardiovascular system, which includes your heart. Aerobic exercise also improves your endurance and strengthens your musculoskeletal system, the bony skeleton of your body and the muscles attached to it. Aerobic exercise makes use of rhythmic, repetitive exercises that use large muscle groups.

Weight-Bearing Exercise – As a woman, you especially need to incorporate weight –bearing exercises into your daily life. Aerobic exercise is marvelous for the cardiovascular system, but alone does not help prevent the loss of bone mineral, which, as you age, can result in osteoporosis. Weight-bearing exercises are those that provide impact on the joints and, in doing so, stimulate the ends of your bones.

There are ways to build in weight-bearing exercise into your activity. One is by choosing aerobic activities that apply some force to the bones. Swimming provides aerobic exercise but, because your body is suspended weightless in the water, there is no force to your bones. Walking, jogging, aerobic dancing, and racquet sports qualify as both aerobic and weight-bearing activities.

Anaerobic Exercise (Strength Resistance Training)

Women especially should be aware of the need to keep the strength in their upper arms. Women tend to focus on their hips and thighs, but as we age, we need to build up our arms. This enables us carrying packages more easily, for example, and keeps the skin on our arms.



A good way to strengthen your upper body is to work out with weights. A simple exercise using dumbbells or other weights will accomplish your goal.

If you have heart disease, you must consult with your doctor before starting a new exercise program. As you start or increase your level of activity, if you experience any symptoms as chest pain, shortness of breath, dizziness or under fatigue, consult your doctor.

Before beginning activity, you should take a medical "inventory" of yourself. Recall any injuries or problems with your back, ankles arms or legs you may have suffered. Make certain that the activities you choose will not damage, but instead strengthen, these problem areas. Research shows that higher rates of injury are associated with weight-bearing activities like jogging and running. Those most likely to injure them selves are people who run for long distances, have a personal history of injury, or suddenly increase their exercise schedule.

What is Diabetes?

Our bodies use the food we eat to make the sugar we need for energy. Insulin helps the sugar leave the blood And go into our blood cells, where it is used as a kind of fuel. When this happens the way it should, the level of sugar in the blood goes down and our bodies have the energy for a full and active life.

In people with diabetes, this system doesn't work. When you have diabetes, your body can't make energy from the food you eat. Sugar stays in the blood instead of going in to the cells of the body.

Diabetes is a lifelong disease

What is pre-diabetes?

Prediabetes is a condition that comes before diabetes. It means that the blood sugar levels are higher than normal but are not high enough to be called diabetes.

If you have pre-diabetes, it means

You might get type 2 diabetes soon or sometime down the road

You are also more likely to get heart disease or have a stroke.

The way to delay or prevent type 2 diabetes is to have regular physical activity such as walking every day, lose weight and have a healthy diet.

KEEP TABS ON YOUR HEALTH

Regular testing tells you and your healthcare provider how well your Action Plan is working. Here are some tests he or she may want you to have:

Blood sugar. One of the most important tests in helping manage your diabetes you do yourself. This is the blood–sugar reading that you may take several times a day. Your healthcare provider will tell you how often to test your blood sugar.

Often your home tests show blood sugar levels that are about 10% lower than found in lab tests. So, it is important to also have your blood sugar tested by your healthcare provider.

Hemoglobin A1c. This blood test shows the blood sugar levels that you average over the past two to three months. A1c tests give the "big picture" of diabetes. A1c tests are usually done in a lab. The American Diabetes Association (ADA) advises people with type 2 diabetes to get an A1c test at least twice a year. You need your level checked more often if you are not at your goal or if your therapy changes.

Microalbuminuria. At last once a year, your healthcare provider will test for protein in your urine. A positive test may mean that your kidneys have been damaged by diabetes or blood pressure. Fever and exercise can raise the protein in your urine short-term; your healthcare provider may want to repeat the test. He or she may prescribe high blood pressure medicine(s).

Cholesterol. Substance in your blood, called cholesterol and triglycerides, should be tested at least once a year to help prevent heart disease. You want your LDL cholesterol to be less than 100 mg/dL. This should even be lower, if you have had a heart attack and have diabetes. You want your HDL cholesterol to be over 40 for men and over 50 mg/dL for women. If you can't control your cholesterol with diet and exercise your doctor should provide medicine.

Blood pressure. Your blood pressure should be tested every time you visit your healthcare provider. People with diabetes should try to keep their blood pressure below 130/80 mm Hg. High blood pressure can cause heart disease, eye disease, stroke, and kidney disease. Again, your healthcare provider may prescribe medicine if your blood pressure doesn't come down with diet and exercise.

Feet. You should check your feet daily for calluses, bunions, sores, or discolored skin. These can lead to infections or ulcers, and, in people with severe nerve disease they can lead to amputations. Your healthcare provider should do a complete exam at least once a year. Also, keep your toenails short. Long nails may cause friction and lead to hidden ulcers in between your toes.

Eyes and teeth. Get an eye exam at least once a year. Ask a dentist to check your teeth and gums every six months.

Daily Meal Planning Guide

When you find out you have diabetes there are so many things to learn! One of the first things you may want to know is – what can I eat? Choosing healthy foods can help you control your blood glucose. A daily meal plan is an important part of your diabetes management, along with physical activity, blood glucose checks, and often diabetes medications.

There is no one meal plan that works for everybody with diabetes. This guide will provide you with three ways that may help you plan your meals.

- *Balance Your Plate:* Many people with diabetes like to keep meal planning simple. This food plan can help you to easily portion out your food.
- *Food List for Meal Planning* and *Personal Meal Plan:* If you want to count servings of food and follow a plan that is good for your diabetes too, check out the *Food List for Meal Planning* and the *Personal Meal Plan.* This plan will help you know how much of carbohydrate, protein, and fat you can eat each day.
- *Carbohydrate Counting:* There are many carbohydrate foods to enjoy, including grains, fruits, vegetables, milk products and those with sugar. Carbohydrate foods raise your blood glucose level more than proteins and fats. This meal planning approach helps you to keep track of how much carbohydrate you eat at your meals and snacks. Many people who take insulin like to use this plan.

Some key things to remember no matter which meal plan you choose to follow:

- Keep your food intake consistent from day to day
- Make half your grains whole grains
- Choose whole fruits and vegetables often
- Go with lean protein
- Get your calcium-rich foods
- Know your limits on fats, salt, and sugars
- Choose water instead of sugary beverages, juice "drinks", and sports drinks

Checking your blood glucose will help you to see how your food choices affect your blood glucose control.

A Registered Dietitian (RD) can help you make a meal plan that best meets your needs and lifestyle. Ask your healthcare provider, diabetes educator, hospital, or local diabetes association for the names of RDs in your area who work with people that have diabetes.

Lilly

Meal Planning Options

Balance Your Plate

One fruit serving is 1 small fresh fruit, 2 Tbs. dried fruit, or ½ cup canned fruit or unsweetened fruit juice.

Fill this ¼ of the plate with a starch, grain, or starchy vegetable, such as corn, peas or potatoes.

Use fat-free/low-fat milk and milk products.

Fill this ½ of the plate with non-starchy vegetables, such as broccoli, carrots, cauliflower, or green beans.

Fill this ¼ of the plate with lean meat, poultry or fish. If you choose a plant-based protein, such as dried beans, consider the carbohydrate content as part of your total carbohydrate amount for the meal.

Practical Nutrition: The Idaho Plate Method Practical Diabetol 1998;17:42-45.

Try your hand at these guidelines for estimating portion sizes*:

Your palm, not including fingers and thumb, is about 3 ounces of cooked and boneless meat.

A fist is about 1 cup or about 30 grams of carb for foods such as 1 cup ice cream or 1 cup cooked cereal.

Your thumb is about 1 tablespoon or 1 serving of regular salad dressing, reduced-fat mayonnaise or reduced-fat margarine.

Your thumb tip is about 1 teaspoon or 1 serving of margarine, mayonnaise or other fats such as oils.

These portion estimates are based on a woman's hand size. Hand sizes vary.
Measuring or weighing foods is the most accurate way to figure out a portion size.

Food List for Meal Planning

Key

* Foods marked with * should be counted as 1 starch + 1 fat per serving

☺ Foods marked with ☺ contain more than 3 grams of dietary fiber per serving

! Foods marked with ! contain 480 mg or more of sodium per serving

oz= ounce
tsp= teaspoon
Tbsp= Tablespoon

Resources:
Choose Your Foods: Exchange Lists for Diabetes, American Diabetes Association and American Dietetic Association, 2007.
Beyond Rice and Beans by Lorena Drago (American Diabetes Association, 2006)

Starch

Each serving from this list contains **15 grams carbohydrate,** 0-3 grams protein, 0-1 gram fat and 80 calories.

These foods are the cornerstone of a healthy eating plan. Most of their calories come from carbohydrate, a good source of energy. Many foods from this group also give you fiber, vitamins and minerals. Prepare and eat starchy foods with as little added fat as possible. Choose whole grain starches as often as you can.
In general, a single serving of starch is:

- ½ cup of cooked cereal, grain or starchy vegetable
- ⅓ cup of cooked rice or pasta
- 1 oz of a bread product such as 1 slice of whole wheat bread
- ¾ to 1 oz of most snack foods (some snack foods may also have extra fat)

Bread	**Serving Size**
Bagel, large (about 4 oz)	¼ (1 oz)
*Biscuit, 2 ½ inches across	1
Bread (whole wheat, white or rye)	1 slice (1 oz)
*Cornbread	1 ¾ inch cube (1 ½ oz)
English muffin	½
Hot dog or hamburger bun	½ (1 oz)
Pancake	4 inches across, ¼ inch thick (1)
Pita pocket bread (6" across)	½
Roll, plain, small	1 (1 oz)
Tortilla, corn or flour (6" across)	1
*Waffle	4 inch square or 4 inches across (1)

Cereals and Grains	**Serving Size**
Cereals, cooked (oats, oatmeal)	½ cup
Cereals, unsweetened, ready-to-eat	¾ cup
Couscous	⅓ cup
Granola, low-fat	¼ cup
Pasta, cooked	⅓ cup
Rice, white or brown, cooked	⅓ cup

Starchy Vegetables	**Serving Size**
Breadfruit	¼ cup small cubes
Corn, cooked	½ cup
Corn on cob, large	½ cob (5 oz)
☺ Hominy, canned	¾ cup
☺ Peas, green, cooked	½ cup
Plantain, ripe	⅓ cup
Potato	
baked with skin	¼ large (3 oz)
boiled, all kinds	½ cup or ½ medium (3 oz)
* mashed with milk and fat	½ cup
French fried (oven-baked)	1 cup (2 oz)
Spaghetti/pasta sauce	½ cup
☺ Squash, winter (acorn, butternut)	1 cup
Yam, sweet potato, plain	½ cup
Yucca	⅓ cup

Crackers and Snacks	**Serving Size**
Crackers	
*round, butter-type	6
saltines	6
Graham cracker, 2 ½ inch square	3
Popcorn	
* ☺ with butter	3 cups
☺ lower fat or no fat added	3 cups
Pretzels	¾ oz
Snack chips (tortilla chips, potato chips)	
fat-free or baked	15-20 (¾ oz)
* regular	9-13 (¾ oz)

Beans, Peas and Lentils (Count as 1 Starch + 1 Lean Meat)	**Serving Size**
☺ Baked beans	⅓ cup
☺ Beans, cooked (black, garbanzo, kidney, lima, navy, pinto, white)	½ cup
☺ Lentils, cooked (brown, green, yellow)	½ cup
☺ Peas, cooked (black-eyed, split)	½ cup

Fruits

Each serving from this list contains **15 grams carbohydrate,** 0 grams fat, 0 grams protein and 60 calories.

Fruits are good sources of fiber, regardless if they are fresh, frozen, or dried. Fruit juices contain very little fiber. Choose fruits instead of juices whenever possible. When using canned fruit, choose fruit packed in its own juice or light syrup.

In general, a single serving of fruit is:
- ½ cup of canned or fresh fruit or unsweetened fruit juice
- 1 small fresh fruit (4 oz)
- 2 tablespoons of dried fruit

Fruit	**Serving Size**
Apple, unpeeled, small	1 (4 oz)
Applesauce, unsweetened	½ cup
Banana, extra small	1 (4 oz)
Berries	
☺ Blackberries	¾ cup
Blueberries	¾ cup
☺ Raspberries	1 cup
☺ Strawberries	1 ¼ cup whole berries
Cantaloupe, small	⅓ melon or 1 cup cubed (11 oz)
Cherries, sweet fresh	12 (3 oz)
Dried fruits (blueberries, cherries, cranberries, mixed fruit, raisins)	2 Tbsp
Grapefruit, large	½ (11 oz)
Grapes, small	17 (3 oz)
Guava	½ cup
☺ Kiwi	1 (3 ½ oz)
Mandarin oranges, canned	¾ cup
Mango, small	½ fruit (5 ½ oz) or ½ cup
☺ Orange, small	1 (6 ½ oz)
Papaya	½ fruit or 1 cup cubed (8 oz)
Passion fruit	¼ cup
Peaches (fresh, medium)	1 (6 oz)
Pears (fresh, large)	½ (4 oz)
Pineapple (fresh)	¾ cup
Plums	
dried (prunes)	3
small	2 (5 oz)
Tamarind	¼ cup whole or 1 oz dried
Watermelon	1 slice or 1 ¼ cups cubes (13 ½ oz)

Fruit Juice	**Serving Size**
Apple, grapefruit, orange, pineapple	½ cup
Fruit juice blends, 100% juice, grape juice, prune juice	⅓ cup

Milk

Milk and yogurt are rich in calcium and protein. Choose fat-free, low-fat and reduced-fat varieties for health. They have less saturated fat and cholesterol than whole milk products.

Fat-free (skim) or low-fat (1%) milk and yogurt: Each serving from this list contains **12 grams carbohydrate,** 8 grams protein, 0-3 grams fat and 100 calories.

Milk, buttermilk, acidophilus milk, Lactaid	1 cup
Evaporated milk	½ cup
Yogurt, plain or flavored with a low calorie sweetener	⅔ cup (6 oz)

Reduced-fat (2%) milk and yogurt: Each serving from this list contains **12 grams carbohydrate,** 8 grams protein, 5 grams fat and 120 calories.

Milk, acidophilus milk, kefir, Lactaid	1 cup
Yogurt, plain	⅔ cup (6 oz)

Whole milk and yogurt: Each serving from this list contains **12 grams carbohydrate,** 8 grams protein, 8 grams fat and 160 calories.

Milk, buttermilk, goat's milk	1 cup
Evaporated milk	½ cup
Yogurt, plain	8 oz

Dairy-Like Foods	**Serving Size**
Chocolate milk	
fat-free (1 fat-free milk + 1 carbohydrate)	1 cup
whole (1 whole milk + 1 carbohydrate)	1 cup

Food List for Meal Planning

Smoothies, flavored, regular *(1 fat-free milk + 2 ½ carbohydrate)*	10 oz
Soy milk, regular, plain *(1 carbohydrate + 1 fat)*	1 cup
Yogurt	
juice blends *(1 fat-free milk + 1 carbohydrate)*	1 cup
with fruit, low-fat *(1 fat-free milk + 1 carbohydrate)*	⅔ cup (6 oz)

Sweets, Desserts, and Other Carbohydrates

Each serving from this list contains **15 grams of carbohydrate;** the amount of protein, fat and calories varies. You can substitute food choices from this list for other carbohydrate-containing foods (such as those found on the Starch, Fruit or Milk lists) in your meal plan, even though these foods have added sugars or fat. The foods on this list do not have as many vitamins, minerals and fiber. Choose foods from this list less often if you are trying to lose weight. Many sugar-free, fat-free and reduced-fat products are made with ingredients that contain carbohydrate, so check the Total Carbohydrate information on the Nutrition Facts food label.

Food	**Serving Size**
Brownie, small, unfrosted *(Count as 1 carbohydrate + 1 fat)*	1 ¼ inch square, ⅞ inch high (about 1 oz)
Cake	
frosted *(Count as 2 carbohydrates + 1 fat)*	2-inch square (about 1 oz)
unfrosted *(Count as 1 carbohydrate + 1 fat)*	2-inch square (about 1 oz)
Candy bar, chocolate/peanut *(Count as 1 ½ carbohydrates + 1 ½ fats)*	2 "fun size" bars (1 oz)
Candy, hard	3 pieces
Cookies	
chocolate chip *(Count as 1 carbohydrate + 2 fats)*	2 cookies (2 ¼ inch across)
vanilla wafer *(Count as 1 carbohydrate + 1 fat)*	5 cookies
Doughnut, cake, plain *(Count as 1 ½ carbohydrates + 2 fats)*	1 medium (1 ½ oz)
Flan (caramel custard) *(Count as 2 carbohydrates)*	½ cup
Fruit juice bars, frozen, 100% juice	1 bar (3 oz)
Gelatin, regular	½ cup
Granola or snack bar, regular or low-fat *(Count as 1 ½ carbohydrates)*	1 bar (1 oz)
Hot chocolate, regular *(Count as 1 carbohydrate + 1 fat)*	1 envelope added to 8 oz water
Ice cream	
light and no sugar added *(Count as 1 carbohydrate + 1 fat)*	½ cup
regular *(Count as 1 carbohydrate + 2 fats)*	½ cup
Jam or jelly, regular	1 Tbsp
Muffin (4 oz) *(Count as 1 carbohydrate + ½ fat)*	¼ muffin (1 oz)
Pie, commercially prepared fruit, 2 crusts *(Count as 3 carbohydrates + 2 fats)*	⅙ of 8-inch pie
Pudding	
regular (made with reduced-fat milk) *(Count as 2 carbohydrates)*	½ cup
sugar-free or sugar- and fat-free (made with fat-free milk)	½ cup
Sports drink	1 cup (8 oz)
Sugar	1 Tbsp
Syrup	
light (pancake type)	2 Tbsp
regular (pancake type)	1 Tbsp
Yogurt, frozen, fat-free	⅓ cup

Nonstarchy Vegetables

Each serving from this list contains **5 grams carbohydrate,** 2 grams protein and 25 calories. You should try to eat at least 2 to 3 nonstarchy vegetable servings each day. Choose a variety of vegetables to benefit from their important vitamins, minerals and antioxidants. When using canned vegetables, choose no salt added versions or rinse regular canned vegetables. In general, a single serving of a nonstarchy vegetable is:

- ½ cup of cooked vegetables or vegetable juice
- 1 cup of raw vegetables

Amaranth or Chinese spinach
Beans (green, wax, Italian)
Bean sprouts
Broccoli
Cabbage (green, bok choy, Chinese)
☺ Carrots
Cauliflower
Celery
Cucumber
Eggplant
Greens (collard, kale, mustard, turnip)
Jicama
Mushrooms, all kinds, fresh
Okra
Onions
Pea pods
☺ Peppers (all varieties)
Radishes
! Sauerkraut
Spinach
Squash (summer, crookneck, zucchini)
Tomatoes, fresh and canned
! Tomato sauce
! Tomato/vegetable juice
Water chestnuts

Meat and Meat Substitutes

Meat and meat substitutes are rich in protein. Whenever possible, choose lean meats. Portion sizes on this list are based on cooked weight, after bone and fat have been removed. The carbohydrate content varies among plant-based proteins, so read food labels carefully.

Lean meats and meat substitutes: Each serving from this list contains **0 grams carbohydrate,** 7 grams protein, 0-3 grams fat and 45 calories.

Beef: Select or Choice grades: ground round, roast (chuck, rib, rump), round, sirloin, steak (cubed, flank, porterhouse, T-bone), tenderloin	1 oz
Cheeses with 3 grams of fat or less per oz	1 oz
Cottage cheese	¼ cup
Egg whites	2
Fish, fresh or frozen, plain: catfish, cod, flounder, haddock, halibut, orange roughy, salmon, tilapia, trout, tuna	1 oz
Hot dog with 3 grams of fat or less per oz	1
Pork, lean	
Canadian bacon	1 oz
Rib or loin chip/roast, ham, tenderloin	1 oz
Poultry, without skin	1 oz
Processed sandwich meats with 3 grams of fat or less per oz	1 oz
Tuna, canned in water or oil, drained	1 oz

Medium-fat meat and meat substitutes: Each serving from this list contains **0 grams carbohydrate,** 7 grams protein, 4-7 grams fat and 75 calories.

Beef: corned beef, ground beef, meatloaf, Prime grades trimmed of fat (prime rib)	1 oz
Cheeses with 4-7 grams of fat per oz: feta, mozzarella, pasteurized processed cheese spread, reduced-fat cheeses, string cheese	1 oz
Egg	1
Fish, any fried product	1 oz
Pork, cutlet, shoulder roast	1 oz
Poultry, with skin or fried	1 oz
Ricotta cheese	2 oz or ¼ cup
! Sausage with 4-7 grams of fat per oz	1 oz

High-fat meat and meat substitutes: Each serving from this list contains **0 grams carbohydrate,** 7 grams protein, 8+ grams fat and 100 calories.

Bacon	
! pork	2 slices
! turkey	3 slices
Cheese, regular: American, bleu, brie, cheddar, hard goat, Monterey jack, queso and swiss	1 oz
*! Hot dog: beef, pork or combination	1
Pork spareribs	1 oz
Processed sandwich meats with 8 grams of fat or more per oz: bologna, pastrami, hard salami	1 oz

! Sausage with 8 grams fat or more per oz: bratwurst, chorizo, Italian, knockwurst, Polish, smoked, summer	1 oz

Plant-based proteins: Each serving from this list contains 7 grams protein and a **variable amount of carbohydrate,** fat and calories. Beans, peas and lentils are also found on the Starch list. Nut butters in smaller amounts are found in the Fats list.

Food	**Amount**
Beans, lentils, or peas (cooked) *(Count as 1 starch + 1 lean meat)*	½ cup
☺Hummus *(Count as 1 carbohydrate + 1 high-fat meat)*	⅓ cup
Nut spreads: almond butter, cashew butter, peanut butter, soy nut butter *(Count as 1 high-fat meat)*	1 Tbsp
Tempeh *(Count as 1 medium-fat meat)*	¼ cup
Tofu *(Count as 1 medium-fat meat)*	4 oz (½ cup)

Fats

Each serving from this list contains **0 grams carbohydrate,** 0 grams protein, 5 grams fat and 45 calories.

Choose heart-healthy fats from the monounsaturated and polyunsaturated groups more often. In general, a single serving of fat is:

- 1 teaspoon of regular margarine, vegetable oil or butter
- 1 tablespoon of regular salad dressing

Unsaturated Fats

Monounsaturated Fats	**Serving Size**
Avocado, medium	2 Tbsp (1 oz)
Nut butters (*trans*-fat free)	1 ½ tsp
Nuts	
almonds, cashews	6 nuts
macadamia	3 nuts
peanuts	10 nuts
pecans	4 halves
Oil: canola, olive, peanut	1 tsp
Olives, black (ripe)	8 large
Olives, green (stuffed)	10 large

Polyunsaturated Fats	**Serving Size**
Margarine	
lower-fat spread	1 Tbsp
stick, tub or squeeze	1 tsp
Mayonnaise	
reduced-fat	1 Tbsp
regular	1 tsp
Oil: corn, cottonseed, flaxseed, grape seed, safflower, soybean, sunflower	1 tsp
Salad dressing	
reduced-fat	2 Tbsp
regular	1 Tbsp

Saturated Fats	**Serving Size**
Bacon, cooked, regular or turkey	1 slice
Butter, stick	1 tsp
Cream, half and half	2 Tbsp
Cream cheese	
reduced-fat	1 ½ Tbsp (¾ oz)
regular	1 Tbsp (½ oz)
Sour cream	
reduced-fat or light	3 Tbsp
regular	2 Tbsp

Free Foods

Each serving from this list has **5 grams or less of carbohydrate** and less than 20 calories per serving. Eat up to 3 servings per day of the free foods with a serving size noted without counting any carbohydrate. Choices listed without a serving size noted can be eaten whenever you like. For better blood glucose control, spread your servings of these foods throughout the day.

Low Carbohydrate Foods	**Serving Size**
Cabbage, raw	½ cup
Gelatin, sugar-free or unflavored	
Gum	
Jam or jelly, light or no sugar added	2 tsp
Salad greens	
Sugar substitutes (low calorie sweeteners)	

Modified Fat Foods with Carbohydrate	**Serving Size**
Cream cheese, fat-free	1 Tbsp (½ oz)
Creamers	
nondairy, liquid	1 Tbsp
nondairy, powdered	2 tsp
Salad dressing	
fat-free or low-fat	1 Tbsp
fat-free Italian	2 Tbsp

Condiments	**Serving Size**
Barbecue sauce	2 tsp
Catsup (ketchup)	1 Tbsp
Mustard	
! Pickles, dill	1 ½ medium
Salsa	¼ cup
Taco sauce	1 Tbsp
Vinegar	

Drinks/Mixes

! Bouillon, broth, consommé
Carbonated or mineral water, club soda
Coffee or tea
Diet soft drinks or sugar-free drink mixes

Seasonings

Flavoring extracts
Garlic
Herbs, fresh or dried
Nonstick cooking spray
Spices
Worcestershire sauce

Combination Foods

Combination foods contain foods from more than one food list, but with the help of a Registered Dietitian (RD) you can fit these foods into your meal plan.

Entrees	**Serving Size**
! Casserole type (tuna noodle, lasagna, macaroni and cheese) *(Count as 2 carbohydrates + 2 medium-fat meats)*	1 cup (8 oz)

Frozen Meals/Entrees	**Serving Size**
!☺Burrito (beef and bean) *(Count as 3 carbohydrates + 1 lean meat + 2 fats)*	1 (5 oz)
!Enchilada *(Count as 3 carbohydrates)*	1 (11 oz)
! Pizza, cheese/vegetarian, thin crust *(Count as 2 carbohydrates + 2 medium-fat meats)*	¼ of a 12 inch (4 ½-5 oz)
!Taco *(Count as 2 carbohydrates)*	1 (5-6 oz)

Soups	**Serving Size**
! Bean, lentil or split pea *(Count as 1 carbohydrate + 1 lean meat)*	1 cup
! Tomato (made with water) *(Count as 1 carbohydrate)*	1 cup

These Food Lists are not intended to be all inclusive. Consult with your RD about any foods that you eat which are not listed.

Sample Meal Plan

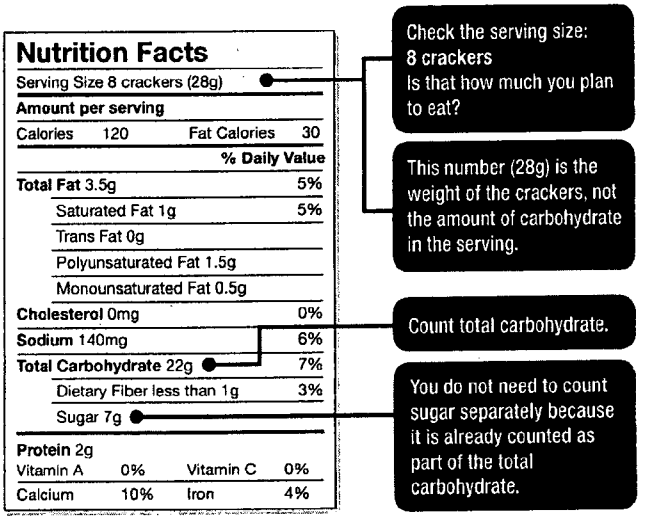
The table below shows sample meal plans, by number of servings, for different calorie levels. Ask your RD, diabetes educator, or healthcare provider which plan works best for you. Each plan provides about half of its calories from carbohydrate and less than 25% of calories from fat, based on choosing fat-free milk and low-fat meats (Lean Meat Group) and cheeses.

Calories per day*					
	1200	1600	1800	2000	2200
Carbohydrates					
Starches	5	7	8	9	10
Fruits	3	3	3	4	4
Milk	2	3	3	3	3
Sweets, Desserts, & Other Carbohydrate					
Nonstarchy Vegetables	3	4	5	6	6
Meat & Meat Substitutes	4 oz	6 oz	6 oz	7 oz	8 oz
Fats	3	5	6	6	7

*The numbers included in the chart are individual servings from each food list.

Alcohol – In general, 1 alcohol equivalent has about 100 calories. One alcohol equivalent is 12 ounces beer or 1 ½ ounces distilled spirits or 5 ounces wine. If you choose to drink alcohol, limit it to 1 drink or less per day if you are a woman and 2 drinks or less per day if you are a man.

Carbohydrate Counting



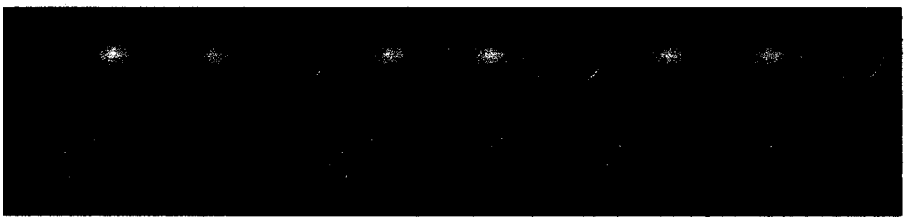
Carbohydrate (starch and sugar) is the main nutrient in food that raises blood glucose. When you plan meals based on carbohydrate counting, count only the foods that contain carbohydrate. Use either the portion sizes shown in the Food Lists, or calculate the carbohydrate grams or choices using the bolded carbohydrate numbers at the top of each food list. If you are using a packaged food with a Nutrition Facts label, count the number of "Total Carbohydrate" grams based on the serving size listed on the label.

How much carbohydrate do you need?
Your RD can help decide how much carbohydrate you need. The amount depends on your age, weight, activity, and diabetes medications if needed.

It's important to know that...
1 carbohydrate choice = 15 grams carbohydrate

Women often need about 45-60 grams carbohydrate (3-4 choices) at each of three meals and 15 grams carbohydrate (1 choice) for snacks as needed.

Men often need 60-75 grams carbohydrate (4-5 choices) at each of three meals and 15-30 grams carbohydrate (1-2 choices) for snacks as needed.



TO CALCULATE CARBOHYDRATE CHOICES:
Divide the number of grams of total carbohydrate by 15 (because 1 carbohydrate choice = 15 grams of carbohydrate).
Total carbohydrate = 22g
22 divided by 15 = 1.5 (round to 2)
So, 8 crackers = 2 carbohydrate choices

THE HEALTHY HEART

REDUCED SATURATED FAT AND CHOLESTEROL

Saturated fat and cholesterol are the two biggest threats to your heart. Do your heart a favor, and choose low fat, low cholesterol foods whenever possible.

FOODS TO CHOOSE	FOODS TO LOSE
Canola oil, olive oil, olives, avocado, nuts	Coconut oil, palm oil, coconut, butter
Non-fat or 1% milk, non-fat or low fat yogurt	Cream, whole milk, powdered creamers
Fresh fruits and vegetables, plain frozen vegetables	Vegetables fried in deep fat
Whole grain bread, cereal, pasta, pretzels	Donuts, muffins, pastries
Fish, White meat chicken and turkey, dried beans, tofu, lean cuts of meat	Hot dogs, bacon, beef, sausage, liver, bologna, salami

LOW FAT COOKING TIPS

- ♥ Broil, roast, bake, steam or microwave fish, chicken, turkey and red meat.
- ♥ Take the skin off chicken and cut the extra fat off meat before you cook it.
- ♥ Brown meat under the broiler.
- ♥ Use wine or broth instead of fat.
- ♥ Use nonstick pans or cooking sprays

MORE HEART HEALTHY EATING

Heart healthy eating starts with making the right choices for meals and snacks. If you prepare the meals in your household, your healthy choices will be good for the whole family.

Choose Fats Wisely

Pick unsaturated fats. This type of fat is good for you in small amounts. It is found in nuts, seeds, fish, avocados, and vegetable oils (not hydrogenated).

Limit saturated fats. It raises LDL (bad) cholesterol. This fat is mostly found in animal foods (such as beef, chicken or dairy). Eat as little of this fat as you can. Try to use unsaturated fat instead. For instance, cook with vegetable oil instead of butter.

Avoid trans fats. This is found in snack foods, shortening, fresh fries, and stick margarine. Even if it is not listed on the back label, look for it in the ingredients in the form of hydrogenated or partially hydrogenated oils.

What About Cholesterol?

The level of cholesterol in your blood shows if you are at risk for heart disease. Your body makes some cholesterol. Cholesterol is

also absorbed into your blood from the foods you eat. Egg yolks, organ meat, and fatty animal foods are some foods that are high in cholesterol. Most high cholesterol foods are high in saturated fat. So eating less saturated fat will help lower your cholesterol.

Find Hidden Sodium

Your body does need some sodium (salt), but too much can raise blood pressure. Be aware that sodium is "hidden" in many foods. These include canned soup and vegetables, packages pasta and rice dishes, condiments such as ketchup, and snack foods such as chips. Sodium is also hidden in most restaurant and fast foods.

Read Food Labels

Reading food labels is the best way to keep track of what's in the food you eat. Labels can help you see how much fat and sodium is in packaged food. With a little practice, getting the information you need from labels is easy. Keep serving size in mind. If you eat twice as much as one serving size, you must double all the other numbers on the label.

PRODUCE POWER

Apples contain vitamins A and C. Studies show that apples also have cancer – and virus – fighting agents and can work as anti-inflammatories. The boron in apples boosts blood level of estrogen and the other compounds to prevent calcium loss in bones.

Artichokes are full of fiber, which is known to combat Type 2 diabetes – a fourth leading cause of death by disease in the United States.

Bananas are rich in potassium, a mineral that regulates heart beat and blood pressure and can protect the elderly from strokes. Bananas are also commonly recommended to stabilize irritable intestines, thus alleviating both constipation and diarrhea.

Beets are a great source of the cancer-fight antioxidant betacyanin, which gives them their vibrant color. Fresh beets are full of folic acid and vitamin B, which may protect against heart disease and colon cancer.

Blueberries contain tannic acid, which many scientists believe neutralizes free radicals and acts as a potent virus killer. Others claim it helps cure diarrhea and fights off bladder and urinary track

infections. European ski lodges often serve blueberry soup as a cold remedy.

Broccoli is one of the first vegetables found to have anti cancer properties and is still considered among the most potent. The sulforaphane in broccoli is said to stimulate the body to produce an enzyme that kills potential carcinogens. Other vegetables in the cruciferous family, such as cabbage, cauliflower and brussel sprouts, also fight disease.

Eggplant contains two compounds used to stop convulsions: scopletin and scoparone. It is being investigated for its potential use in the treatment of epilepsy. Studies show this vegetable also binds up cholesterol in the intestines so that it isn't absorbed into the blood stream where it can clog arteries.

Grapes possess high levels of caffeic acid, which has been found to prevent cancer in animals, and flavonoids, which may prevent blood clots. Several dietary surveys have found that snacking on grapes lowers the incidence of gum disease.

Oranges, lemons and limes have vitamin C, bioflavonoids and an abundance of limonene. These help the body fight cancers of the lung, cervix, stomach, and esophagus by reducing cholesterol and boosting enzymes thought to break down carcinogens and stimulates cancer killing immune cells.

Pineapples are high in the mineral manganese, which research suggests helps build strong bones and prevents osteoporosis. A single cup of pineapple juice provided 50% of the recommended daily amount of vitamin C; fresh pineapple contains brome lain, an enzyme that helps digestion by breaking down protein.

GROCERY SHOPPING

Do you want to control your cholesterol? Read food labels and buy foods low in saturated fat and low in cholesterol. Here is a shopping list:

- Whole wheat, rye or pumpernickel bread
- Soft tortillas (corn, or whole wheat)
- Hot and cold cereals, except granola or muesli
- Fruits (any fresh, canned, dried or frozen without added sugar)
- Vegetables (any fresh, frozen or low-salt canned without cream or cheese sauce)
- Fresh or frozen juices, without added sugar
- Fat- free or 1% milk
- Cheese (with 3 grams of fat or less per serving)
- Low-fat or non-fat yogurt
- Lean cuts of meat (eye of round beef, top round, sirloin, pork tenderloin)
- Lean or extra lean ground beef
- Chicken or turkey (remove skin)
- White meat fish
- Tuna (light meat canned in water)
- Peanut butter (reduced fat)
- Eggs, egg whites, egg substitutes
- Low-fat cookies or angel food cake
- Low fat frozen yogurt, sherbet
- Popcorn, pretzels, baked tortilla chips
- Vegetable oil (canola, olive, corn, peanut, sunflower)
- Nonstick cooking spray
- Sparkling water, tea, lemonade

10 STEPS TO SMARTER FOOD SHOPPING

You came, you shopped. But then you got home form the supermarket and started unloading fatty snack items and deli meats. What went wrong? You fell back into the habit of shopping like an average American rather than a person with a dietary purpose. In an enticing palace of eating designed to lead you astray, here's how to stay on track.

1. **Make a list** - Before you shop, write down what you need – to reduce the chances of buying what you don't.

2. **Limit your trips** – Make your shopping list long so you have to make only one or two trips to the store per week. Besides being more efficient, this provides less opportunity to make less impulse purchases.

3. **Avoid shopping on an empty stomach** – When you're hungry, you're more likely to grab high-fat snacks and desserts.

4. **Follow the walls** – Limit browsing to the perimeter of the store, where you'll find the freshest, most healthful foods: raw produce, low-fat dairy products, fresh lean meats and fish. Venture into the interior isles only when you're after specific foods such as pasta and dried beans, to avoid picking up extra items not included in your diet plan.

5. **Pay attention to portions** – Those cookies look great – and hey, eating them only costs you 75 calories. But check the serving size: 1 cookie. Eating "them", say three cookies – brings your calorie count up to 225.

6. **Ignore pictures** – Golden sunshine glows on heaps of freshly harvested grains – and image of good health which signifies nothing. Look at the side of the box instead for the facts, and choose foods that are high in fiber and low in fat and calories.

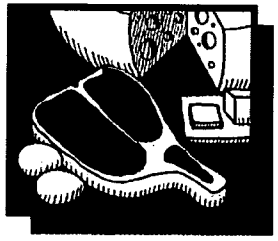
7. **Grade your grains** – Want high fiber bread? Look for the words "whole grain" or "stone ground" on the label. Breads labeled simply "wheat" – even if the are brown in color – may not contain whole grains. True whole grain bread contains at least 2 grams of fiber.

8. **Watch the language** – Beware of foods labels "no sugar added" – the wording is carefully chosen, because the product may be loaded with natural sugar. You'll find the real story on the label under "Sugars".

9. **Add some spice to your life** – Instead of creamy condiments, load up on such spices as basil, chives, cinnamon, cumin, curry, garlic, horseradish, nutmeg, oregano, paprika, parsley and Tabasco sauce. They're very low in carbohydrates, fat, protein and calories.

10. **Keep your eye on the cashier** – You're waiting in line, nothing to do – a captive audience. It's no accident that supermarkets pile their impulse items next to the registers. Keep a couple of items from your basket in your hands. It'll stop you from reaching for the candy bars.

DIET TIPS FOR LOWER CHOLESTEROL



FOR MEAT AND PROTEIN FOODS,

CHOOSE:

- ❑ Fish and shellfish
- ❑ Chicken and turkey without skin
- ❑ Ground turkey—only 15% fat
- ❑ Lean, well-trimmed beef, veal, lamb, and pork, with very little marbling
- ❑ Small servings of meat, seafood, and poultry—7 ounces or less per day
- ❑ Meatless protein occasionally—dried beans, lentils, split peas, peanut butter, tofu—instead of meat protein
- ❑ Only 2 egg yolks per week (including those used in baked products and mixed dishes)

LIMIT:

- ❑ Large servings of shrimp
- ❑ Fried chicken, duck
- ❑ Fatty ground meat
- ❑ Liver and organ meats
- ❑ Prime, heavily marbled cuts of meat
- ❑ Bacon, sausage, high-fat deli meats

FOR MILK, CHEESE, AND DAIRY PRODUCTS,

CHOOSE:

- ❑ Skim or 1% low-fat milk only
- ❑ Low-fat milk, evaporated skim milk, or nonfat dry milk powder in place of cream
- ❑ Frozen yogurt, ice milk, sherbet, or sorbet instead of ice cream
- ❑ Low-fat or nonfat yogurt
- ❑ Low-fat cheeses—1% cottage cheese, skim-milk ricotta, skim-milk mozzarella, skim-milk American cheese products

LIMIT:

- ❑ Any milk containing more than 1% fat (whole, 2%)
- ❑ Cream, half & half, nondairy creamer
- ❑ Ice cream, whipped cream, nondairy whipped toppings
- ❑ Whole-milk yogurt, sour cream
- ❑ Whole-milk cheeses—Cheddar, American, Swiss, Muenster, cream cheese, Brie

FOR FRUITS AND VEGETABLES,

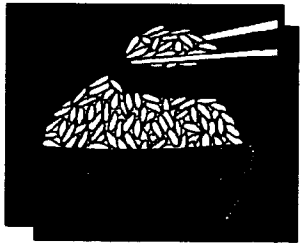
CHOOSE:

Several servings of these low-fat, high-nutrition foods daily:

- ❑ Raw, steamed, boiled, baked, or stir-fried vegetables
- ❑ Vegetables seasoned with herbs, lemon juice, or a small amount of margarine

LIMIT:

- ❑ Coconut—the only fruit high in saturated fat
- ❑ Deep-fat-fried vegetables
- ❑ Cream sauce, cheese sauce, or butter on vegetables



FOR BREADS AND CEREALS,

CHOOSE:

- ❑ Plain breads, English muffins, bagels
- ❑ Plain pasta, rice
- ❑ Hot or cold cereal with no added fat
- ❑ Low-fat snack foods—pretzels, air-popped popcorn, rice cakes, Scandinavian flatbread crackers, melba toast
- ❑ Low-fat baked goods—angel food cake, fruit cookies, graham crackers, gingersnaps, fortune cookies

LIMIT:

- ❑ High-fat baked goods—donuts, Danish pastry, croissants
- ❑ Fried rice, crispy chow mein noodles
- ❑ Granolas with coconut or coconut oil added
- ❑ High-fat chips, cheese crackers, butter crackers
- ❑ High-fat cakes, cookies, pies

FOR HIGH-FAT FOODS,

CHOOSE:

- ❑ Margarine or diet margarine made with liquid safflower, corn, or sunflower oil
- ❑ Cooking oils high in monounsaturated fatty acids, such as olive and peanut oils, or oils high in polyunsaturates, such as safflower, sunflower, corn, and soybean oils
- ❑ Salad dressings and diet dressings made without saturated oils
- ❑ Nut snacks in moderation. (Although the fat in these foods is primarily unsaturated, they are high in total fat and calories.)

LIMIT:

- ❑ Butter or margarines made with partially hydrogenated oil
- ❑ Lard, meat fat, hydrogenated or partially hydrogenated solid vegetable shortening; products made with coconut or palm oil
- ❑ Salad dressings made with sour cream or cheese
- ❑ Chocolate—high in saturated fat

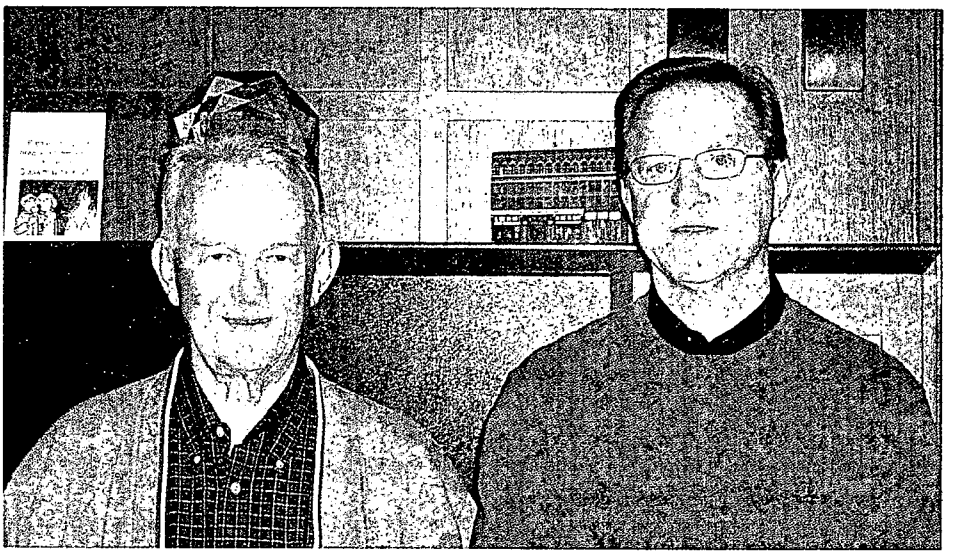
Spring 2007

THE BEAT GOES ON



Message from the Executive Director

Loraine C. Shea
Executive Director,
Heart Center of
Greater Waterbury

February has traditionally been the month associated with hearts, whether it is the colorful cut out hearts on a greeting card or the quick beating heart of one in love. And every year since 1963, February has been declared American Heart Month. During February all of us are urged to increase our awareness of cardiovascular disease and ways to prevent it. In this edition of "The Beat Goes On" we feature information on diagnostic procedures, tips for coping after a heart attack and the personal stories of two of your neighbors. These former patients at Saint Mary's Hospital and Waterbury Hospital are just two of the hundreds of lives in the Greater Waterbury Community that the Heart Center has improved with its excellent cardiac care and ongoing heart health education. Enjoy the issue!

To learn more about Heart Health, log on to our website www.hcogw.org.

Michael McCormack of Woodbury (left) and Jim Zukauskas of Waterbury. Both men had successful heart surgery last October—Michael at Waterbury Hospital, and Jim at Saint Mary's Hospital.

Saving Lives in Waterbury

When people think of receiving top notch health care, they might think they have to travel to a distant city. Now, thanks to the efforts of Saint Mary's Hospital and Waterbury Hospital, advanced cardiac care is available close to home. The two local hospitals have teamed up with the University of Connecticut Health Center to create the Heart Center of Greater Waterbury. Since the program began in July of 2005, literally hundreds of people have received a standard of care that had never been available in this area before.

Michael McCormack of Woodbury is but one example of a very satisfied patient. His internist, Dr. Michael Trager, discovered an irregular heartbeat while performing a routine EKG. McCormack, who had a family history of heart disease, was shocked to find that the left side of his heart was completely blocked. Because of this dangerous condition, cardiologist Dr. Michael Malinics prescribed immediate surgery to correct the condition. "On October 10 I played golf," he said. "On October 11 I was in the hospital having a catheterization." Following successful bypass surgery at Waterbury Hospital, McCormack is now in the midst of a cardiac rehab program, an integral component of the Heart Center program.

Jim Zukauskas of Waterbury has a similar story. Zukauskas, a postal

THE ROAD BACK: LIFE AFTER A HEART ATTACK

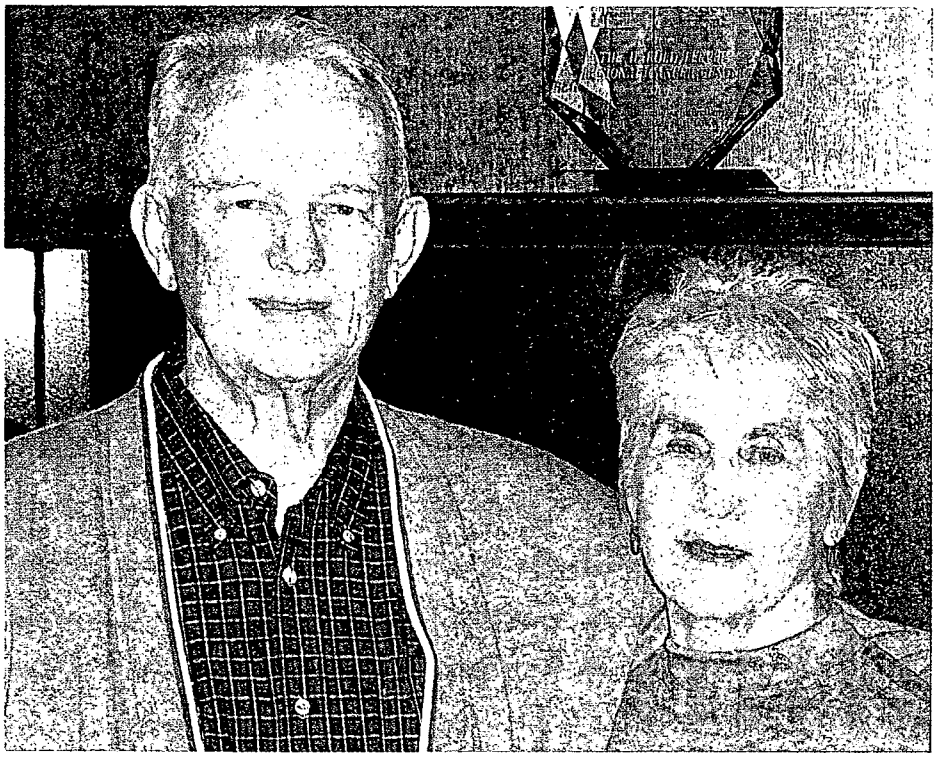
Every year, nearly 1 million Americans survive a heart attack. If you're one of them, you may be facing not only physical but also emotional challenges. You may feel fearful, angry, or depressed at times. You may wonder how you'll ever get back to "normal" life. In fact, the real road to recovery doesn't lead back; it leads forward, to a new and healthier life.

How You Can Get There

Your recovery plan may include both medication and lifestyle changes.

Keep yourself on track with these tips:

- Remember that the changes you're making will benefit you for the rest of your life.
- Share your feelings with people you trust. Your doctor can recommend a counselor or support group.
- Always take any medication as prescribed.
- Tell your doctor about any physical symptoms or problems immediately.



How Others Can Help You

Here's what friends and family can do to be a positive part of your recovery:

- Encourage you in your new habits by joining you in exercising, for example, or sharing heart-healthy recipes.
- Avoid smoking around you.
- Visit with a counselor or support group.
- Learn heart attack warning signs—chest pain; shoulder, neck, or arm pain; dizziness, sweating, or nausea; or shortness of breath. ●

If your community group is interested in Heart Health Education, call 203-575-5573.

Saving Lives in Waterbury *continued from pg.1*

Michael McCormack and his wife Evelyn McCormack.

worker, had open heart surgery in October. Because his procedure was elective, he was able to choose his surgeon to do his procedure. And that's when he met Dr. Paul Preissler. "I have nothing but praise for this gentleman," said Zukauskas. "He is smart, confident, and compassionate. After talking with him, I knew he was the surgeon for my needs. He literally saved my life."

Zukauskas was a patient at Saint Mary's Hospital, where he was cared for in the Cardiovascular Unit, or CVU. Both Saint Mary's Hospital and Waterbury Hospital utilize a model of care called "one stop post-op," which ensures that a patient receives all of his or her care in a single unit, instead of moving from place to place during the hospitalization. "No other hospital in Connecticut utilizes this model for cardiac care," according to Loraine Shea, Executive Director of the Heart Center. "The theory is that by keeping patients with the same medical team, any issues or complications will be picked up quickly and the patient will ultimately have a shorter stay."

Jim Zukauskas.

"The cardiovascular unit at Saint Mary's was great," according to Zukauskas. "Everyone had a private room. The people were right there giving us constant care. They were very professional, sincere, compassionate and genuinely concerned about my well being and progress. I told my girlfriend that I believed my nurse, a gentleman named Julius, was wonderful." Zukauskas was pleased that he didn't need to leave the area to receive this level of care. "I think it's fabulous," he said, "I'm not sure the public is aware of these qualified physicians and the programs available at these two hospitals."

Mr. McCormack also gave Waterbury Hospital high grades. "Now that Waterbury Hospital has the heart program, it's excellent," says McCormack. "We live in Woodbury so it was really convenient for us—my wife could come right over. It's very comforting to know that we have such a great team of experts within twenty minutes of our house. It's awesome."

If you're concerned about your heart health, be sure to talk with your primary care physician or your cardiologist about the cardiac services available at the Heart Center of Greater Waterbury. ●

If you are recovering from a heart related procedure, you may be interested in the Heart Center's Support Group. See the Upcoming Events on page 2.

Start Your Day the Heart-Healthy Way—with a Hug

You're eating a low-fat diet. You exercise regularly. You don't smoke. So, what's missing from this heart-healthy regimen? Hugs, say researchers.

Some recent studies of couples show that a caring hug can help lower blood pressure and heart rate, especially during stressful moments.

The researchers suggest that a hug each morning might help protect you and your partner's hearts in ways that no pill can.

Picturing Your Heart

To obtain diagnostic X-rays of your heart or arteries—called a coronary angiogram—your doctor may recommend a common procedure called cardiac catheterization. From start to finish, it takes one to several hours. A long, thin tube called a catheter will snake through the artery in your neck, groin, or arm to your heart, guided by X-ray photography. Here's what to expect:

- You'll probably be told not to eat or drink anything for six to eight hours beforehand.
- A mild sedative will be given to help you relax, but you'll need to stay awake to follow instructions; you may even be able to watch the procedure on a monitor the doctor uses to see the motion of your blood.
- A small area of your neck, groin, or arm will be shaved, cleaned, and anesthetized, and a tiny incision—the size of a pencil point—is made to insert the catheter.
- A dye injected through the catheter will show your heart and coronary arteries. These X-ray pictures will indicate how your heart is working and, if an artery is blocked or narrowed, the pictures will pinpoint the exact location. ●

Summer 2007

THE BEAT GOES ON

Message from the Executive Director

Lorainc C. Shea
Executive Director,
Heart Center of
Greater Waterbury

As you read this issue of "The Beat Goes On," the Heart Center of Greater Waterbury approaches its second anniversary. For nearly two years your community hospitals have been providing advanced cardiac services and have saved more than 1,500 hearts. In addition to the quality cardiac care services provided at Saint Mary's Hospital and Waterbury Hospital, this newsletter serves as a reminder to you that keeping your heart healthy is important to your overall well-being. In this issue you will learn the warning signs of a heart attack, understand how smoking impacts your cardiac health, and increase your knowledge about cholesterol lowering drugs.

Keeping you informed and keeping you healthy is our ultimate goal. Enjoy the issue and have a heart-healthy summer!

Freedom From Smoking

A Real Team Effort

In April, the Heart Center of Greater Waterbury (HCGW), through grant dollars from the American Heart Association (AHA), teamed up with the American Lung Association (ALA) to bring the second of three separate eight-week Freedom From Smoking Clinics to Waterbury.

"Smoking is one of the most common risk factors for heart disease," says Sandra Micalizzi, APRN, Community Outreach Nurse for HCGW. "The nicotine present in cigarette smoke causes decreased oxygen to the heart, increased blood pressure and heart rate, increased blood clotting, and damage to cells that line coronary arteries. All of these factors put undue strain on the work of your heart. Because Waterbury has not had a smoking-cessation program for some time now, we felt it was important to provide the resources that people needed to quit! We've been very fortunate to work with the American Lung Association on this program." Group facilitators from the ALA focus on the benefits of quitting and on techniques for managing stress, increasing motivation, overcoming cravings and for coping once the participant has quit. Since January, 60 community members have taken the first step toward improving overall health and well-being by taking advantage of this very comprehensive and proven program.●

DON'T STRESS OVER YOUR STRESS TEST

There's no need to worry about an upcoming stress test. They are generally safe for most people. They also are one of the best ways to learn about your current heart health.

Putting Your Heart to Work

The most common stress test is an exercise electrocardiography (ECG), which measures your heart's electrical activity. This shows how well your heart functions while it's pumping hard. ECG results can help your doctor diagnose heart problems, develop the best treatment plan for you, and determine if current treatments are effective.

During an ECG, you walk on a treadmill with patches that contain electrodes attached to your skin. The test is painless, but some patients may experience symptoms, such as chest pain. Serious problems are rare. You will be monitored during and after the test to make sure you're doing OK.

If you are unable to exercise because of arthritis or other health problems, you can still have an ECG—without moving. In this case, you will be given a specific medicine to increase your heart rate.

Several other types of stress tests also are available. For example, women may benefit more from an exercise echocardiography, which involves taking an ultrasound of the heart during exercise.

Getting Ready for Your Test

There's no way to prep your heart for a stress test. But you can take some steps to help ensure that the test goes smoothly and safely:

- ♥ Don't eat or drink anything with caffeine, including coffee or chocolate, for several hours before the test.
- ♥ Ask your doctor if any of your medicines could present a problem. Some, including digoxin and beta-blockers, may affect test results.
- ♥ Dress in comfortable clothes and shoes.●

If your physician recommends a stress test, they can schedule it for you at the Outpatient Cardiology Departments at either of the two community hospitals: Saint Mary's Hospital (203-709-6361) or Waterbury Hospital (203-573-7264).

WHAT ABOUT CHOLESTEROL FIGHTING DRUGS?

Henry Borkowski, MD, Medical Director,
Heart Center of Greater Waterbury,
answers your questions on cholesterol lowering drugs

Q: What exactly is cholesterol?

Dr. Borkowski: Cholesterol is a substance both made by the body and consumed in food products that come from animals. Primarily, it travels in the blood as two compounds: low-density lipoproteins (LDL) and high-density lipoproteins (HDL).

In practice, HDL is often called the "good" cholesterol and LDL is called the "bad" cholesterol. The reason for this is that HDLs help transport cholesterol in the body to the liver, where the body then prepares to excrete it. LDLs, on the other hand, actually transport cholesterol from the liver to cells in the body. Once the body's cells have all of the cholesterol they need, the extra cholesterol can build up along blood vessel walls as plaque. People with high total cholesterol to HDL cholesterol ratios are at increased risk for heart disease because, in general, they are transporting more cholesterol to cells than they need.

Q: Are diabetics more at risk for high cholesterol?

Dr. Borkowski: For people who develop diabetes as adults, damage to blood vessels can be a major problem. Substances from fatty and sugar-based foods can build up inside vessels, restricting blood flow. Up to 80 percent of people with type 2 diabetes develop blocked arteries, which can cause a heart attack or stroke. Therefore, controlling cholesterol for diabetics is very important.

Q: What is the best way to keep cholesterol at a manageable level?

Dr. Borkowski: Decreasing cholesterol in an effort to reduce fatty buildup is important to prevent heart disease in all of us. Although diet and exercise are important in controlling cholesterol, more than 90 percent of patients cannot control their cholesterol with diet alone. Therefore, cholesterol lowering drugs also may be prescribed. The safest, most effective choices are the family of drugs called statins. Studies show that cholesterol lowering drugs reduce blood vessel problems in people with diabetes by about 25 percent.

Q: Are there side effects of statins?

Dr. Borkowski: Serious side effects from statins are extremely rare. However, you may need regular blood tests to monitor the effects of the drug if you have liver or muscle disease or take certain other drugs. Ask your doctor whether a statin is right for you.

Q: Who should take statins?

Dr. Borkowski: The most important message here is to consult with your physician for guidance. Whether you should take statins is determined by evaluating your age, gender, and good and bad cholesterol levels, as well as your risk factors for cardiovascular disease, including smoking, high blood pressure, and family history of heart disease. In addition, patients who already have heart disease, symptomatic carotid artery disease, peripheral arterial disease, or abdominal aortic aneurysms may require statin therapy.●

Chest Pain: When Is It a Heart Attack?

Many people know that chest pain could signal a heart attack. But chest pain can also indicate other health problems. When should you worry?

Prolonged chest pain is considered the telltale symptom of a heart attack. But it's not always simple to tell when a heart attack occurs.

Heart Attacks Vary

Some heart attack sufferers report severe chest pain, while others only feel some chest discomfort. And about one-third of heart attack sufferers do not feel any chest pain at all.

Other symptoms besides chest pain are also common during heart attacks. These include:

- ♥ Left arm pain
- ♥ Pain that radiates to the neck or jaw
- ♥ Shortness of breath
- ♥ Nausea
- ♥ Dizziness
- ♥ Sweating

Certain people are more likely than others to have an atypical heart attack—or one that is characterized by symptoms other than chest pain. They include women, younger and older adults, and people who suffer from diabetes or high blood pressure.

Don't Wait to Act

It's vital to get prompt treatment for a heart attack. Whenever you or a loved one experience heart attack symptoms, it is important to get to medical care as soon as possible. These services are available close to home at both Saint Mary's Hospital and Waterbury Hospital; quality care where and when you need it.

If you know of a community group interested in a Heart Health educational program, contact the Heart Center at 203-575-1992.●

Even Light Smoking Can Jumpstart Heart Disease

Puffing just one or two cigarettes a day may be enough to harm your heart and blood vessels. One study involving 23 men found that smoking a pack or less a week seems to trigger early signs of heart disease. Ultrasound and other tests confirmed that light smoking damaged the lining of the blood vessels about as much as smoking a pack a day or more.

Fall 2007

THE BEAT GOES ON

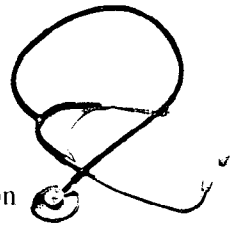
Message from the Executive Director

Loraine C. Shea
Executive Director,
Heart Center of
Greater Waterbury

The Heart Center of Greater Waterbury recently completed its second year of providing advanced cardiac services at both Saint Mary's Hospital and Waterbury Hospital. The Waterbury community can now receive routine and emergency cardiac services close to home. In addition to providing life saving services to over 1800 hearts, HCGW is committed to educating the community about heart related matters. In this issue we stress the importance of recognizing heart related symptoms early and seeking treatment quickly when needed.

In today's busy world, one of our top priorities should be our own health. Recognizing that you or a loved one may be having a heart related event and getting to your physician or the emergency room fast is important for appropriate treatment and overall outcomes. Stay informed and act fast. It may save another heart!

Minutes Matter...
During a Heart Attack



If you think you are having a heart attack, don't let any time pass before seeking assistance. To be most effective, treatments must be given within one hour after symptoms begin. That's why experts advise calling 911 as soon as symptoms are experienced. Emergency medical personnel can start treating you immediately, even before you get to the hospital.

Save Your Heart

The longer the blood supply to the heart is disrupted, the more damaged the heart becomes. A damaged heart can make it difficult to engage in everyday activities. According to a recent study in the *American Journal of Cardiology,* heart attack patients had a 16 percent greater risk of impaired heart function for every hour they delayed getting to the hospital.

Not All Heart Attacks Are the Same

Heart attacks vary widely from patient to patient. Some come on suddenly, accompanied by severe pain. Others are easy to confuse with less serious ailments.

The most common symptom in women and men is chest pain or discomfort. This discomfort is sometimes described as an uncomfortable pressure, fullness, squeezing, or pain in the center of the chest that lasts more than a few minutes. Sometimes the pain goes away and then comes back.

One study found that subjects expected chest discomfort to be severe. In reality, the intensity varies. Joseph Iannantuoni

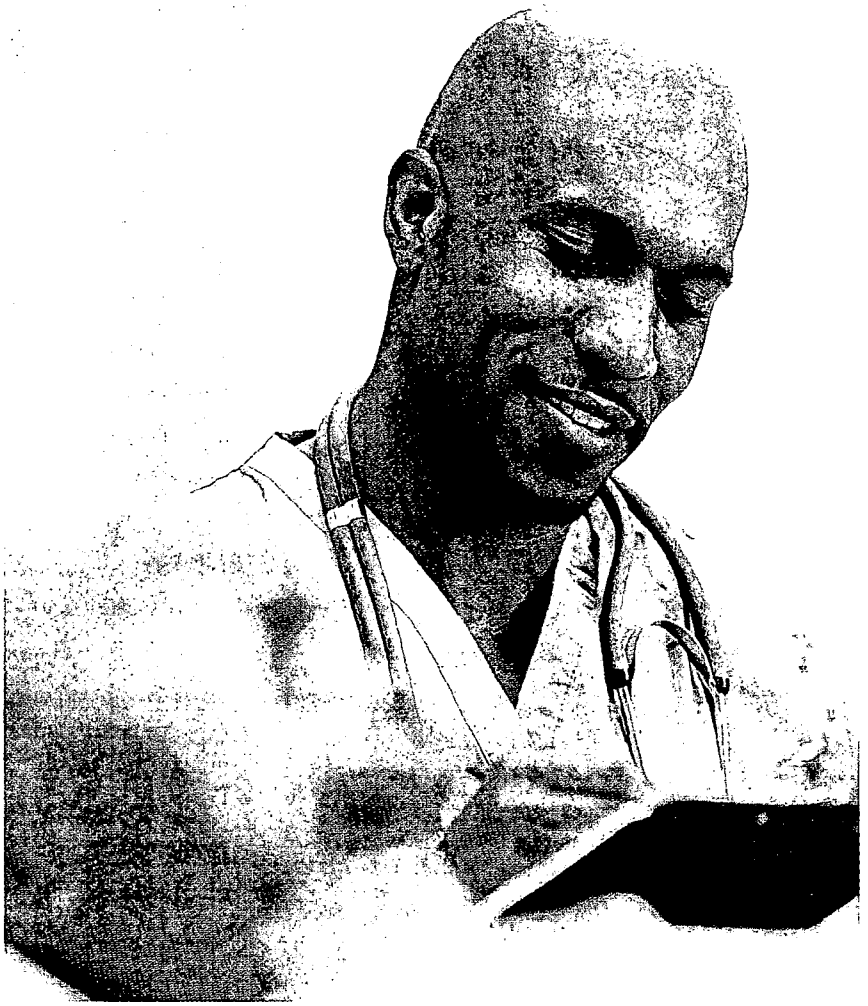
AEDs: PORTABLE DEVICES THAT CAN SAVE LIVES WHEN MINUTES COUNT

Most people probably have seen TV images of patients getting "shocked" with paddles in an emergency room because their heart stops beating. But what happens when someone's heart stops at the mall? Nowadays, this person could have a higher chance of survival, thanks to automated external defibrillators (AEDs).

These portable devices are compact versions of equipment found in hospitals. AEDs deliver an electrical shock to help "restart" the heart. And they're so simple and safe that even people without medical training can use them.

Ideally, victims should receive the shock within five minutes after their heart stops, or what's called cardiac arrest. That's why some health organizations recommend that AEDs be available in public places, such as airports and sports arenas. These minutes can make a big difference. Studies have shown that an AED can more than double the chance of surviving cardiac arrest.



Today, many flight attendants, police officers, firefighters, and others take a short class on how to use AEDs. But people don't necessarily need to take a class to use one. Recent advances have made these devices safe and easy enough for almost anyone to use. Research has shown that AEDs are simple enough for even sixth-graders to operate. Several studies have shown that AEDs can tell with 100 percent accuracy whether a victim really needs a shock.

The National Institutes of Health and the American Heart Association are currently funding a large study of AEDs. Some experts think they may eventually become nearly as common in public places as fire extinguishers.●

of Waterbury knows this firsthand. When he experienced some chest pressure in March 2007 he was encouraged by his wife to get to the Emergency Department. Because Mr. Iannantuoni had suffered a heart attack twenty-five years before with "crushing pain," this mild pressure did not concern him. Recognizing the symptoms and seeking treatment immediately assured that he was back to his normal routine within days.

Symptoms Differ for Women

In addition to chest discomfort, other symptoms are common. But these may differ between women and men. "Women need to understand that their symptoms may present very differently than their male counterparts," confirms Robin Cracco, RN, MSN, CEN, Director of Nursing for the Emergency Department at Saint Mary's Hospital. "Women are significantly more likely than men to complain of upper abdominal pain, shortness of breath, nausea, and fatigue which are not commonly thought of as symptoms of a heart attack."

Other symptoms of a heart attack include pain that spreads to the shoulders, neck, or arms, lightheadedness, dizziness, fainting, and sweating.

Recognize the Signs

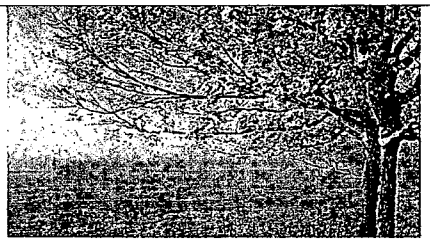
The first step to getting fast treatment for a heart attack is to know the symptoms. For some, they are unsure if what they are experiencing is heart attack symptoms or heartburn. "Individuals may choose not to seek treatment if they believe their symptoms indicate heartburn," says Gail Snow, RN, Nursing Director of the Emergency Department at Waterbury Hospital. "It's important for our community to know that cardiac symptoms are treated as a cardiac problem until a definite diagnosis is determined. No one should be embarrassed about seeking treatment in the Emergency Room if they are unsure of what their symptoms mean. It is much better to be safe than sorry."

Other clues can help you distinguish heartburn from a heart attack. Heartburn often occurs after meals, particularly when lying down. Coughing and a bitter or sour taste in the back of the throat also may be present.

Typically, however, that's the extent of heartburn symptoms. Heart attacks, on the other hand, often involve a number of different symptoms in addition to chest pain.

Don't Delay Treatment

If you are having any type of chest related pain the important thing is to have it checked. Unfortunately, many Americans delay seeking treatment for a heart attack—by six hours or more. Women are especially prone to delay. Minutes do matter—don't wait to seek help. Call 911.●



To learn more about early symptom recognition, plan on attending one our community based education sessions. See Upcoming Events on Page 2.

Fall into Fitness

with These Exercise Tips

Autumn usually brings a welcome cooldown from summer weather—and beautiful scenery to boot. Why wait for New Year's when the weather is likely to be less inspiring? Make a new-you exercise resolution right now: Resolve to enjoy the glories of autumn through simple, calorie-burning activities.

Tips for Autumn Activities

The best exercises for you are activities that you enjoy—and will keep doing. Aim for 30 minutes a day, most days of the week. These ideas can help you get started:

♥ **Walk everywhere.** Walk around your neighborhood to enjoy the fall colors and weather. Just a 10-minute walk after every meal adds up to 30 minutes a day. Walk the dog, walk with a friend, walk to the store from the farthest parking place in the lot.

♥ **Get out and garden.** Rake leaves, prune your plants, trim the hedges, and pick up trash from the yard. It all counts as exercise.

♥ **Put the "work" into your workout.** Who says spring cleaning can't happen in the fall? Wash the windows, wash and wax the car, sweep the sidewalks. When the work's done, run around with your kids in the yard or at the park. Showing young people that exercise is fun is one of the best gifts you can give them.●

If you know of a community group interested in a Heart Health educational program, contact the Heart Center at 203-575-1992.

Raghuraman Vidhun, M.D.

Welcome, Dr. Vidhun!

The Heart Center of Greater Waterbury welcomes Raghuraman Vidhun, M.D., to the team! Dr. Vidhun joined the practice of Cardiology Associates of Waterbury in July and is now providing Interventional Cardiology Services at both Saint Mary's Hospital and Waterbury Hospital. Dr. Vidhun trained at Saint Vincent Catholic Medical Center, Mount Sinai Hospital and Bronx VA Medical Center in New York City and received his medical degree from Rajah Muthiah Medical College and Hospital in India. He is Board Certified in Internal Medicine and Cardiovascular Medicine.

THE BEAT GOES ON

Message from the Executive Director

Loraine C. Shea
Executive Director,
Heart Center of
Greater Waterbury

In a month traditionally devoted to matters of the heart, we bring to you our spring issue of "The Beat Goes On." Although keeping informed about issues of the heart is a good idea all year round, February is especially dedicated to this purpose. This issue will focus on two of your neighbors who were diagnosed with Valvular Heart Disease. Although less common than Coronary Artery Disease, this type of heart condition may require significant treatment. Thanks to early recognition of symptoms and the excellent treatment provided by cardiac surgeons and the cardiac team at the Heart Center of Greater Waterbury at Saint Mary's Hospital and Waterbury Hospital, these local community members are home with their loved ones and back to full and active lives. Share this issue with someone close to your heart!

Dixie and Steve Lafo of Naugatuck. Steve had mitral valve repair surgery at Saint Mary's Hospital.

Repairing Heart Valves

When a stethoscope is held to your chest, your doctor is listening to the blood travel throughout the four chambers of your heart. Each of these chambers has a valve that acts like a door to allow the blood into and out of the chamber in the right way. When a heart valve is not functioning properly, the normal rhythm of blood flowing through the heart may cause significant health problems.

As a teenager, Steven Lafo of Naugatuck was diagnosed with a Mitral Valve Prolapse, sometimes called a "heart murmur." Until a sudden episode of shortness of breath brought him to the emergency room in October 2007, he had lived a "perfectly normal life." But when he saw his family doctor this time, the murmur had worsened and an echocardiogram was ordered. Ragu Vidhun, MD, Interventional Cardiologist at the Heart Center of Greater Waterbury, examined the test results and diagnosed a severe problem with the mitral valve. Steven had led an active and busy life, "so finding out that valve surgery was necessary was quite a surprise." His mitral valve repair surgery was performed at Saint Mary's Hospital by Cardiothoracic Surgeon Paul Preissler, MD, just days after the initial diagnosis. For Steven the surgery

IN A HEARTBEAT:

ARE PALPITATIONS CAUSE FOR CONCERN?

You've probably felt your heart race or experienced a fluttering feeling in your chest once or twice. For most people, these episodes of abnormal heartbeat, or arrhythmia, are harmless. For some people, however, such symptoms may signal atrial fibrillation—a serious arrhythmia that requires medical attention.

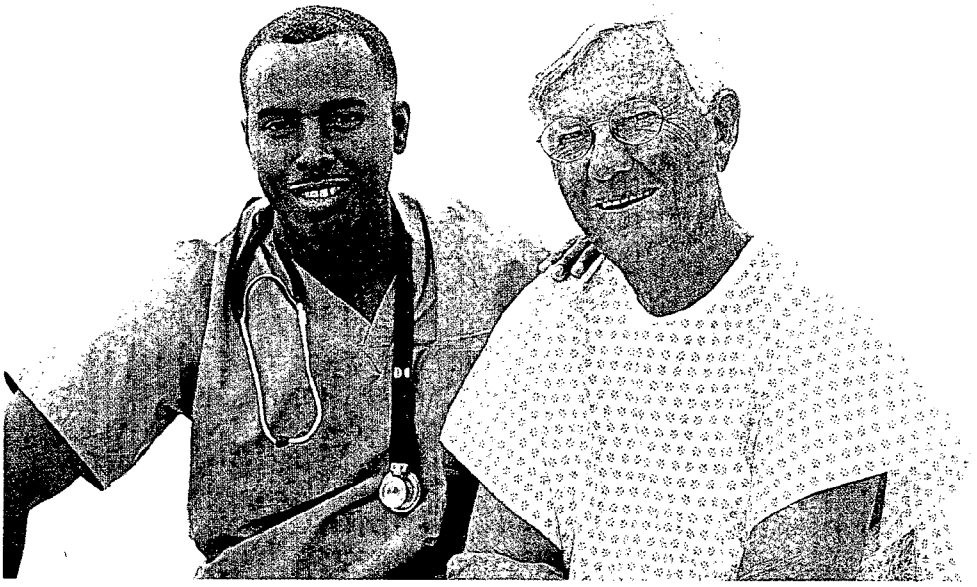
What Is Fibrillation?

Normally, the four chambers of the heart work like a well-timed machine. The two atria pump blood into the two ventricles, which then pump blood to the body. But during atrial fibrillation, the atria beat so rapidly and irregularly that they quiver. This causes blood to pool in the chambers and form clots—which may travel to the brain, resulting in a stroke.

Symptoms, Causes, and Risk Factors

The sensation of a fast and irregular heartbeat is a common symptom of atrial fibrillation. Other symptoms include dizziness, faintness, shortness of breath, and chest pain.

Often there is no known cause for atrial fibrillation. Men are at higher risk than are women, and the prevalence of the problem increases with age. These medical conditions can increase risk:



- ♥ Diabetes
- ♥ High blood pressure
- ♥ Congestive heart failure
- ♥ Heart disease

Diagnosis and Treatment

Experts recommend that you check with your doctor if you have any concerns about your heart rhythm or symptoms. To diagnose your condition, the doctor may order a painless test called electrocardiography that records the electrical activity of the heart.

If you have atrial fibrillation, your doctor may try to restore the normal rhythm of the heart by electrical stimulation. You may also need to take aspirin or another medication to reduce your risk of stroke.●

You can learn more about heart disease by logging on to the Heart Center of Greater Waterbury website at www.heartcentergw.org and clicking on "Heart Health Education."

0157
09/15/08

Joanne Pullaro, an RN and Case Manager at Waterbury Hospital, and a heart surgery patient.

helped him to return to a normal routine in just six weeks. Back to work by early December, Steven joined the Outpatient Cardiac Rehab Program at Saint Mary's Hospital to help improve his overall stamina. "I didn't know until Dr. Vidhun told me that I could have heart surgery at Saint Mary's Hospital. The care I received there was excellent. All the nurses were great."

There are several causes of heart valve problems, including small birth defects that have not been repaired, weakening or hardening of valves due to aging, and disease processes that may scar or damage a valve. In Steven's case, his mitral valve had weakened over time and was in need of repair.

There are also several types of valve dysfunction, each resulting in its own unique problem for the patient with valve disease. A heart valve with stenosis does not open enough to let enough blood pass through the chamber; a heart valve with regurgitation does not close correctly and may let blood leak into areas where it does not belong; and a heart valve with prolapse does not close properly, which can result in a small leak.

Joanne Pullaro, a Registered Nurse for 34 years at Waterbury Hospital, is well educated on heart disease. But after a vacation with her husband to Egypt, Joanne thought that she was just tired and coming down with a cold. She didn't immediately connect these symptoms to a Mitral Valve Prolapse diagnosis she had received as a young adult. She didn't make the connection until severe shortness of breath brought her to her family doctor, who recommended an echocardiogram and follow-up by her cardiologist. Working as a critical care nurse and more recently as a Case Manager on the Cardiovascular Unit, she knew where to turn when she learned that surgery for her valve disease was an option. "When I found out I needed valve surgery I had no doubt in my mind that I wanted to have it at Waterbury Hospital. I had all the confidence I needed in the skills of the surgeons and nursing staff. I recuperated quickly and have continued to work and travel."

The most common way to screen for issues with heart valves is by listening to the heart through the stethoscope. Although most murmurs are not indicative of cardiac disease, in some instances if a physician identifies a "murmur," it may be important in diagnosing undetected heart valve problems. Steven has relayed his heart surgery story to many of his friends and has been surprised by the number of people who tell him they were also diagnosed with a heart murmur. "I tell them to be sure to follow up with a cardiologist to get it checked regularly so you can avoid problems." Joanne also has advice for the patients she sees in the hospital: "Everyone is different but if the surgery is right for you, it can really help you to live a full and normal life. I felt so much better once the surgery was done."

For some people with Valvular Heart Disease, regular medical checkups and advice may be all that is needed. For others with more severe damage like Steven and Joanne, valve surgery was the treatment of choice.●

Diabetes and Heart Health— How They're Connected

Diabetes is a lifelong disorder that can have serious effects on almost every part of the body, including the heart. In fact, one of the key concerns for people with diabetes is keeping their blood sugar under control to reduce their risks for complications, such as heart disease.

A Higher Risk of Heart Problems

People with diabetes are two to four times likelier than people without diabetes to have heart disease. In addition, people with diabetes have the same high risk for heart attack as people without diabetes who already have had a heart attack.

Keeping It Under Control

If you have diabetes, you can take steps to protect your heart. Experts offer these recommendations:

- ♥ Eat a healthy diet.
- ♥ Exercise. Aim for 30 minutes of activity on most days of the week.
- ♥ Don't smoke. Smoking doubles the risk of heart disease.
- ♥ Keep your blood sugar under control. You should get a hemoglobin A1c test at least twice a year.
- ♥ Control high blood pressure, and have it checked at every doctor's visit.

- ♥ Lose weight if you are overweight.
- ♥ Ask your doctor if you should take a low-dose aspirin daily to lower your risk for heart disease.●

See the Upcoming Events column on page 2 for information on a scheduled series of FREE seminars on prevention and detection of diabetes.

THE BEAT GOES ON

Message from the Executive Director

Loraine C. Shea
Executive Director,
Heart Center of
Greater Waterbury

The Heart Center of Greater Waterbury takes pride not only in the clinical care it has provided to more than 2,400 hearts since July, 2005, but also in its mission to serve the community with outreach and education related to heart health. In this issue of "The Beat Goes On" we feature one very special community outreach event that took place in March. Because keeping you healthy is what we are all about, you are invited to attend our monthly support group and other educational sessions offered in many of the surrounding communities. Visit our web site at www.heartcentergw.org or refer to your local newspaper for all of our presentations and events, which are free to the public. We look forward to meeting you and providing you with the information you need to stay heart-healthy.

Every Heart Matters!

Heart Center staff members Beth Grant, EP, and Denise Konnick, RN, with community member Ron Accousti.

On Saturday, March 15, 2008, every heart mattered! Several hundred greater Waterbury community members attended a free heart health fair at the Brass Mill Center that was organized and staffed by the Heart Center of Greater Waterbury.

"In addition to providing lifesaving advanced cardiac care at both Saint Mary's Hospital and Waterbury Hospital, the Heart Center is committed to community outreach and education," said Loraine Shea, the Heart Center's Executive Director. "We provided free screenings, because it's important for individuals to identify their risk factors for heart disease in an effort to prevent heart disease before it starts."

Staff from all areas of the Heart Center volunteered their time for this community event. They provided free screenings and insight into several risk factors for heart disease. With an emphasis on increasing knowledge and thus prevention of disease, Heart Center staff interacted with more than 200 community members. Blood pressure screenings and cholesterol screenings performed by Heart Center Nurses were among the services provided to local community members during the event. "It's important for people to know their numbers as it pertains to their own blood pressure and cholesterol. Without the screening, many people just don't realize how at risk they may be," offered Sandy Micalizzi, Community Outreach Nurse for the Heart Center. "Once you know your numbers you can take action if needed."

Healthy eating, exercise and body fat measurements were another focus of the event. Clinicians from Cardiac Rehab and Registered Dieticians provided information on healthy nutrition choices, diabetes education and

KEEPING TRIGLYCERIDE LEVELS IN CHECK

Triglycerides are usually measured in the same blood test that determines cholesterol. But, according to a recent survey by the National Lipid Association (NLA), fewer than four in 10 Americans were aware of this fact. Indeed, cholesterol gets most of the publicity. But, like harmful low-density lipoprotein (LDL) cholesterol, excessive triglycerides in your blood can clog your arteries, boosting the risk for heart disease and stroke, particularly in women.

In fact, most of the fat we eat is in the form of triglycerides. And triglycerides also form the biggest share of body fat. The National Heart, Lung, and Blood Institute recommends that triglyceride levels be below 150 mg/dL.

As with high cholesterol, you can have elevated triglycerides without any symptoms. And high triglycerides and high cholesterol usually coincide.

In contrast, a healthy lifestyle, including regular exercise and a balanced diet, can help keep triglycerides in check. For example, a recent study in *Diabetes Care* revealed that eating less meat and more low-fat dairy products, vegetables, fruits, and whole-grain cereals helped a group of overweight people with metabolic syndrome lose weight and lower their triglycerides.

If you have diabetes, be sure to keep your blood sugar controlled because high blood sugar elevates triglyceride levels. If you have a high triglyceride level, the same medication used to lower high cholesterol can bring it down. ●

maintaining or increasing activity levels for improved health.

Because the Heart Center is here in Waterbury for prevention as well as treatment of heart disease, the program has a huge commitment to community outreach and education.

Although this event reached out to large numbers in the community, there are smaller programs offered at various locations in the greater Waterbury area every week. "We are very fortunate to have a community outreach nurse on our staff," said Shea. "On any given day Sandy can be found in Wolcott, Prospect, Southbury, Waterbury or Naugatuck. Leaders at local churches, schools, civic groups and senior centers just call to put in a request to the Heart Center and Sandy sets a date and puts them on the community schedule, which is located on our website. She is out informing the public, getting community members to think about healthy lifestyles and acting as a link to the clinical services available." This heart health fair was an extension of the education already provided.

A tremendous day was had by all. But for Heart Center staff and physicians all were in agreement that the highlight of the event was reconnecting with former patients! Several community members who received cardiac services at Saint Mary's Hospital or Waterbury Hospital in the recent past reconnected with some of their caregivers at this community event. They expressed sincere gratitude for the ongoing services provided locally.●

To arrange a heart-healthy education presentation for your community group, call Sandy Micalizzi at 203-575-5573.

From top: Rose Cuffee, RN, and Doret Lindo; Denise Clark, RN, and Joanne Prasauckas, RN; Monica Giacomi, RN, and Paula Connolly, along with her daughters; and Diane Hardt, RN, and Margery Ruchenbach-Goad.

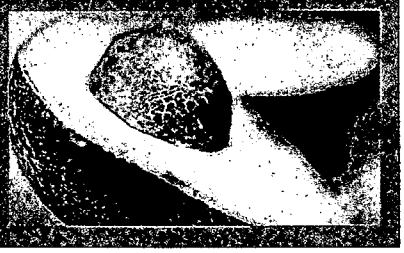
Eat Healthy Foods

Do you think that healthy foods are boring and have little flavor? Then try these simple, tasty foods that can help guard your heart health and possibly protect against some cancers, too.



♥ Almonds. Eat them for a healthy snack. They're also a great addition to salads and stir-fry dishes.

♥ Avocados. Add to a salad or use for a dip or side dish.

♥ Garlic. This is a flavorful way to season food without adding fat.

♥ Soy. Sample its many forms, such as tofu, soy milk, and soy nuts.

♥ Fruits and vegetables. They're nature's gift of good health.

This Summer, Take Safer Exercise to Heart

Regardless of the time of year, regular exercise plays an important role in keeping yourself healthy, fit, and in good management of your coronary artery disease (CAD).

Heat Hazards

If your body is too hot for too long, you could develop heat stroke, a kind of heat-related illness that can be deadly. Having CAD raises your risk for heat stroke.

In addition, certain heart medicines called beta-blockers can make you more likely to get lightheaded in the heat. This type of heat-related illness is called heat syncope.

Use Caution When It's Warm Out

If you have CAD and have your doctor's OK to exercise, it's wise to approach summertime workouts with a little extra care.

Other Summer Exercise Tips

♥ Schedule outdoor activities when it's cooler: in the morning and evening.

♥ Keep an eye on weather reports so you can plan ahead. Walk in the mall or exercise along with a fitness video at home.

♥ When you're active, drink two to four glasses (16 to 32 ounces) of fluid every hour. Also, stay away from drinks with caffeine, which can make you lose more fluids.

♥ Stop and rest if exercising in the heat makes your heart pound and breathing difficult.

Also, be aware of the signs of heat-related illness: headache, dizziness, nausea, or confusion. If this happens, find an air-conditioned place to rest and have a drink. If you don't cool down quickly, call your doctor or get emergency help.

♥ To learn more about cardiac health, log on to www.heartcentergw.org.

APPENDIX 4.

Waterbury Healthcare Delivery System
Preliminary Integration Plan

Waterbury Healthcare Delivery System

Appendix 4

Preliminary Integration Plan

	Pre-Merger	I. Planning Through First 180 Days		II. Stabilization and Prioritized Integration		III. Consolidation and Optimization			
		Year 1				Years 2-5			
Major Activities		Q1	Q2	Q3	Q4	2	3	4	5
Estimate resource requirement pre and post-merger by department and year									
Evaluate all major purchased service contracts to determine synergies and potential changes to operations									
Evaluate risks and key contingencies									
Develop IT Integration Plan									
Evaluate current technologies, providers, and anticipated IT requirements									
Determine recommended IT integration solutions for all major administrative and clinical systems									
Conduct prioritized RFI/RFP process for major vendors									
Determine timing and financial implications of IT Integration Plan									
Complete Facility Master Plan									
Conduct a 10 year master facility plan assuming no major new hospital facility using merger integration assumptions									
Evaluate options									
Determine sequencing and estimated capital requirements									
Seek approval for master plan and begin implementation planning									
Develop Detailed Five Year Financial Plan									
Conduct operational benchmarking and develop labor and non-labor targets by department that tie to the operating plan									
Develop five year capital plan									
Develop a five year volume, operating expense, and revenue forecast based on known assumptions									
Develop Milestone Plan with Performance Targets									
Kick-off First 180 Days Action Teams									

DRAFT Plan

Excerpt - TWH SMH presentation to State of CT Commissioners, March 2008

1. PREAMBLE and INTRODUCTION

1.1. Preamble

It is important that the medical profession play a significant role in critically evaluating the use of diagnostic procedures

Downloaded from circ.ahajournals.org by on August 4, 2008

0177
09/15/08

and therapies in the management or prevention of disease states. Rigorous and expert analysis of the available data documenting relative benefits and risks of those procedures and therapies can produce helpful guidelines that improve the effectiveness of care, optimize patient outcomes, and favorably affect the overall cost of care by focusing resources on the most effective strategies.

The American College of Cardiology (ACC) and the American Heart Association (AHA) have jointly engaged in the production of such guidelines in the area of cardiovascular disease since 1980. This effort is directed by the ACC/AHA Task Force on Practice Guidelines, whose charge is to develop and revise practice guidelines for important cardiovascular diseases and procedures. Experts in the subject under consideration are selected from both organizations to examine subject-specific data and write guidelines. The process includes additional representatives from other medical practitioner and specialty groups where appropriate. Writing groups are specifically charged to perform a formal literature review, weigh the strength of evidence for or against a particular treatment or procedure, and include estimates of expected health outcomes when data exist. Patient-specific modifiers, comorbidities, and issues of patient preference that might influence the choice of particular tests or therapies are considered, as well as frequency of follow-up and cost-effectiveness. When available, information from studies on cost will be considered; however, review of data on efficacy and clinical outcomes will be the primary basis for preparing recommendations in these guidelines.

The ACC/AHA Task Force on Practice Guidelines makes every effort to avoid any actual or potential conflicts of interest that might arise as a result of an outside relationship or personal interest of a member of the writing panel. Specifically, all members of the writing panel are asked to provide disclosure statements of all such relationships that might be perceived as real or potential conflicts of interest. These statements are reviewed by the parent task force, reported orally to all members of the writing panel at the first meeting, and updated as changes occur. The relationships with industry information for the writing committee members is posted on the ACC (www.acc.org) and AHA (www.americanheart.org) World Wide Web sites with the full-length version of the update (Appendix 1), along with names and relationships with industry of the peer reviewers (Appendix 2).

These practice guidelines are intended to assist healthcare providers in clinical decision making by describing a range of generally acceptable approaches for the diagnosis, management, or prevention of specific diseases or conditions. These guidelines attempt to define practices that meet the needs of most patients in most circumstances. The ultimate judgment regarding care of a particular patient must be made by the healthcare provider and patient in light of all of the circumstances presented by that patient.

The ACC/AHA 2004 Guideline Update for CABG was approved for publication by the ACCF Board of Trustees in March 2004 and the AHA Science and Advisory Coordinating Committee in June 2004. The summary article, describing the major areas of change reflected in the update, is published in the August 31, 2004 issue of *Circulation* and the September 1, 2004 issue of the *Journal of the American College of Cardiology.* The full-text guideline is posted on the ACC (www.acc.org) and the AHA (www.americanheart.org) World Wide Web sites. These guidelines will be reviewed 1 year after publication and yearly thereafter and considered current unless the Task Force on Practice Guidelines revises or withdraws them from circulation.

Elliott M. Antman, MD, FACC, FAHA
Chair, ACC/AHA Task Force on Practice Guidelines

1.2. Introduction

The ACC/AHA Task Force on Practice Guidelines was formed to make recommendations regarding the appropriate use of diagnostic tests and therapies for patients with known or suspected cardiovascular disease. Coronary artery bypass graft (CABG) surgery is among the most common operations performed in the world and accounts for more resources expended in cardiovascular medicine than any other single procedure. Since the initial guidelines for CABG surgery were updated and published in 1991 (1), there has been additional evolution in the surgical approach to coronary disease while at the same time there have been significant advances in preventive, medical, and percutaneous catheter approaches to therapy.

The current Writing Committee was charged with updating the guidelines published in 1999 (1a). The Committee reviewed pertinent publications, including abstracts, through a computerized search of the English literature since 1999 and performed a manual search of final articles. Special attention was devoted to identification of randomized trials published since the original document. A complete listing of all publications covering coronary bypass surgery in the past 4 years is beyond the scope of this document. However, evidence tables were updated to reflect major advances over this time period. Inaccuracies or inconsistencies present in the original publication were identified and corrected when possible. Recommendations provided in this document are based primarily on published data. Because randomized trials are unavailable in many facets of coronary artery disease (CAD) treatment, observational studies and, in some areas, expert opinion form the basis for recommendations that are offered. In each section of the Indications (Section 9), the relative levels of evidence favoring the Class I, II, and III indications were noted.

All of the recommendations in this guideline update have been written in full sentences that express a complete thought, such that a recommendation, even if separated and presented apart from the rest of the document, would still convey the full intent of the recommendation. It is hoped that this will increase readers' comprehension of the guidelines. Also, the level of evidence, either an A, B, or C, for each recommendation is now provided.

Downloaded from circ.ahajournals.org by on August 4, 2008

0178
09/15/08

Classification of Recommendations and Level of Evidence are expressed in the ACC/AHA format as follows and described in more detail in Table 1.

Classification of Recommendations

Class I: Conditions for which there is evidence and/or general agreement that a given procedure or treatment is beneficial, useful, and effective.

Class II: Conditions for which there is conflicting evidence and/or a divergence of opinion about the usefulness/efficacy of a procedure or treatment.

Class IIa: Weight of evidence/opinion is in favor of usefulness/efficacy.

Class IIb: Usefulness/efficacy is less well established by evidence/opinion.

Class III: Conditions for which there is evidence and/or general agreement that a procedure/treatment is not useful/effective and in some cases may be harmful.

Level of Evidence

Level of Evidence A: Data derived from multiple randomized clinical trials or meta-analyses.

Level of Evidence B: Data derived from a single randomized trial, or nonrandomized studies.

Level of Evidence C: Only consensus opinion of experts, case studies, or standard-of-care.

The Committee consists of acknowledged experts in cardiac surgery, interventional cardiology, general cardiology, and family practice. The Committee included representatives from the American Academy of Family Physicians (AAFP) and the Society of Thoracic Surgeons (STS). Both academic and private practice sectors were represented. The document was reviewed by 3 outside observers nominated by the ACC, 3 outside reviewers nominated by the AHA, and outside reviewers nominated by STS and the Society of Cardiovascular Anesthesiologists. This document was approved by the American College of Cardiology Foundation's Board of Trustees and the American Heart Association's Science Advisory and Coordinating Committee, as well as endorsed by the American Association for Thoracic Surgery and the Society of Thoracic Surgeons.

These guidelines overlap several previously published ACC/AHA guidelines, including those for the management of acute myocardial infarction (MI), for the management of stable angina, for percutaneous coronary intervention (PCI), and for exercise testing. For each of these guidelines, an analysis of overlap or contradiction has been explored by the Committee with attempts to create consensus in each instance. Finally, it is acknowledged that no guideline can take into account all of the various parameters that must be part of the individual decision to recommend CABG for a single patient. However, this entire report is intended to provide a framework that healthcare providers can use in combination with other types of knowledge and patient preferences to make rational decisions about treatment.

2. GENERAL CONSIDERATIONS AND BACKGROUND

Surgical revascularization for atherosclerotic heart disease is one of the great success stories in medicine. Relief of angina after revascularization, improvement in exercise tolerance, and the realization of survival benefit have attended the operation since the early stages of development. The evolution of coronary surgery is a story of focused thought, dedication, courage, collaboration, and serendipity.

Alexis Carrel (1872 to 1944) understood the association between angina pectoris and coronary stenosis (2). Before World War I, he had developed a canine model of aortocoronary anastomosis using carotid arteries as a conduit. For his seminal work in the development of cardiovascular surgical techniques, he was awarded the Nobel Prize. Carrel's contributions lay fallow, as he had predicted, until a time when advances in technology would allow safe application to humans.

Carrel and the aviator Charles Lindbergh collaborated in the 1930s in developing a primitive heart-lung machine intended to allow direct cardiac operation. Lindbergh was driven to this project by the desire to save a family member dying of valvular heart disease. The project did not produce a clinically useful device, but it did make incremental progress toward the ultimate goal (3). Over a professional lifetime of intense dedication, John Gibbon developed a clinically useful cardiopulmonary bypass (CPB) technology and applied it successfully to a patient in 1953 (4).

With direct coronary operation awaiting advancing techniques, surgical efforts to relieve angina pectoris in the mid-20th century included suppression of metabolic stimulation through thyroidectomy and augmentation of noncoronary flow to the myocardium through creation of pericardial or omental adhesions. Attempts to create an artificial collateral by implantation of the internal mammary artery (IMA) into the myocardium, the Vineberg procedure, met with limited success (5).

Coronary surgery moved into the modern era in the 1950s. It is not entirely clear to whom credit should be given for the first coronary bypass. The first direct surgical approach to the coronary circulation in a patient was likely performed by William Mustard in 1953 in Toronto, who used a carotid-to-coronary bypass. The patient did not survive the operation.

The first clinical use of the IMA to graft a coronary vessel appears to have been in response to an intraoperative misadventure. William Longmire applied the technique of coronary endarterectomy in a series of patients in 1958. A right coronary artery disintegrated during one of these operations, and an IMA was placed as a direct graft to restore flow. In retrospect, the surgeon thought it to be a good operation (2).

Table 1. Applying Classification of Recommendations and Level of Evidence

"Size of Treatment Effect"

"Estimate of Certainty (Precision) of Treatment Effect"

	Class I *Benefit >>> Risk* Procedure/Treatment SHOULD be performed/administered	Class IIa *Benefit >> Risk* *Additional studies with focused objectives needed* IT IS REASONABLE to perform procedure/administer treatment	Class IIb *Benefit ≥ Risk* *Additional studies with broad objectives needed; Additional registry data would be helpful* Procedure/Treatment MAY BE CONSIDERED	Class III *Risk ≥ Benefit* *No additional studies needed* Procedure/Treatment should NOT be performed/administered SINCE IT IS NOT HELPFUL AND MAY BE HARMFUL
Level A *Multiple (3-5) population risk strata evaluated** *General consistency of direction and magnitude of effect*	• Recommendation that procedure or treatment is useful/effective • Sufficient evidence from multiple randomized trials or meta-analyses	• Recommendation in favor of treatment or procedure being useful/effective • Some conflicting evidence from multiple randomized trials or meta-analyses	• Recommendation's usefulness/efficacy less well established • Greater conflicting evidence from multiple randomized trials or meta-analyses	• Recommendation that procedure or treatment not useful/effective and may be harmful • Sufficient evidence from multiple randomized trials or meta-analyses
Level B *Limited (2-3) population risk strata evaluated** *Limited consistency of direction and magnitude of effect*	• Recommendation that procedure or treatment is useful/effective • Limited evidence from single randomized trial or non-randomized studies	• Recommendation in favor of treatment or procedure being useful/ effective • Some conflicting evidence from single randomized trial or non-randomized studies	• Recommendation's usefulness/efficacy less well established • Greater conflicting evidence from single randomized trial or non-randomized studies	• Recommendation that procedure or treatment not useful/effective and may be harmful • Limited evidence from single randomized trial or non-randomized studies
Level C *Very limited (1) population risk strata evaluated** *Considerable inconsistency of direction and magnitude of effect*	• Recommendation that procedure or treatment is useful/effective • Only expert opinion, case studies, or standard-of-care	• Recommendation in favor of treatment or procedure being useful/ effective • Only diverging expert opinion, case studies, or standard-of-care	• Recommendation's usefulness/efficacy less well established • Only diverging expert opinion, case studies, or standard-of-care	• Recommendation that procedure or treatment not useful/effective and may be harmful • Only expert opinion, case studies, or standard-of-care
Suggested phrases for writing recommendations †	should is recommended is indicated is useful/effective/beneficial	is reasonable can be useful/effective/ beneficial is probably recommended or indicated	may/might be considered may/might be reasonable usefulness/effectiveness is unknown /unclear/uncertain or not well established	is not recommended is not indicated should not is not useful/effective/beneficial may be harmful

*Data available from clinical trials or registries about the usefulness/efficacy in different sub-populations, such as gender, age, history of diabetes, history of prior MI, history of heart failure, and prior aspirin use.

†In 2003, the ACC/AHA Task Force on Practice Guidelines developed a list of suggested phrases to use when writing recommendations. All recommendations in the CABG guideline update have been written in full sentences that express a complete thought, such that a recommendation, even if separated and presented apart from the rest of the document (including headings above sets of recommendations), would still convey the full intent of the recommendation. It is hoped that this will increase readers' comprehension of the guidelines and will allow queries at the individual recommendation level.

Michael DeBakey and Edward Garrett had a similar experience with a left anterior descending (LAD) coronary endarterectomy in 1964 (6). This situation was salvaged by an aortocoronary saphenous vein graft (SVG). The patient did well and had a patent aortocoronary SVG when restudied 8 years later. This experience was subsequently recorded and recognized as the first successful clinical aortocoronary SVG. An aortocoronary SVG operation by David Sabiston at Duke in 1962, involving an anastomotic end-to-end technique done without the use of CPB, was the first planned saphenous vein operation but was complicated by an early fatal outcome (7,8).

Mason Sones showed the feasibility of selective coronary arteriography and amassed a large library of cineangiograms that were studied in depth by Rene Favaloro (9). Sones and Favaloro formed an innovative team that demonstrated the efficacy and safety of SVG interposition and aortocoronary SVGs for single-vessel, left main, and multivessel coronary disease. An explosive growth in the application of these techniques ensued, such that within a decade, coronary bypass operation became the most frequent surgical procedure in the United States.

Recognition of the value of the IMA (also known as the internal thoracic artery) as a conduit came slowly. V.I. Kolessov, working in the 1960s at the Pavlov Institute in Leningrad, described a series of patients in whom the IMA was used for coronary revascularization without the aid of routine arteriography or CPB (10,11). Frank Spencer developed extensive experimental experience with the IMA to the coronary circulation in canine models. After preliminary animal and cadaveric work with microscopic methods, George Green brought this technique to successful clinical application. Floyd Loop and colleagues at the Cleveland Clinic incorporated the IMA into the coronary operation in a large series of patients and subsequently published the landmark article demonstrating the powerful survival benefit afforded by use of the IMA for LAD coronary distribution revascularization (12).

The 1970s, the first full decade of CABG, helped to define its appropriate role relative to medical therapy. Coronary bypass was found to consistently relieve angina and improve the quality of life in symptomatic patients. Three large, prospectively randomized, multicenter trials, The Coronary Artery Surgery Study (CASS), The Veteran's Administration Coronary Artery Bypass Trial, and the European Coronary Artery Bypass Trial, were conducted. These trials and several smaller studies helped to define subsets of patients likely to benefit from coronary bypass surgery in terms of prolongation of life and specifically identified patients with more advanced disease as those most appropriate for application of the operation for survival benefit. In addition to patients with triple-vessel disease and left main disease, patients with ischemic left ventricular (LV) dysfunction were found to benefit from the operation relative to medical therapy. These results led to the application of coronary bypass to progressively sicker patients in the 1980s.

Improvements in operative techniques and new technologies have allowed increasingly difficult patients to be approached with success. Improvements in cardiac anesthesia have paralleled improvements in operative techniques. Operation on complex patients became routine as sophisticated perioperative monitoring techniques, such as Swan-Ganz pulmonary artery catheters and intraoperative transesophageal echocardiography (TEE), were applied to specific problem situations. Anesthetic techniques, CPB technology, and most important, methods of myocardial protection were refined and successfully applied to specific problem situations. Close collaboration between the surgeon, the anesthesiologist, the perfusionist, and the intensive care team has been critically important to these advances. These refinements, discussed in Section 6, have led to an expected 30-day mortality of less than 1% in patients receiving elective coronary bypass who are less than 65 years of age and who have no severe LV dysfunction or congestive heart failure (CHF). Even in otherwise uncomplicated patients aged less than 65 years and with an ejection fraction (EF) of 0.25 to 0.35, first-time coronary bypass has an operative mortality risk of less than 5%.

In addition to improvements in short-term outcomes, evolving technology has contributed to improved long-term results. The widespread use of the IMA, the use of other arterial conduits, long-term antiplatelet therapy, and lipid management are discussed in later sections of these guidelines. Progress has also been significant in the moderation of perioperative morbidity. Central nervous system (CNS) injury, the systemic insults of CPB, infection, and bleeding are addressed in subsequent discussions. Finally, the application of CABG without CPB and through limited incisions has presented the prospect of further reductions in perioperative morbidity.

3. OUTCOMES

3.1. Hospital Outcomes

3.1.1. Introduction

As the clinician and the patient consider the decision for CABG, an understanding of probable immediate outcomes (events that occur during the immediate hospitalization or within 30 days of operation) is of paramount importance. In particular, it is important to be able to predict the hospital mortality of the procedure and the risk of the major complications of coronary bypass, including cerebrovascular accidents, major wound infection, and renal dysfunction.

3.1.2. Predicting Hospital Mortality

Class IIa

It is reasonable that statistical risk models be used to obtain objective estimates of CABG operative mortality. ***(Level of Evidence: C)***

Downloaded from circ.ahajournals.org by on August 4, 2008

The risk of death with CABG has been the focus of numerous studies in the last 2 decades. Although early reports were useful in correlating patient factors with outcomes such as in-hospital mortality (13), they were inadequate in their ability to risk stratify (14,15). Subsequently, a number of large single-center and multicenter cardiac surgical databases were established (13,16,17). From these databases, risk stratification models were created to better understand the variation in institutional and surgeon performance and to provide a more accurate risk prediction of mortality for patients facing CABG. Although all data sets identified patient and disease characteristics that consistently predicted mortality, the inclusion or exclusion of certain variables, variations in definitions of the same variables, and institutional and regional differences in practice styles have made it difficult to compare results across data sets. A review of 7 large data sets, representing more than 172 000 patients who underwent surgery between 1986 and 1994, was carried out to find the predictive power of certain preoperative variables (18). Seven core variables (i.e., urgency of operation, age, prior heart surgery, sex, LVEF, percent stenosis of the left main coronary artery, and number of major coronary arteries with more than 70% stenosis) were found to be predictive of mortality after CABG in all 7 data sets. Variables relating to the urgency of operation, age, and prior coronary bypass surgery were found to have the greatest predictive power, while variables describing coronary anatomy had the least predictive power. Besides these 7 core variables, 13 "level 1" variables were identified that, when added to the core variables, had a modest influence on the predictive capability of the model. These level 1 variables included the following: height; weight; PCI during index admission; recent (less than 1 week) MI; history of angina, ventricular arrhythmia, CHF, or mitral regurgitation (MR); comorbidities including diabetes, cerebrovascular disease, peripheral vascular disease (PVD), and renal dysfunction; and creatinine level. While the level 1 variables carry predictive power, their addition beyond these 7 core variables has been found to have a minimal impact on predictability (18).

While Jones and others have attempted to develop a common risk stratification language, general application of risk stratification models across populations must be done with caution. Although it may be possible to generalize the relative contribution of individual patient variables, rules must be calibrated to regional mortality rates and should be updated periodically to maximize accuracy (19,20). Table 2 compares the relative risk of the 7 core variables identified by Jones et al (18) as being most predictive of mortality as reported by 6 data sets.

Age has consistently predicted mortality after CABG (16,21), with advancing age associated with higher mortality. Assuming that age less than 65 years carries a relative risk of 1, Tu et al (22) found that the relative risk increased to 2.07 for patients between 65 and 74 years old and to 3.84 for those older than 75 years. Despite this increased short-term risk of mortality after CABG treatment, long-term results remain encouraging. When patients less than 50 years of age are compared with those 70 years and older and are matched by age to a population that did not undergo CABG, the older patients experience a longer hospitalization and higher hospital mortality, although their long-term survival more closely matches the general population compared with their younger counterparts. While elderly patients face an increased likelihood of morbidity after CABG and a particularly high incidence of stroke compared with the general population (23,24), age itself should not exclude a patient from being offered treatment with CABG, assuming that there is no prohibitive comorbidity. A careful quality of life and longevity assessment should be made in the oldest age groups.

Sex also predicts early mortality after CABG, with females facing an increased risk. Reported relative risks have ranged from 1.5 to 2.0. Smaller body size (25), smaller diameter of coronary arteries (26), increased age, and comorbidity status (27) have all been suggested as explanations for this increased risk. Another study based on the STS national database shows that female gender is an independent risk factor of operative mortality in low- and moderate-risk subsets but not in high-risk populations (28). Despite the increased risk, long-term results appear similar to those of males (29).

Having had previous open heart surgery adds considerable risk for patients having subsequent coronary artery surgery. The relative risk of early mortality appears to be around 3.0 compared with first-time CABG patients (16). An additional factor that further increases risk in this subset appears to be whether reoperation is carried out within 1 year of the primary operation (30). Despite the significant increased risk, long-term results after reoperative CABG are encouraging (31).

Coronary artery surgery in the presence of or immediately after an acute MI is controversial. Despite optimistic reports of low mortality if the operation is carried out within 6 hours of the onset of chest pain (32), many authors have found this approach to carry excessive mortality (33-35). Fibrinolytic therapy and/or PCI appears to be the preferable first-line therapy in the presence of an evolving MI. CABG surgery is reserved for patients with evidence of ongoing ischemia despite these interventions, or it may be performed coincident with repair directed at mechanical complications of infarction (i.e., ventricular septal defect or papillary muscle rupture). It also may benefit patients with shock complicating a recent acute MI, as demonstrated in the Should We Emergently Revascularize Occluded Coronaries for Cardiogenic Shock (SHOCK) trial (35a).

The presence of comorbidities is also related to survival after CABG. Though not identified by Jones et al (18) as a core variable, treated diabetes (36), the presence of PVD (37), renal insufficiency (38), and COPD have all been shown to have a negative impact on outcome after CABG.

An intraoperative variable that seems to have both a short-term and a long-term impact on survival is the use of the

NNE indicates Northern New England Cardiovascular Disease Study Groups; VA, Veterans Affairs cardiac surgical database; STS, Society for Thoracic Surgery national cardiac surgical database; NYS, New York State cardiac surgery reporting systems; CC = Cleveland Clinic; AGH = Allegheny General Hospital; LMD, left main disease; Vol, voluntary; reg, regional; Man, mandatory; nat, national; state, single state; SI, single institution; NA, not available; and mult reops, multiple reoperations.

The relative risk coefficient for age indicates the additional mortality risk per year of age greater than 50 years.

*Urgent indicates patients are required to stay in the hospital but may be scheduled and operated on within a normal scheduling routine; Emergent, ongoing refractory cardiac compromise, unresponsive to other forms of therapy except for cardiac surgery; and Salvage, ongoing cardiopulmonary resuscitation en route to

IMA as a bypass conduit. Loop, Lytle, and others have reported that use of the IMA is an independent predictor of survival 10 to 20 years after CABG (39,40). Hospital mortality after CABG has also been reported to be lower when the IMA is used (41,42).

In summary, early mortality after CABG is associated particularly with advancing age, poor LV function, and the urgency of operation. Additional coronary anatomic and comorbid conditions further influence risk. If overall risk for an institution or region is known, then a general estimate for the individual patient can be rendered preoperatively by using mathematical models, as illustrated in Table 3 and Figure 1. This application may find utility as patients and their physicians weigh the potential benefits versus risks of proceeding with bypass surgery.

3.1.3. Morbidity Associated With CABG: Adverse Cerebral Outcomes

Class I

Significant atherosclerosis of the ascending aorta mandates a surgical approach that will minimize the possibility of arteriosclerotic emboli. ***(Level of Evidence: C)***

Neurological abnormalities after CABG are a dreaded complication. The reported incidence ranges from 0.4% to nearly 80%, depending on how the deficit is defined (43-45). Neurological derangement after CABG has been attributed to hypoxia, emboli, hemorrhage, and metabolic abnormalities (46,47). Despite the many advances made in cardiac surgery, postoperative stroke remains a problem.

Postoperative neurological deficits have been divided into 2 types: type 1 deficits are those associated with major, focal

Table 3. Preoperative Estimation of Risk of Mortality, Cerebrovascular Accident and Mediastinitis

For use only in isolated CABG surgery

Directions: Locate outcome of interest, e.g., mortality. Use the score in that column for each relevant preop variable; then sum these scores to get the total score. Take the total score and look up the approximate preoperative risk in the table below.

Patient or Disease Characteristic	Mortality score	CVA score	Mediastinitis score
Age 60-69	1.5	1.5	1
Age 70-79	2.5	2.5	1.5
Age ≥80	6.5	3	2
Female sex	2	1.5	
Obesity (BMI 31-36)			2
Severe obesity (BMI ≥ 37)			4.5
Diabetes	1	1.5	1.5
COPD	2		2
PVD	1.5	1.5	
Dialysis	4	2	3
Creatinine ≥ 2	2	2	
MI ≤7 days	1.5		
Prior CABG	2.5		
EF < 40%	2	1.5	1.5
3-Vessel disease	1.5		
LM 50-89%	1.5		
LM ≥ 90%	2		
WBC >12K	2.5		
Urgent surg.	2	1.5	2
Emergency surg.	5	3.5	2
Total Score			

Preoperative Risk

Total Score	Mortality %	CVA %	Mediastinitis %
0	0.2	0.4	0.3
1	0.2		0.3
2	0.3	0.6	0.4
3	0.3	0.9	0.5
4	0.5	1.3	0.7
5	0.7	1.4	0.9
6	1.0	2.0	1.3
7	1.3	2.7	1.7
8	1.8	3.4	2.5
9	2.3	4.2	3.2
10	3.0	5.9	4.2
11	4.0	7.6	5.6
12	5.3	≥10.0	≥7.3
13	6.9		
14	8.8		
15	11.5		
16	14.1		
17	18.7		
18	≥23.0		

Calculation of Mortality Risk: An 80-year-old female, with an EF less than 40% who is having elective CABG surgery, has had no prior CABG surgery and has no other risk factors. Her total score = 6.5 (age greater than or equal to 80) + 2 (female sex) + 2 (EF less than 40%) = 10.5. Since her total score equals 10.5, round up to 11; her predicted risk of mortality = 4.0%.

Definitions:

Obesity: Find the approximate height and weight in the table below to classify the person as obese or severely obese. **Obesity:** BMI 31-36. **Severe obesity:** BMI greater than or equal to 37.

Example: A patient is 5'7" and weighing 200 lbs. is classified obese. If the patient weighed 233 lbs. or more, he/she would be classified severely obese.

Height (feet and inches)	Weight (lbs.) Obesity BMI 31-36	Weight (lbs.) Severe Obesity BMI≥37	Height (feet and inches)	Weight (lbs.) Obesity BMI 31-36	Weight (lbs.) Severe Obesity BMI ≥37
5'0"	158-186	≥187	5'8"	203-239	≥240
5'1"	164-192	≥193	5'9"	209-246	≥247
5'2"	169-199	≥200	5'10"	215-254	≥255
5'3"	175-205	≥206	5'11	222-261	≥262
5'4"	180-212	≥213	6'0"	228-268	≥269
5'5"	186-219	≥220	6'1"	235-276	≥277
5'6"	191-225	≥226	6'2"	241-283	≥284
5'7"	198-232	≥233	6'3"	248-291	≥292

Diabetes: Currently treated with oral medications or insulin.

COPD (chronic obstructive pulmonary disease): treated with bronchodilators or steroids.

PVD (peripheral vascular disease): Cerebrovascular disease, including prior CVA, prior TIA, prior carotid surgery, carotid stenosis by history or radiographic studies, or carotid bruit. Lower-extremity disease including claudication, amputation, prior lower-extremity bypass, absent pedal pulses or lower-extremity ulcers.

Dialysis: Peritoneal or hemodialysis-dependent renal failure.

MI less than 7 days: The development of a) new Q wave on EKG or b) new ST-T changes with a significant risc (defined locally) in CPK with positive (defined locally) isoenzymes.

EF less than 40% (left ventricular ejection fraction): The patient's current EF is less than 40%.

WBC greater than 12K (white blood cells greater than 12000): Use the patient's last preoperative measurement of WBC taken before the procedure.

Urgent: Medical factors require patient to stay in hospital to have operation before discharge. The risk of immediate morbidity and death is believed to be low.

Emergency: Patient's cardiac disease dictates that surgery should be performed within hours to avoid unnecessary morbidity or death.

Data set and definitions for dependent variables:

The regression models that generated the scores for these prediction rules were based on 14971 patients receiving isolated CABG surgery between 1999 and 2002. The dependent variables and observed event rates are as follows: inhospital mortality (2.5%); cerebrovascular accident, defined as a new focal neurologic event persisting at least 24 hours (1.6%); and mediastinitis during the index admission defined by positive deep culture and/or gram stain and/or radiographic findings indicating infection and requiring reoperation (1.0%).

Northern New England Cardiovascular Disease Study Group 4/03.
BMI indicates body mass index; CVA, cerebrovascular accident; LM, left main; TIA, transient ischemic attack; EKG, electrocardiogram.

Downloaded from circ.ahajournals.org by on August 4, 2008

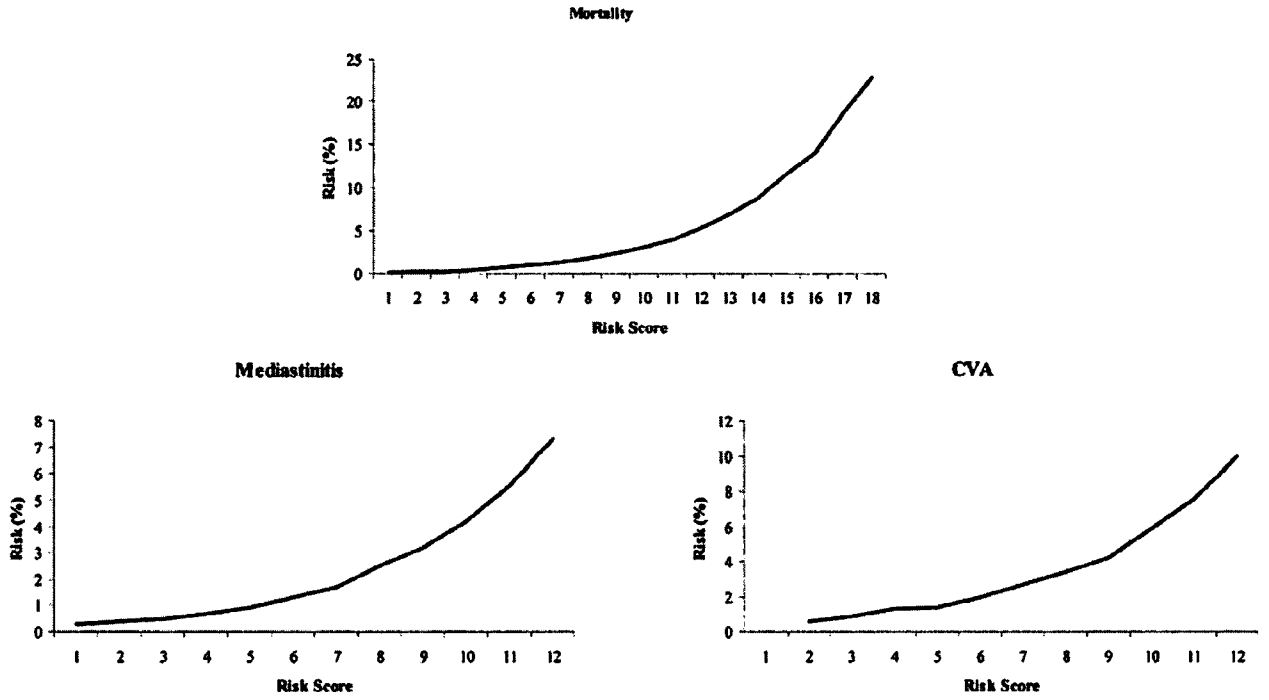

Figure 1. Event curves. For calculation of risk score, see Table 3.

neurological deficits, stupor, and coma; type 2 deficits are characterized by deterioration in intellectual function or memory. Roach et al (48) reported on a multi-institutional prospective study aimed at determining the true incidence of both stroke (type 1 deficits) and encephalopathy (type 2 deficits) after CABG. In this study, 2108 patients operated on at 24 institutions were observed for signs of neurological dysfunction after CABG. Adverse cerebral outcomes occurred in 129 patients (6.1%) and were evenly distributed between type 1 (3.1%) and type 2 (3.0%) deficits. The influence of these complications included a 21% mortality for those with type 1 deficits and a 10% mortality for those with type 2 deficits. In addition, patients with neurological complications had, on average, a 2-fold increase in hospital length of stay and a 6-fold likelihood of discharge to a nursing home.

Independent risk factors were identified for both type 1 and type 2 deficits (48). Predictors of both types of cerebral complications included advanced age, especially age greater than or equal to 70 years, and a history or the presence of significant hypertension. Both of these variables have previously been reported to be associated with adverse cerebral outcomes after CABG (49,50).

Predictors of type 1 deficits included the presence of proximal aortic atherosclerosis as defined by the surgeon at the time of surgery (odds ratio [OR] 4.52), a history of prior neurological disease (OR 3.19), use of the intra-aortic balloon pump (IABP; OR 2.60), diabetes (OR 2.59), a history of hypertension (OR 2.31), a history of unstable angina (OR 1.83), and increasing age (OR 1.75 per decade). Perioperative hypotension and the use of ventricular venting were also weakly associated with this type of outcome.

Proximal aortic atherosclerosis has been reported to be the strongest predictor of stroke after CABG, supporting the theory that liberation of atheromatous material during manipulation of the aorta is the main cause of this complication (49). Although palpation of the aorta has traditionally been used by surgeons to identify patients with atheromatous disease of the ascending aorta and to find "soft spots" for cannulation or cross-clamping, the use of ultrasound has been suggested as a more accurate means of assessing the aorta (51). Duda et al (51) have suggested that once aortic atherosclerosis is identified, alternative strategies to prevent mobilization of aortic atheroma should be considered, including techniques such as groin or subclavian placement of the aortic cannulas, fibrillatory arrest without aortic cross-clamping, use of a single cross-clamp technique, modifying the placement of proximal anastomoses, or all-arterial revascularization in cases of severe aortic involvement. Other authors recommended ascending aortic replacement under circulatory arrest as the best means of minimizing this complication (52,53).

A history of previous neurological abnormality or the presence of diabetes is also a predictor of type 1 CNS complications. These are likely markers for patients with marginal cerebral blood flow, alterations in CNS vasomotor autoregulatory mechanisms, or diffuse atherosclerosis. The need for an IABP is likely correlated with a higher risk of atheromatous emboli and is often required in patients with systemic hypoperfusion, each of which may cause stroke after CABG.

Downloaded from circ.ahajournals.org by on August 4, 2008

The fact that use of an LV vent—or other devices that have potential for introducing air into the arterial circulation—has been associated with stroke suggests air emboli as the cause and argues for meticulous technique when placing these devices to prevent this complication.

Factors predictive of type 2 neurological deficits include a history of alcohol consumption, dysrhythmia (including atrial fibrillation), hypertension, prior CABG, PVD, or CHF. Because aortic atherosclerosis is not a strong predictor of type 2 complications, encephalopathic changes may be related not only to microemboli but also to the brain's microcirculation. Type 2 complications are more likely to occur after periods of hypotension or inadequate perfusion.

Off-pump coronary artery bypass (OPCAB) avoids both aortic cannulation and cardiopulmonary bypass. Accordingly, one would expect postoperative neurological deficits to be reduced in patients undergoing OPCAB. Three randomized controlled trials (54-56) have not firmly established a significant change in neurological outcomes between OPCAB patients and conventional CABG patients. Each trial demonstrates problems inherent with small patient cohorts, differing definitions, and patient selection. At this point, there is insufficient evidence of a difference in neurological outcomes for patients undergoing OPCAB compared with those undergoing conventional CABG (57).

Individual patient counseling regarding postoperative stroke risk represents an important opportunity to assist patients as they weigh the risks and benefits of elective CABG. Although postoperative stroke rates may vary between hospitals or regions, if local rates are known, then these may be used to assist the patient in appreciating the general risk of this dreaded complication. Strategies to reduce the risk of postoperative neurological complications are discussed in depth in Section 4.1.1.

3.1.4. Morbidity Associated With CABG: Mediastinitis

Deep sternal wound infection has been reported to occur in 1% to 4% of patients after CABG and carries a mortality rate of nearly 25% (58,59). Studies have consistently associated obesity and reoperation with this complication, while other risk factors such as use of both IMAs, duration and complexity of operation, and the presence of diabetes have been reported inconsistently. Most studies examining deep sternal wound infection have been single-center, retrospective reviews, and variation in wound surveillance techniques and the definition of deep sternal wound infection limit comparisons.

Obesity is a strong correlate of mediastinitis after CABG (60). In one report of 6459 patients undergoing CABG at a single institution, Milano et al (61) found obesity to be the strongest independent predictor of mediastinitis (OR 1.3). In a prospective multi-institutional study, the Parisian Mediastinitis Study Group also found obesity to carry the greatest association with the development of postoperative mediastinitis (OR 2.44) (62). The mechanism by which obesity leads to this complication is poorly understood but is likely multifactorial. Perioperative antibiotics may be poorly distributed in adipose tissue, skin folds present a special challenge in maintaining sterility, and large regions of adipose tissue serve as an ideal substrate for bacteria and represent a clinical challenge for diagnosis when early infection occurs.

Another patient characteristic that has been associated with postoperative mediastinitis is the presence of diabetes (55,57), especially in patients requiring regular insulin (58). In addition to the microvascular changes seen in diabetic patients, elevated blood glucose levels may impair wound healing. The use of a strict protocol aimed at maintaining blood glucose levels less than or equal to 200 mg/dL by the continuous, intravenous infusion of insulin has been shown to significantly reduce the incidence of deep sternal wound infection in patients with diabetes (58a,314).

Prior cardiac surgery is another factor associated with the development of mediastinitis (61-63). Reoperation requires additional dissection, necessitates longer operative and/or perfusion times, produces more bleeding, and results in a higher likelihood of needing transfusion, variables that have all been linked to this complication.

Operator-dependent variables may also contribute to the development of deep sternal wound infection. These include the use of both IMAs for bypass conduits and excessive use of electrocautery for hemostasis (61,320). No studies have found the use of a single IMA to be predictive of mediastinitis. Two reports identified the use of both IMAs to be an independent predictor (62,62a), while several others have shown no correlation with the development of mediastinitis (58,61). Because the use of both IMAs may predispose to devascularization of the sternum, it seems likely that this technique promotes infection, especially when combined with other risk factors such as diabetes and/or obesity.

In summary, deep sternal wound infection after CABG is an expensive and potentially lethal complication that appears to have a multifactorial etiology. Strategies to reduce the incidence of this complication include meticulous aseptic technique, keeping perfusion times to a minimum, avoidance of unnecessary electrocautery, appropriate use of perioperative antibiotics, and strict control of blood glucose levels during and after operation. Each of these is discussed in greater depth in Section 4.1.4.

3.1.5. Morbidity Associated With CABG: Renal Dysfunction

The first major multicenter study of renal dysfunction after CABG surgery was published in 1998 (64). This study of 2222 patients who underwent myocardial revascularization with CPB defined postoperative renal dysfunction (PRD) as a postoperative serum creatinine level of greater than or equal to 2.0 mg/dL or an increase in the serum creatinine level of greater than or equal to 0.7 mg/dL from preoperative to maximum postoperative values. PRD occurred in 171 (7.7%) of the patients studied; 30 of these (18%, or 1.4% of

Downloaded from circ.ahajournals.org by on August 4, 2008

0186
09/15/08

all study patients) required dialysis. The mortality rates were 0.9% among patients who did not develop PRD, 19% in patients with PRD who did not require dialysis, and 63% among those who required dialysis.

Several preoperative risk factors for PRD were identified, including advanced age, a history of moderate to severe CHF, prior CABG, type 1 diabetes mellitus, and preexisting renal disease (preoperative creatinine levels greater than 1.4 mg/dL). The risk of PRD in patients less than 70 years of age nearly tripled with 1 preoperative risk factor and increased further with 2 risk factors. A detailed analysis of the impact of these preoperative risk factors for PRD for 3 age groups is presented in Table 4 (64). These findings allow identification of high-risk patients for PRD and a general estimation of the risk for PRD for an individual patient. The reported risk for patients with moderate renal dysfunction is consistent with previous reports from smaller, single-center studies (65-67).

Although data from large, multicenter studies are not available, it is reasonable to conclude that patients with more advanced, chronic, preoperative renal failure (but without end-stage renal disease [ESRD]) would have an even higher incidence of PRD requiring dialysis. Because their kidneys have a greater reduction in functioning nephrons than those in patients with lesser degrees of renal failure in the study cited above, they would be more vulnerable to the maldistribution of renal blood flow, an increase in renal vascular resistance, and the decreases in total renal blood flow and glomerular filtration rate that occur during CABG surgery (68-70). This conclusion has been supported by a study of 31 patients who underwent CABG with a baseline serum creatinine level greater than or equal to 1.6 mg/dL in the 6 months before surgery and who did not require preoperative dialysis (71). The mean age of the patients was 71 years, and nearly 80% were males. The hospital mortality was 19%, and 26% of surviving patients required chronic dialysis. Among 19 patients with a creatinine level greater than or equal to 2.6 mg/dL, 42% of survivors required chronic hemodialysis, whereas none of the surviving patients with a creatinine level less than or equal to 2.6 mg/dL required chronic dialysis. This study suggests that patients greater than 70 years old with a creatinine level greater than or equal to 2.6 mg/dL are at extreme risk for dialysis dependency after CABG, and alternative options for coronary management should be strongly considered.

The importance of perioperative renal function is emphasized by a report that correlated acute renal failure sufficient to require dialysis and operative mortality after cardiac surgery (72). The 42 773 patients who underwent CABG or valvular heart surgery at 43 Department of Veterans Affairs medical centers between 1987 and 1994 were evaluated to determine the association between acute renal failure suffi-

cient to require dialysis and operative mortality. This degree of acute renal failure occurred in 460 (1.1%) patients. Overall, operative mortality was 63.7% in these patients, compared with 4.3% in patients without this complication. Acute renal failure requiring dialysis was independently associated with early mortality after cardiac surgery, even after adjustment for comorbidity and postoperative complications.

3.1.6. Posthospital Outcomes

The extensive application of CABG has been a consequence of its effectiveness in the relief of angina and prolongation of survival in certain subsets. The 1999 Guidelines provided data that allow a general understanding of expectation after CABG (1). In a heterogeneous group of patients, survival at 5 years was 92% and at 10 years was 81%. Freedom from angina was 83% at 5 years and 63% at 10 years. The previous guidelines provided equations for predicting patient-specific outcomes, including freedom from unfavorable events, in a comparison of coronary bypass surgery versus medical treatment. These detailed predictive instruments remain appropriate for use and are not presented here. While a discussion of the comparative benefits of CABG versus medical therapy appears in Section 3.2, a brief description of the factors that influence the long-term results of the operation is appropriate here.

The predictors of long-term survival after CABG have been analyzed in a number of studies. In an analysis of 23 960 patients from 1977 to 1994 from Emory University, advanced age, EF, presence of diabetes, number of diseased vessels, and sex were significant multivariate predictors of survival, while angina class, hypertension, history of MI, renal dysfunction, and CHF were other important factors identified by univariate analysis (Table 5) (73). Other studies have identified predictors for the recurrence of angina and for postoperative MI (Table 6). Importantly, untoward events after coronary bypass tend to increase in frequency between 5 and 10 years after the operation, apparently coincident with the gradual occlusion of vein grafts. Approximately 50% of vein grafts are closed by 10 years after operation.

The delayed return of angina and the fact that approximately half of the survivors of CABG eventually die of cardiac-related causes identifies the "Achilles heel" of the procedure: late vein-graft atherosclerosis and occlusion. The most important surgical gain has been verification of excellent late patency with IMA grafts (74). From this encouraging result with the use of a single arterial graft has sprung the arterial arborization of today, with reports of multiple and "complete" arterial grafting (75-78). This is discussed further in Sections 4.2. and 6.2.

3.2. Comparison of Medical Therapies Versus Surgical Revascularization

Since the 1991 Guidelines, relatively little clinical trial information comparing medical with surgical treatment of CAD has been published. However, longer follow-up of

Table 7. Limitations of Randomized Trials in View of Current Practice

Patient Selection	Surgical Factors	Medical/Nonsurgical Therapy
Patients less than or equal to 65 years of age	Only 1 trial used arterial grafts (CASS) (in only 14% of patients)	Lipid-lowering therapy not used or standard
Only 1 trial included women (CASS)	Newer modalities of cardioprotection not used	Aspirin not widely used
Predominantly low-risk, stable patients	Minimally invasive, off-bypass techniques not used	Beta-blockers used in only half of patients
	Aspirin not routinely given early postoperatively	ACE inhibitor not used
		Coronary angioplasty not widespread

CASS indicates Coronary Artery Surgery Study; ACE, angiotensin-converting enzyme.

patients enrolled in the earlier, major randomized trials has solidified the appropriate indications for surgical treatment.

The traditional stratification of patients has been based on the extent of CAD (i.e., number of vessels with anatomically significant disease and whether or not the major epicardial obstruction is proximal) in association with the extent of LV dysfunction (determined by a simple measure of global LVEF). The major end point of the studies has been survival. The major randomized trials studied patients between 1972 and 1984, at which time the predominant medical therapy was the use of beta-blockers and nitrates.

There are several important limitations of the randomized trials in view of current practice (Table 7). In the ensuing years, calcium channel blockers have been added, particularly for symptomatic patients. The use of aspirin has become more widespread in all patients with CAD. The role of 3-hydroxy-3-methylglutaryl coenzyme A reductase inhibitors and other lipid-lowering agents has now been recognized as important in reducing recurrent ischemic events. Angiotensin converting enzyme inhibitors are now used routinely, particularly in patients with symptomatic heart failure after acute myocardial infarction or those with LV systolic dysfunction. It is hoped that these agents will be used equally in patients treated with medications alone and in patients after CABG surgery, whose revascularization therapy is complemented by appropriate medical treatment to reduce ischemic complications. The contribution of advances in surgical revascularization techniques cannot be fully assessed. The potential value of arterial conduits for revascularization, particularly the IMA, cannot be evaluated from these early randomized studies, yet their use is now routine in CABG surgery. There are also no prospective, randomized studies comparing the more recent off-bypass or minimally invasive surgical approaches to medical therapy. Finally, the randomized trials oversimplify the designation of 1-, 2-, and 3-vessel disease. Several reports show that prognosis is also critically related to the location of lesions within vessels, not simply the number of vessels involved (9,18).

3.2.1. Overview

There were 3 major randomized trials (79-81) and several smaller ones (82-84). These studies addressed similar clini-

cal questions and, as shown in Figure 2 and Figure 3, had similar outcomes. Much of the primary patient information for the 2649 patients enrolled in these randomized trials has been combined in a collaborative meta-analysis, which has facilitated comparison of outcomes at 5 and 10 years of follow-up (Table 8) (85). Extension of survival is a useful measure to compare different treatment strategies and can be adjusted for patient characteristics (Figure 4). Across all patients, the improvement in survival with CABG compared with medical treatment is 4.3 months at 10-year follow-up (*P* equals 0.003). In patients with left main disease, the survival benefit is 19.3 months. Subset analyses for other subgroups show statistical benefit for those with 3-vessel disease, and in those with 1- or 2-vessel disease including LAD CAD. Relative risk reductions were similar with abnormal or normal LV function. However, a similar relative risk reduction is associated with a greater absolute survival benefit in the high-risk population with depressed LV function. The survival benefit of CABG surgery for individuals with 1- and 2-vessel disease without LAD involvement is small, particularly in the setting of normal LV function. A higher clinical risk score, more severe angina, and a positive exercise test are associated with a greater prolongation of survival after CABG surgery than with medical therapy at 5 and 10 years (Table 8) (85). Two clinical scoring systems have been used. The Veterans Administration trial used the clinical variables of angina class, history of hypertension, and MI as well as the degree of ST-segment depression at rest. The Coronary Artery Bypass Graft Surgery Trialists' Collaboration (85) developed a stepwise logistic regression analysis-based risk score that included clinical and angiographic variables as well as EF (Tables 8-10) (85). Patients can be stratified according to these clinical criteria and by using these scoring systems. There was little survival benefit in those with a low risk (1% annual mortality) but increasingly significant survival extension in those at moderate (annual mortality of 2.5%) or high (annual mortality of 5%) risk.

The randomized trials provide robust results for the populations studied. However, there are important limitations in generalizing the results of these studies to most patients with coronary disease because of the way patients were selected for the randomized studies. Specifically, the mean age of randomized patients was 50.8 years, there were very few patients greater than 65 years, 96.8% were male, and only 19.7% had an LVEF less than 0.50 (85). The challenge of choosing a therapeutic option in patients with CAD is that the clinical course is highly variable, and the "average"

Downloaded from circ.ahajournals.org by on August 4, 2008

patient does not fit perfectly into 1 of the groups studied. The large registries (86-88) and other studies (89-91) provide useful confirmatory information in support of the clinical trials and, if interpreted with appropriate caution, can help in the subsets not well studied in the randomized trials. The following discussion combines information from randomized and nonrandomized trials in which the directional trends are consistent with the randomized information.

3.2.2. Location and Severity of Stenoses

3.2.2.1. Left Main Disease

The benefit of surgery over medical treatment for patients with significant left main stenosis is little argued. All of the trials define significant left main stenosis as being greater than 50% diameter stenosis as judged by contrast angiography. The median survival for surgically treated patients is 13.3 years versus 6.6 years in medically treated patients (92,93).

Left main equivalent disease, defined as severe (greater than or equal to 70%) diameter stenosis of the proximal LAD and proximal left circumflex disease, appears to behave similarly to true left main disease. Median survival for surgical patients is 13.1 years versus 6.2 years for medically assigned patients (92). However, there are few randomized or randomizable patients with this anatomy. By 15 years, there is less survival benefit for patients assigned to surgery. It is estimated that if all medical patients survived 15 years, 65% would eventually have surgery (85). At 15 years, cumulative survival in the CASS registry for patients with left main equivalent disease was 44% for surgical patients and 31% for the medical group (92,94,95).

3.2.2.2. Three-Vessel Disease

Significant CAD is defined variably in the major studies. CASS originally reported results with significant stenosis defined as greater than or equal to 70%. The Veterans Administration and European studies used 50% as the cutoff for significant stenosis, and when the studies were combined for the meta-analysis (85), the 50% criterion defined significant disease for all vessels. For the purposes of this guideline, unless otherwise specified, the term significant will indicate greater than 50% reduction in visual stenosis.

The outcome of patients with 3-vessel CAD assigned to surgical or medical treatment is similar at the 10-year follow-up to that reported earlier in randomized trials. The more severe the symptoms, the more proximal the LAD CAD, and the worse the LV function, the greater is the benefit from surgery (81,85,96-100). In patients with 3-vessel disease, the relative risk reduction for surgery at 5 years is 42% and at 10 years is 24%, with an increase in survival of 5.7 months at 10-year follow-up (85). The definitions of single-, double-, and triple-vessel disease in these guidelines are

those from the Bypass Angioplasty Revascularization Investigation (BARI) (101,102).

3.2.2.3. Proximal LAD Disease

Proximal LAD CAD (greater than 50% stenosis) is an important contributor to outcome. In patients with proximal LAD disease, the relative risk reduction of CABG is 42% at 5 years and 22% at 10 years. In LAD disease without proximal involvement, the relative risk reduction is 34% at 5 years and 10% at 10 years. In the presence of depressed LV function, the absolute benefit of surgery is greater because of the risk of this population (81,103).

3.2.2.4. LV Function

LV systolic function remains an important predictor of which patients are likely to benefit from surgery (97-99,104). In patients with a normal EF, surgical revascularization generally provides little survival benefit. In patients with mild to moderately depressed function, the poorer the LV function, the greater is the potential benefit of surgery (97-99,105,106). The relative benefit is similar, but there is greater absolute benefit because of the high-risk profile of these patients. It is important to note that the randomized trials did not include patients with an LVEF less than 0.35. Thus, many of the patients operated on today were not well represented in the randomized trials.

A major growth in our understanding of the potential reversibility of chronic systolic dysfunction among patients with CAD has occurred in the past few years. Systolic dysfunction that is a result of chronic hypoperfusion ("hibernating") and not a result of infarction can now be identified noninvasively by positron emission tomographic scanning, radioisotope imaging, or dobutamine echocardiography. Patients with large areas of myocardial viability may benefit from revascularization. Small, observational studies of patients with hibernating myocardium who are undergoing coronary revascularization have shown functional and perhaps survival benefit, especially when LV function is particularly poor. This is discussed further in Section 5.9.

There are few data regarding optimal choices for women. The higher early surgical mortality needs to be weighed against the lessons derived from the predominantly male subjects (107), and this as well as other subsets will be discussed in Section 5.

It is important to note that the randomized trials did not include patients with an LVEF less than 0.35. Thus, many of the patients operated on today were not well represented in the randomized trials. Results are anticipated from the Surgical Treatment for Ischemic Heart Failure (STICH) study that is a randomized, multicenter trial of medical therapy versus CABG for patients with heart failure, LVEF less than 0.35, and coronary artery disease amenable for CABG.

3.2.2.5. Symptoms/Quality of Life

More attention has been paid to improvement in symptoms and quality-of-life measurements. The findings from randomized trials for these outcomes parallel those of the survival data. Apart from its effect on survival, CABG is potentially indicated for 2 symptom-based indications: to alleviate symptoms of angina pectoris over and above medical therapy and to reduce the incidence of nonfatal outcomes such as MI, CHF, and hospitalization. CABG is considered to improve or to relieve angina pectoris in a much broader group of patients than the subgroups in which it has been found to improve survival. Registry studies have suggested a favorable impact on late MI among highest-risk subsets, such as patients with 3-vessel disease and severe angina pectoris. However, in the pooled data from the randomized trials (85), no overall beneficial impact of CABG on subsequent MI could be demonstrated. This may reflect an early increase in MI perioperatively in patients undergoing CABG surgery balanced by fewer MIs in the long term.

At 5 years, patients treated surgically used less antianginal medicines, with 63% of patients completely symptom-free compared with 38% of medically assigned patients (96). At 10 years, however, these differences were no longer significant. Patients treated surgically and medically used similar amounts of long-acting nitrates and beta-blockers, with 47% of surgical patients asymptomatic compared with 42% of

medical patients. Recreational status, employment, frequency of CHF, use of other medicines, and hospitalization frequency were also similar between the groups (108-115).

At 10 years, the frequency of angina and other quality-of-life measurements were similar between surgically and medically treated groups. Those who have multivessel disease and who receive complete revascularization are less symptomatic, and symptom benefit is most apparent in patients with severe angina and LV dysfunction (EF less than 0.35) (108,110-116). Perhaps because of the symptomatic relief associated with surgical revascularization, the "crossover" from medical treatment to surgery may be of greater significance in improving quality of life. Medically assigned patients who had persistent angina despite medical therapy were able to undergo surgical revascularization and thus obtain relief of symptoms.

3.2.2.6. Loss of Benefit of Surgery

The meta-analysis based on individual patient data from all of the available randomized trials indicates a gradually increasing reduction in mortality over the first 5 to 7 years when coronary surgery is compared with medical therapy. After this period, at about the 10- to 12-year follow-up, there is a tendency of the survival curves to converge. This diminished continued benefit has been shown in the individual studies as well and is likely due to a combination of factors. First, it is inevitable in studies with long-term follow-up that survival curves of various treatment groups will eventually merge. This result has to do with the reduced life expectancy of patients with coronary disease, regardless of treatment.

Second, there is an increased event rate in late follow-up of surgically assigned patients because of the progression of native and graft disease, with a disproportionate increase in late surgical mortality. Finally, crossover to surgery of medically assigned patients is important. Thus, high-risk, medically assigned patients may gain the "benefit" of surgery even when assigned to medical therapy. The crossover rate at 10 years is between 37% and 50%, and this may contribute to the better survival and improved quality of life in such "medically assigned" patients.

3.2.2.7. Summary

CABG improves long-term survival in a broad spectrum of patients at moderate to high risk with medical therapy. Although a relative risk reduction of around 40% can be expected overall in comparison with medical therapy, absolute benefits are proportional to the expected risk with medical therapy. As such, absolute benefit is greatest among those at highest risk with medical therapy (5-year mortality greater than 20%). Clinical and angiographic markers of risk, including severity of CAD, LV dysfunction, and myocardial ischemia, can identify patients in various risk strata.

3.3. Comparison With Percutaneous Techniques

Although PTCA was initially used only for the treatment of single-vessel CAD, advances in technique, equipment, and experience have resulted in its expanded use for patients with multivessel disease. In general, PTCA is less invasive and requires a shorter hospitalization and recovery time than does bypass surgery. However, the disadvantages of PTCA as initial therapy for coronary disease include restenosis of treated lesions and, compared with CABG, a lesser ability to revascularize all lesions in patients with multivessel disease. Clinical trials comparing PTCA and CABG have further defined the relative advantages and disadvantages of these treatments.

3.3.1. Overview of Randomized Trials

Nine randomized, clinical trials comparing PTCA and CABG have been published (Table 11). Before discussing the results of these trials, it is important to consider what we can expect to learn from them. A comparative trial must be large enough to have sufficient statistical power to detect a difference in survival, the usual primary end point. If no difference is observed between CABG and PTCA, it can be concluded that the treatments are equivalent only if trials are large enough to reliably detect or exclude relative differences in mortality of around 20% and include a large number of patients in whom CABG has been shown to improve prognosis. Because 600 deaths would be needed in the "control" group to exclude a relative risk difference of 20% with 90% power, trials with 4000 moderate- to high-risk patients per treatment arm would be needed. However, if a 30% risk difference is considered the smallest clinically important difference, trials of about 2000 patients in each group are required. Unfortunately, all of these trials excluded patients in whom survival had already been shown to be better with CABG when compared with medical therapy. Second, follow-up must be long enough (generally 4 to 5 years) to detect a survival advantage with either approach. Third, to reliably compare the 2 treatments, there must be a high rate of compliance with the original treatment allocation; if a substantial proportion of patients "cross over" (30% to 40% by 5 years), the ability to detect differences in survival decreases markedly. Finally, the patients enrolled in the trial must be similar to those not enrolled to allow generalization of the findings. All of the randomized trials fall short of 1 or more of these criteria. However, the largest of the 9 randomized trials, BARI, comes closest to fulfilling these criteria and will be discussed in detail (117).

In this trial, 1829 patients with multivessel disease were randomized at 18 centers to PTCA or CABG. The primary end point was all-cause mortality at 5 years, and predefined subgroup analyses were performed for the severity of angina, the number of diseased vessels, LV function, and lesion complexity. In addition, a separate analysis of diabetic patients was added partway through the trial. Baseline characteristics of the BARI study population included a mean age of 61 years, mean LVEF of 0.57, a 41% prevalence of 3-vessel disease, and 26% women; there were no significant differences between treatment groups. Revascularization was accomplished by PTCA in a mean of 2.4 lesions per patient, with a success rate of 88% for at least 1 lesion, and by CABG with a mean of 2.8 grafts per patient (82% with an IMA). Stents were not routinely employed (117). The average postprocedure length of stay was shorter with PTCA (3 versus 7 days). The rate of in-hospital Q-wave MI was higher for CABG than for PTCA (4.6% versus 2.1%, P less than 0.05), and 6.3% of PTCA patients required urgent CABG. At a mean follow-up of 5.4 years, there was no statistically significant difference in long-term survival or freedom from MI, but patients initially randomized to PTCA had more hospitalizations and required more repeat revascularization procedures (Table 11). Thirty-one percent of patients initially assigned to PTCA underwent CABG during the trial (117). Compared with the other randomized comparisons, overall mortality in BARI was higher owing to the inclusion of older patients, more women, and more patients with multivessel disease and other comorbidities. This difference underscores the importance of comparing the methodology of these trials before discussing their conclusions.

The most important limitation of all of the randomized trials relates to the ability to generalize the conclusions. The findings are not applicable to all patients with multivessel coronary disease for 2 reasons. First, only around 5% of screened patients with multivessel disease were enrolled in the trials (118,119). In the BARI trial, more than 25 000 patients with multivessel coronary disease by diagnostic angiography were screened for eligibility. About 50% of these patients were ineligible because of left main disease, insufficient symptoms, or other reasons. One third of the remaining patients (4110) had multivessel disease suitable for both PTCA and CABG, and only half of these (7% of those screened) were enrolled in the randomized trial (120). Second, examination of the Emory Angioplasty versus Surgery Trial (EAST) registry suggests that physician judgment may be an important determinant of outcome that is eliminated by a randomized design. In this registry of 450 eligible patients who refused randomization, survival was slightly better than in the 392 randomized patients despite similar baseline features (121). This may reflect physician judgment, as CABG was utilized more often in patients with 3-vessel disease and PTCA more often in patients with 2-vessel disease (121).

The age range (mean age varied from 56 to 61 years) and sex distribution (around 20% female) were similar in most trials, although the Medicine, Angioplasty, or Surgery Study (MASS) trial had 42% women (122). All of the randomized trials excluded patients with low EFs and those for whom CABG was known to provide a survival advantage. Six trials included only patients with multivessel disease and 2, only single-vessel disease (MASS, Lausanne); the Randomized Intervention Treatment of Angina (RITA) trial included both (Table 11). Several trials were conducted in

single centers, whereas RITA, the German Angioplasty Bypass-surgery Investigation (GABI), the Coronary Angioplasty versus Bypass Revascularization Investigation (CABRI), and BARI were multicenter. The CABRI and EAST trials permitted incomplete revascularization, whereas the others had a goal of complete revascularization. CABRI and RITA included vessels with total occlusion, accounting for the lower success rate of PTCA; the success rate for these vessels in RITA was only 48%. Asymptomatic patients were excluded from GABI, and the extent of coronary disease also varied widely. Three-vessel disease was present in only 12% and 18% of RITA and GABI subjects, respectively, and present in greater than 40% of BARI and Estudio Randomizado Argentino de Angioplastia vs Cirugia (ERACI) patients. The incidence of diabetes mellitus varied from 10% to 12% (Toulouse, Goy, ERACI, GABI, and CABRI) to greater than 20% (EAST and BARI).

Finally, the trials used different primary end points and follow-up periods. Neither CABG nor PTCA has been shown to reduce the risk of subsequent nonfatal MI, and therefore inclusion of such an end point would dilute relative differences and decrease the likelihood of detecting differences. End points included survival (BARI), freedom from angina (GABI and Toulouse), freedom from death and MI (RITA), and other combinations including symptoms, stress thallium defects, and repeated revascularization (Table 11). Most required Q waves and a clinical event to define an MI, but EAST included "silent" MIs as well. Follow-up ranged from 1 to 5 years, and only MASS required angiography in all patients (122). Overall, all of the trials except BARI were underpowered and lacked sufficient follow-up.

3.3.2. Results of Randomized Trials

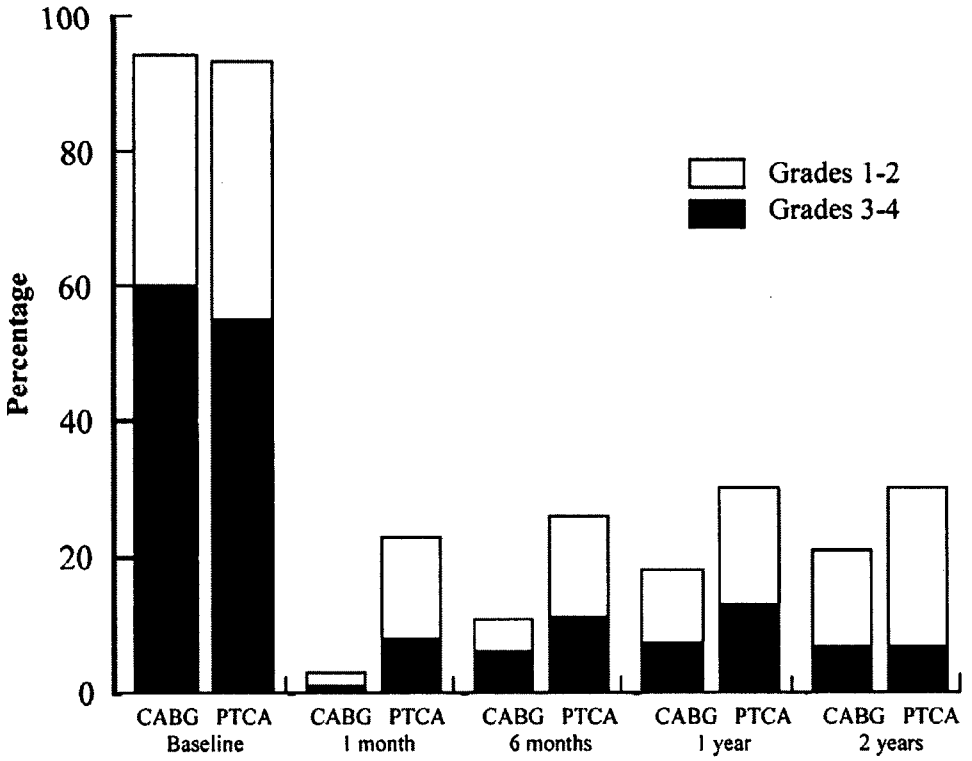
3.3.2.1. Acute Outcome

Despite the differences in design and follow-up, the results of randomized trials comparing PTCA and CABG have been similar. Procedural complications including death (1% to 2%) and Q-wave MI (up to 10%) were low for both procedures but tended to be higher with CABG (Table 11). A statistically significant increase in MI rate was present only in GABI and EAST and in 2 meta-analyses including many of the trials (118,123). For patients initially randomized to PTCA, CABG was needed during the initial hospitalization for 6% (range 1.5% to 10%) and was performed in close to 20% by 1 year (123).

The cost and length of stay were lower for PTCA than for CABG. In BARI, the cost of PTCA was 50% of that for CABG, but over time this was nearly equal (124,125). The lengths of stay in RITA were 4 and 12 days for PTCA and CABG, respectively (126). Patients having PTCA returned to work sooner and were able to exercise more at 1 month (127). The extent of revascularization achieved with CABG was higher than with PTCA (117,119). In the EAST trial, the percentage of revascularizable segments successfully treated was 99% for CABG versus 75% for PTCA (119). When the comparison was limited to severe and physiologically important lesions, the extent of early revascularization was similar, although this analysis includes the patients who crossed over from PTCA to CABG (119,128).

3.3.2.2. Long-Term Outcome

There was no significant difference in survival in 8 of the 9 randomized trials that compared PTCA and CABG at follow-up periods ranging from 1 to 8 years (Table 11). BARI was the largest trial with the longest follow-up. The combined end point of cardiac mortality and MI was similar at 5 years with both treatments (129). An update of the BARI trial results with a mean follow-up of 7.8 years has now demonstrated a survival advantage in the overall study (84.4% with CABG versus 80.9% with PTCA, P equals 0.043), due to a marked survival benefit in the study subjects with diabetes who were treated surgically (76.4% versus 55.7% with PTCA, P equals 0.0011) (130). Longer follow-up analyses of EAST and ERACI have not demonstrated any differences in mortality (131,132).



None of the trials or meta-analyses were able to demonstrate a difference in Q-wave MI or the combined end point of death and MI (Table 11) (118,123). Most trials found that CABG resulted in greater freedom from angina, and the difference from PTCA was statistically significant in EAST, Toulouse, RITA (Figure 5), and CABRI. Exercise time at 2.5 years was assessed in RITA and favored patients initially treated by PTCA (191 versus 171 minutes) (126). Large thallium defects (assessed in EAST) were slightly more common in PTCA patients at 3 years (119). The relative risk for angina with PTCA tended to be higher early but decreased with longer follow-up (123) (Figure 5).

The most striking difference between the treatments was in the need for subsequent procedures. The rate was 4- to 10-fold higher for PTCA in every trial (Table 11). Three trials (Lausanne, MASS, and ERACI) that included repeated revascularization as part of the primary, composite end point demonstrated a statistically significant reduction in events with CABG (122,133,134). Eight percent of CABG patients required additional revascularization within 5 years in BARI, compared with 54% of PTCA patients (117). Additional procedures were needed earlier in PTCA patients and included PTCA only (23.2%), CABG only (20.5%), or both (10.8%) (117).

Several studies have compared quality of life and cost with various revascularization strategies (124,127,135,136). In RITA, physical activity and employment were similar for both procedures after 3 years (127). A BARI substudy including 52% of enrollees found that functional status assessed by the Duke Activity Index improved more with CABG early on but was equivalent by 5 years (124). Emotional health and employment were also similar in this study and others (124,127,135). The early cost benefit of PTCA decreased during follow-up owing to the more frequent need for repeated procedures and hospitalization such that, over the long term, PTCA approached the cost of

CABG (123,124,135,136). There appeared to be a greater cost benefit to PTCA in patients with 2-vessel disease (124). In BARI, it was estimated that the slight survival advantage of CABG would cost $26 117/year of added life (124).

Comparison with stents

Since the previous update of these guidelines, several trials comparing stents with CABG in patients with multivessel disease have been initiated. The Arterial Revascularization Therapies Study Group (ARTS) trial enrolled 1205 patients with multivessel coronary disease in whom a cardiac surgeon and interventional cardiologist agreed that they could achieve a similar extent of revascularization. In this randomized comparison, there was no difference at 1 year in the combined rate of death, MI, and stroke between the 2 revascularization strategies (137). However, repeat revascularization rates were higher with stenting (16.8% versus 3.5% with surgery), with a net cost savings of $2973 per patient favoring the stent approach. In diabetic patients (n equals 198), the difference in repeat revascularization rates was even more disparate (22.3% with stents versus 3.1% with CABG), although overall event-free survival was similar (138) (Table 11).

Similar results were reported by the Stent or Surgery (SoS) trial investigators. The trial randomized 988 patients with multivessel disease (57% 2-vessel; 42% 3-vessel) to revascularization with PCI (78% received stents) or CABG (81% with pedicled left IMA graft). The primary end point of repeat revascularization occurred in 21% of PCI patients versus 6% of CABG patients at a median follow-up of 2 years (hazard ratio equals 3.85, P less than 0.0001). Freedom from angina was also better with surgery (79% versus 66%). Mortality was higher in the PCI group, but this was influenced by a particularly low surgical mortality and a high rate of noncardiovascular deaths in the PCI group (139).

Downloaded from circ.ahajournals.org by on August 4, 2008

In the Angina with Extremely Serious Operative Mortality Evaluation (AWESOME) study, 454 patients at 16 VA hospitals with high-risk features for adverse outcome with surgery were randomized to either CABG or PCI. High-risk characteristics included prior open-heart surgery, age greater than 70 years, ejection fraction less than 0.35, MI within 7 days, and IABP. Stents were used in 54% of PCI patients. Survival was similar (79% with CABG and 80% with PCI) at 36 months (140). Finally, in the Stenting versus Internal Mammary Artery (SIMA) trial, 121 patients with isolated proximal LAD coronary artery disease were randomly treated with stenting or CABG (using the IMA). At 2.4 years of follow-up, there were no differences in the rates of death, MI, functional class, medications, or change in quality of life. Repeat revascularization was required more often (31% versus 7%) in the stent group (141). Overall, 6 trials have now been published comparing CABG with PCI using stents in single or multivessel disease. Compared to the earlier trials with balloon angioplasty, stent usage and left IMA revascularization rates have increased. The results in terms of death, MI, and stroke are similar in the more recent trials; however, the disparity in the need for repeat revascularization, which favors surgery, has narrowed (Table 11).

3.3.2.3. Special Subsets

The BARI trial prespecified 4 subsets for analysis. The primary end point of survival did not differ in these subgroups based on severity of angina, extent of disease, LV function, and lesion complexity (117). However, 3-year cardiac mortality was higher with PTCA in several high-risk groups (in unstable angina and non–ST-elevation MI (NSTEMI), PTCA 8.8% versus CABG 4.9%; in CHF, PTCA 27.7% versus 16.4% with CABG) (129). The ERACI trial included a high proportion (83%) of patients with unstable angina, and there was no difference in survival at 1 year (133).

Data from fibrinolytic trials suggesting an adverse effect of diabetes mellitus on PTCA outcome prompted the addition of treated diabetes mellitus as a subgroup for analysis partway through the BARI trial (117,142). This subgroup of 353 patients (19% of total) was more likely to be women or members of minorities and belong to a lower socioeconomic class. They also had more severe heart disease and comorbidities, but their in-hospital complications were similar to those in patients without diabetes and were also higher for CABG than for PTCA (143).

All-cause mortality and cardiac mortality were both higher in patients with diabetes treated with PTCA (34.7% versus 19.1% and 20.6% versus 5.8%, respectively) (Figure 6) (142). This benefit of CABG was confined to patients receiving IMA grafts, which may reflect a selection bias or the low numbers of patients not receiving IMA grafts. A similar result with regard to patients with diabetes was found in a post hoc analysis of 122 patients with diabetes in CABRI (143), but no difference was found for patients with diabetes in EAST (119).

A separate meta-analysis of the randomized trials for single-vessel disease has also been performed (123). As

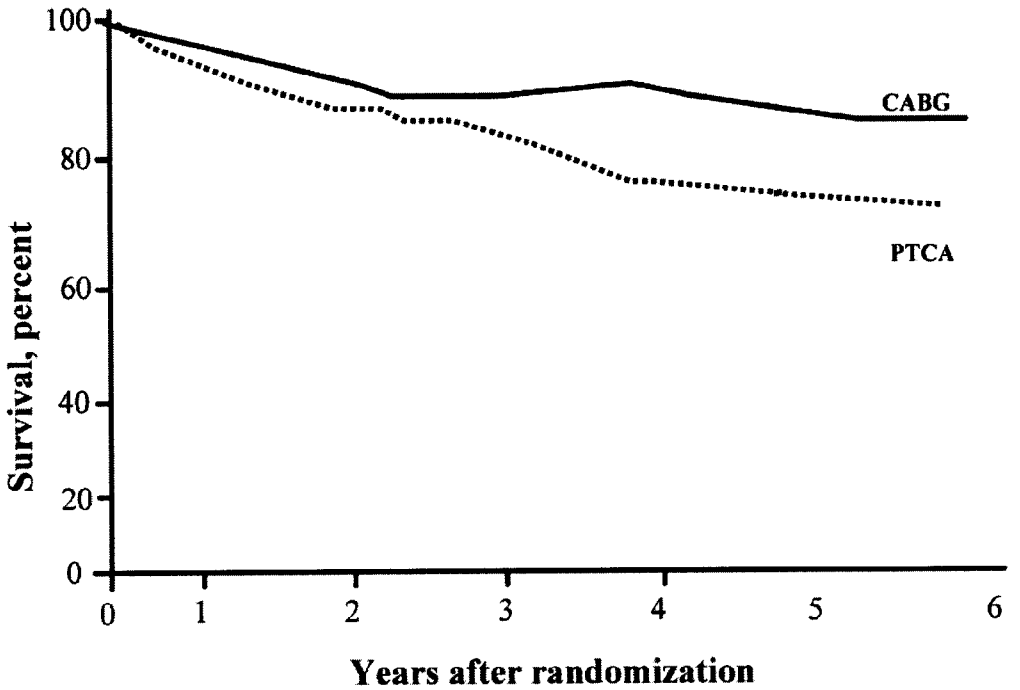

Figure 6. Improved survival with coronary artery bypass graft surgery (CABG) versus percutaneous transluminal coronary angioplasty (PTCA) in patients with diabetes mellitus. Results from the Bypass Angioplasty Revascularization Investigation (BARI) showing that patients with multivessel coronary disease who were being treated for diabetes at baseline had a significantly better survival after coronary revascularization with CABG (solid curve) than with PTCA (dashed curve) ($P = 0.003$). Modified with permission from Circulation. 1997;96:1761-9 (142).

Downloaded from circ.ahajournals.org by on August 4, 2008

expected, the overall risk for events was less than in patients with multivessel disease. Although the risk of death and MI was lower with CABG, this finding should be interpreted with caution, since no such difference was found for multivessel disease. The need for late CABG was lower in patients with single-vessel disease, and there was less difference in angina frequency (123).

3.3.2.4. Results From Nonrandomized Trials and Registries

Much of the debate relating to the finding for a survival advantage of CABG in treated patients with diabetes is based on the results of nonrandomized trials and registries. Treated patients with diabetes in the BARI registry who refused randomization and selected their form of revascularization did not fare worse with PTCA (144). In a retrospective cohort study comparing PTCA and CABG for patients with diabetes with multivessel disease and similar age, sex, EF, and severity of angina, there was also no difference in survival after 6 years (145). However, in one comparison of CABG and PTCA in a nonrandomized, observational database, patients with diabetes requiring insulin had a lower long-term survival after treatment with multivessel PTCA (146). Limitations of this conclusion include the unknown adequacy of glucose control and the absence of a survival advantage for CABG when patients in the randomized trials are pooled and in other, nonrandomized registries (147).

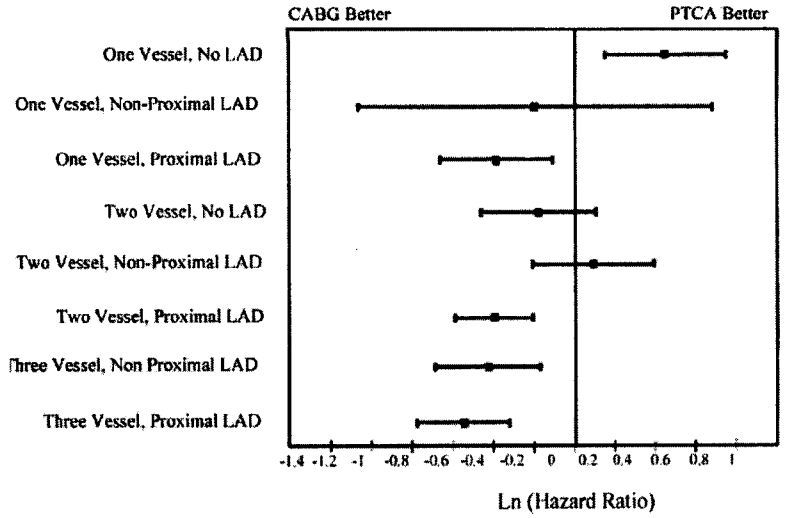
The majority of patients in the randomized trials had angina. A small trial that demonstrated improved outcomes with revascularization compared with medical therapy in patients with asymptomatic ischemia also examined the relative benefits of the type of revascularization (148). In this nonrandomized trial, CABG provided superior relief of exercise-induced as well as ambulatory ischemia compared with PTCA (149).

A more compelling report was published by Hannan et al (150), which described a 3-year survival analysis of the 30000 patients enrolled in the New York State PTCA registry compared with that of 30000 patients in the CABG registry from 1993 to 1995. As opposed to the randomized trials, this large experience showed a survival benefit for patients receiving CABG when proximal LAD stenosis was greater than 70%, regardless of whether 1-, 2-, or 3-vessel disease was present (Figure 7) (Table 12) (150). Patients with 3-vessel disease not involving the proximal LAD also fared better with CABG than with PTCA. Patients with 1-vessel disease without severe proximal LAD stenosis had better survival with PTCA. Several potential limitations of this experience deserve comment. Unmeasured differences in patient severity not accounted for in the risk-adjustment method could have affected the conclusions. Similarly, physicians' choice of treatment may have been based on unmeasured patient factors. Finally, coronary stents were utilized in just 11.8% of the PCI patients.

3.3.2.5. Conclusions

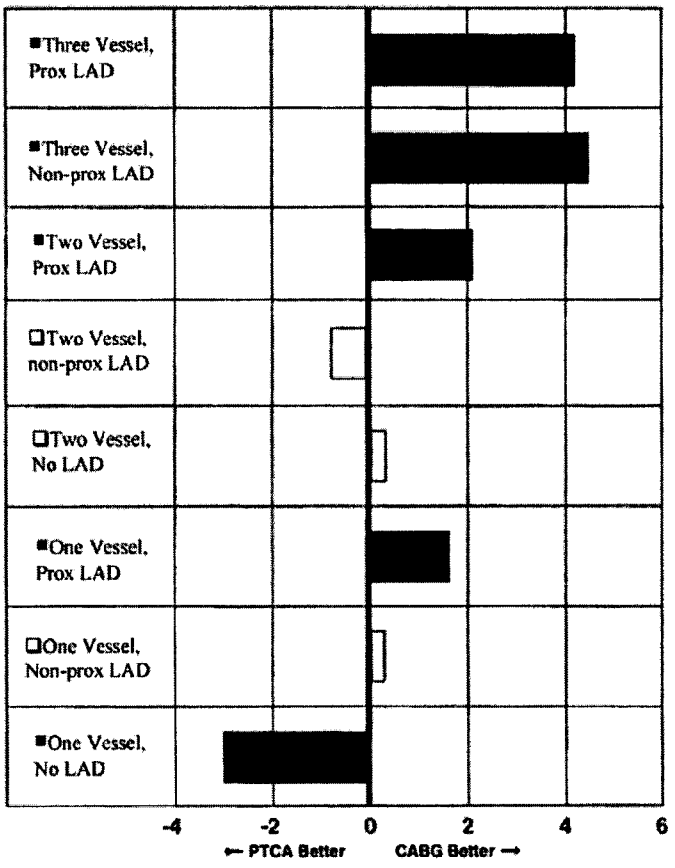
For patients included in the randomized trials, CABG provided better relief of angina with a lower need for subsequent procedures. Initial complications are higher with CABG, as are the cost and length of hospitalization. Patients may return to work sooner after PCI but are subsequently hospitalized more often, thus generating similar overall long-term costs. Randomized trials do not show any difference in late death or rate of MI, except in patients with treated diabetes mellitus, for whom CABG may be superior. Conversely, data from large registries, particularly those of New York State, suggest that patients with severe, proximal LAD stenosis and/or 3-vessel disease may achieve improved survival with CABG. Patients with 1-vessel disease not involving severe proximal LAD disease may do better with PCI.

Several important caveats and limitations to these conclusions must be discussed. Since completion of the trials, the influence of new technology, particularly on PCI, has been considerable. Intracoronary stents are now used in 70% or more of PCIs and have reduced the need for both urgent CABG and subsequent procedures by as much as 50% (151). Continuing advances in PCI and stent designs, the use of brachytherapy (local radiation), and drug-eluting stents have further reduced the need for repeat procedures. Medical management of atherosclerosis, both before and after revascularization, has continued to evolve, with greater use of beta-blockers and inhibitors of the renin-angiotensin-aldosterone system after MI and the introduction of statins and other lipid-lowering agents. The ability to select patients for revascularization procedures by using a methodology that can separate scarred from viable myocardial segments will undoubtedly alter the outcomes from these procedures. Other changes in patient management that may influence these conclusions include the use of platelet glycoprotein IIb/IIIa inhibitors and/or direct thrombin inhibitors during percutaneous interventions, the more frequent use of IMA grafts, and the emergence of less-invasive surgical approaches.



It is likely that during the progress of their disease, many patients will benefit from a combined application of percutaneous and surgical techniques, taking advantage of the low morbidity of percutaneous methods and the established long-term benefit of surgical revascularization with arterial conduits.

4. MANAGEMENT STRATEGIES



4.1. Reduction of Perioperative Mortality and Morbidity

One of every $10 spent on surgical treatment of coronary disease is related to a complication, a sum of 1 billion dollars annually in the United States (152). Careful evaluation of patient characteristics should lead to proper risk stratification and the identification of areas for risk neutralization. Some risk factors that at first appear immutable may in fact be markers or surrogates for conditions that can be modified. The incremental incorporation of new advances can lead to coronary bypass results that are superior to those of the past. The following discussion formalizes this mind-set of risk

neutralization to maximize the margin of safety for coronary bypass.

4.1.1. Reducing the Risk of Brain Dysfunction After CABG

One of the most devastating complications of coronary bypass surgery is perioperative stroke. In addition to patient morbidity and mortality, there are indirect costs through lost productivity; the direct economic cost of a stroke ranges from $90 000 to $228 000 over a patient's life span (153-155). Postoperative stroke is the second most common cause of operative mortality (after low cardiac output state) (156). The incidence of stroke after coronary operation is related to increased age (53,157-159) (Figure 8A), which parallels the accelerated involvement of the aorta and great vessels with atherosclerotic plaque (156) (Figure 8B). Age per se is less important than atherosclerosis, which plays a role in at least two thirds of adverse events after coronary bypass.

As discussed in Sections 4.1.1.1 and 4.1.1.2, post-CABG neurological events can be classified into type 1 injuries, which are predominantly focal stroke, transient ischemic attack, and fatal cerebral injuries, and type 2 events, which reflect a more global/diffuse injury, with disorientation or immediate (and usually reversible) intellectual decline.

4.1.1.1. Type 1 Neurological Injury

Type 1 injury occurs in 3.1% of patients, is responsible for a 21% post–coronary bypass mortality rate, 11 days in the intensive care unit, 25 days in hospital, at least an additional $10 266 in hospital boarding charges, and a cost of 5 to 10 times the in-hospital charge for rehabilitative and outpatient support (51,148).

4.1.1.1.1. Aortic Atherosclerosis and Macroembolic Stroke. The surgeon's identification of an atherosclerotic ascending aorta is the single most significant marker for an adverse cerebral outcome after coronary bypass operations (OR 4.5, *P* less than 0.05) (48), reflecting the role of aortic atheroembolism as the cause of ischemic stroke (161-165). Since the early days of the operation,

Downloaded from circ.ahajournals.org by on August 4, 2008

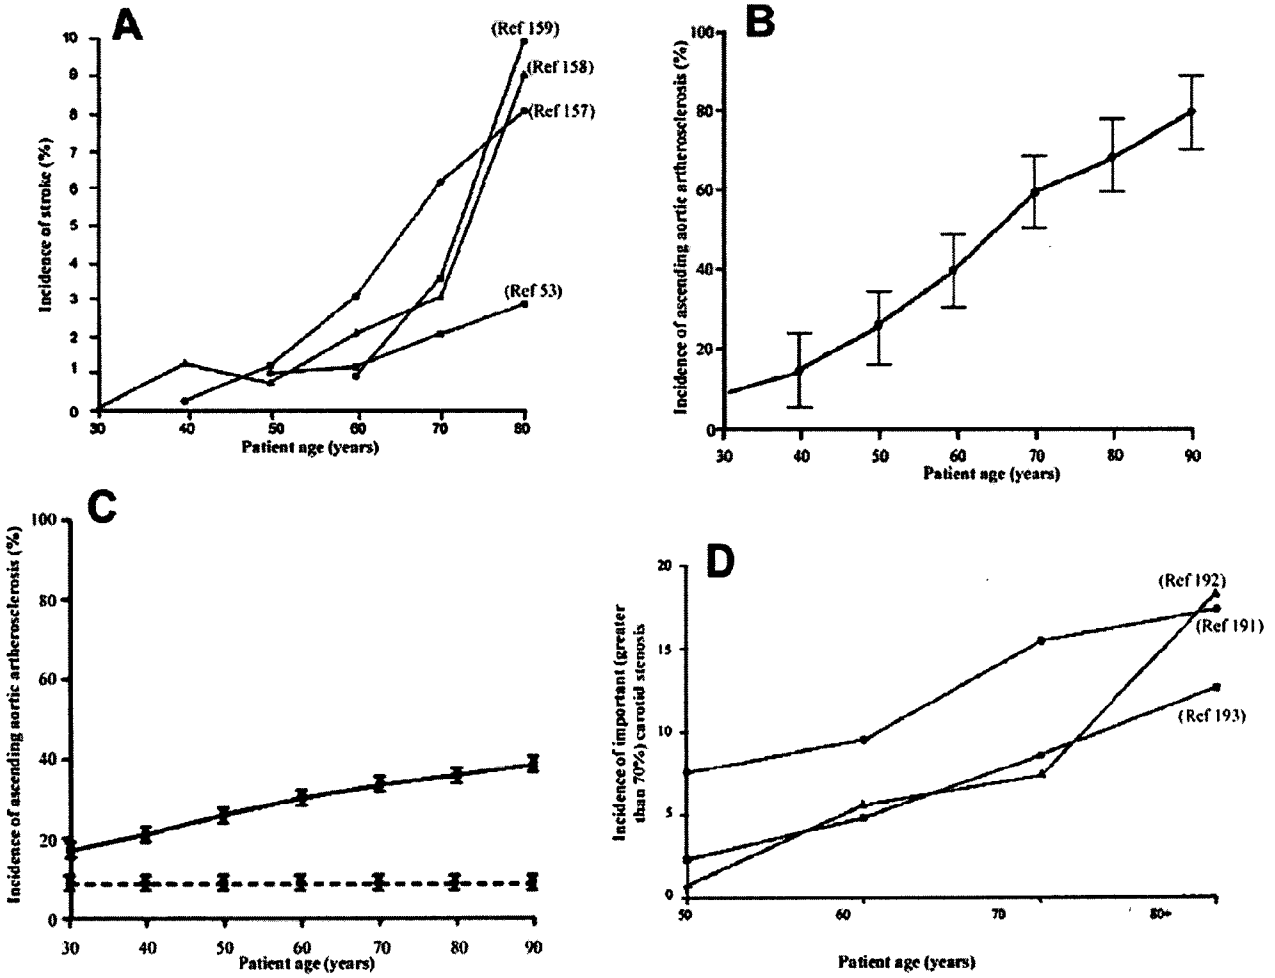

Figure 8. A: Incidence of permanent, focal, central nervous system injury after coronary bypass is strongly correlated with increasing age. **B:** Ascending aortic atherosclerosis is a powerful marker of increased risk for perioperative stroke in the coronary bypass population and increases directly with age. **C:** Strong correlation between perioperative atheroembolism and the degree of atherosclerotic involvement of the ascending aorta. The solid line represents severe atherosclerotic involvement the interrupted line, lesser involvement. **D:** Extracranial cerebrovascular disease is a significant contributor to stroke after coronary bypass and is strongly correlated with age, suggesting a population for aggressive preoperative screening. Panels B and C are reprinted with permission from Elsevier Science, Inc. (Blauth et al. J Thorac Cardiovasc Surg.1992;103:1104-11) (169).

atheroemboli and calcific debris have been detected in the cerebral circulation in patients dying after coronary bypass surgery (166). Since the average age of patients having coronary bypass is increasing, perioperative atheroembolism from aortic arch plaque is also increasing and is likely responsible for 1 in 3 strokes after coronary bypass (167). This risk is particularly increased in patients beyond 75 to 80 years old (49) (Figures 8B and 8C). Most perioperative cerebral atheroembolization likely arises intraoperatively from manipulation of the ascending or transverse aorta during cannulation, clamping, or placement of proximal anastomoses or from the shear effect of the flow from the aortic cannula (168,169,170). Preoperative, noninvasive testing for detection of the high-risk patient has limited sensitivity. Computed tomography identifies most severely involved aortas but underestimates mild to moderate involvement compared with echocardiography (163,171). TEE is useful for examination of the aorta, and although evaluation of the ascending aorta was somewhat limited by the intervening trachea (159) with earlier monoplane techniques, multiplane TEE technology allows good visualization of the aorta. However, the intraoperative assessment of ascending aortic atheroma by epiaortic imaging (in which the imaging probe is placed directly on the aorta) is superior to both TEE and direct palpation (160).

TEE identification of mobile arch atheroma in patients undergoing CABG was associated with a 33% stroke rate versus 2.7% in patients with nonmobile plaque (P equals

Downloaded from circ.ahajournals.org by on August 4, 2008

0.01) (172). Intraoperative palpation is notorious for its underestimation of the high-risk aorta (160). Palpation detected only one third of atherosclerotic lesions identified by epivascular echocardiography (171). The aortic pattern with the highest risk is the protruding or mobile aortic arch plaque, and this eludes intraoperative palpation in 80% of cases (173). Intraoperative epivascular ultrasound represents an important advance and is now used in many centers for intraoperative diagnosis and stroke risk reduction (171,174). The technique is highly sensitive and specific for identification of the high-risk aorta.

An aggressive approach to managing patients with severely atherosclerotic ascending aortas identified by intraoperative epiaortic ultrasound imaging appears to reduce the risk of postoperative stroke (53,175). Twelve hundred of 1334 consecutive open heart surgery patients (88% with coronary disease) underwent screening with intraoperative epivascular ultrasound. These findings led to a change in intraoperative technique in 19.3% of patients. In patients with 3 mm or less of aortic wall thickening, standard techniques were used. When the aorta demonstrated a greater than 3-mm thickening, the cannulation, clamp, or proximal sites were changed, or a no-clamp fibrillatory arrest strategy (176) was used. For high-risk patients with multiple or circumferentially involved areas or those with extensive mid-ascending aortic involvement, the ascending aorta was replaced under hypothermic circulatory arrest. The 27 high-risk patients had no strokes and a mortality rate of just 3%. Among patients with a moderately to severely involved aorta treated with the less-radical approaches, the incidence of stroke was 6.3%. When epivascular ultrasound showed no or mild atherosclerotic disease, the stroke incidence was low, 1.1% (53,176).

In a smaller study of epivascular echo-directed management, 195 consecutive coronary patients undergoing CABG were compared with a control group of the previous consecutive 165 patients for whom only the surgeon's palpation was used to evaluate the aorta. Ten percent of the epivascular group had the intraoperative technique modified versus 3% of the control group. The most common change in operative approach was use of a no-clamp, cold fibrillatory arrest technique. Three percent of the control group had strokes compared with none of the epivascular echo-managed group (P less than 0.02) (51).

With a no-clamp technique, the surgeon may completely revascularize the heart with standard in situ IMA and aortically based SVGs, typically constructing a single, proximal anastomosis during a brief period of total circulatory arrest on a safe area of the aorta. Alternatively, the surgeon may use an all-in situ arterial revascularization approach, or SVGs may be grafted onto the in situ IMA by using an end vein to side artery anastomosis (167,177).

Preoperative risk assessment may identify a small population of patients with such extensive aortic atherosclerosis and poor outlook that the benefit from coronary bypass would appear to be very small. This population is difficult to define, but a starting point may include patients with aortic plaques 4 mm or more or with certain morphologies that are associated with only a 20% chance at 4 years of freedom from peripheral embolism, MI, recurrent stroke, or death (165). This risk, along with an extremely high perioperative risk, would argue for nonoperative treatment. However, if the cardiac risk of medical therapy is high (5-year mortality greater than 20%), alternative forms of revascularization should be considered. These include off-pump bypass surgery; minimally invasive direct CABG (MID-CAB) without CPB, with or without concomitant PCI; and exclusive percutaneous revascularization. These techniques may provide the benefit of revascularization in such high-risk patients while minimizing the perioperative risk of stroke. There are few randomized trials that examine the specific impact of CPB on stroke incidence, but 1 randomized study showed a comparable stroke rate in patients without CPB (off-pump) versus those on-pump (56). These patients were not stratified according to high-risk aortic disease, so the relative value of off-pump surgery in such patients remains unknown.

4.1.1.1.2. Atrial Fibrillation and Postoperative Stroke.

Class IIa

In post-CABG atrial fibrillation that is recurrent or persists more than 24 hours, warfarin anticoagulation for 4 weeks is probably indicated. *(Level of Evidence: C)*

Chronic atrial fibrillation is a hazard for perioperative stroke as a result of cardiac thromboembolism. Intraoperative surgical manipulation or spontaneous resumption of sinus rhythm early in the postoperative period may be associated with embolism of a left atrial clot. One potential approach to reduce atrial fibrillation-associated embolism is the performance of preoperative TEE. Absence of a left atrial clot would suggest that the operation may proceed with acceptable risk. If a left atrial clot is identified, 3 to 4 weeks of anticoagulation, restudy, and then subsequent operation is a rational approach if the clinical situation allows this. Unfortunately, few clinical trial data are available to assist physicians in the best management for this situation.

New-onset postoperative atrial fibrillation occurs in 30% of patients undergoing CABG (178-180), with the peak incidence on the second to third postoperative day (181). It is associated with a 2- to 3-fold increase in postoperative risk for stroke (182,183). Patients at risk for postoperative atrial fibrillation have been identified and include those with COPD, proximal right CAD, prolonged cross-clamp time, atrial ischemia, advanced age, and withdrawal of beta-blockers. Identifying at-risk patients and directing treatment to these patients (see Section 4.1.5) appears to be effective in reducing the incidence of post-CABG atrial fibrillation and thus the morbid complication of postoperative strokes associated with this arrhythmia. Minimally invasive and off-

Downloaded from circ.ahajournals.org by on August 4, 2008

pump beating-heart procedures may also reduce the incidence of postoperative atrial fibrillation (184,185).

The role of anticoagulation in patients who develop post-CABG atrial fibrillation is unclear. In general, an aggressive anticoagulation and cardioversion philosophy may reduce the neurological complications associated with this arrhythmia. However, the risks of pericardial bleeding and tamponade have to be weighed with early use of full anticoagulation. Early (within 24 hours of onset of atrial fibrillation) attempts at cardioversion can probably be safely performed without anticoagulation. However, if the arrhythmia persists beyond this time, it may be advisable to use intravenous heparin while cardioversion is attempted. In certain patients, TEE can be used to exclude left atrial appendage thrombus and help to direct cardioversion. In such patients, it is generally recommended that anticoagulation be used after the cardioversion (186). If the atrial fibrillation persists, anticoagulation with warfarin on an outpatient basis is probably indicated when the benefit of anticoagulation in selected patients (186a-c) exceeds the risk of bleeding in the postoperative interval in the judgment of the surgical team. Further attempts at cardioversion are determined by the individual patient profile (187).

4.1.1.1.3. Recent Anterior MI, LV Mural Thrombus, and Stroke Risk.

Class IIa

Long-term (3 to 6 months) anticoagulation is probably indicated for the patient with recent anteroapical infarct and persistent wall-motion abnormality after CABG. *(Level of Evidence: C)*

Class IIb

In patients having a recent anterior MI, preoperative screening with echocardiography may be considered to detect LV thrombus, because the technical approach and timing of surgery may be altered. *(Level of Evidence: C)*

The patient with a recent anterior MI and residual wall-motion abnormality is at increased risk for development of an LV mural thrombus and its potential for embolization. Keren et al (188) identified LV thrombus in 38 of 124 anterior-infarct patients (31%) and in none of 74 patients with inferior infarcts (*P* less than 0.001). Early fibrinolytic therapy was not uniformly protective against LV thrombus, and 30% occurred after discharge. Such patients are at risk for systemic embolization of the LV clot, and the risk is highest in the first few weeks after the acute infarct. Preoperative screening with echocardiography may demonstrate the clot and alter the technical approach and perhaps the timing of surgery. Also, long-term (3 to 6 months) anticoagulation is probably recommended for the patient with persistent anterior wall-motion abnormalities after coronary bypass. LV thrombus may recur in patients receiving short-term (2 months or less) anticoagulation. Apical akinesis at 10 days after infarction was a strong predictor for subsequent thrombus formation, which conferred an increased risk for subsequent stroke (189).

4.1.1.1.4. Recent Antecedent Cerebrovascular Accident.

A recent, preoperative cerebrovascular accident presents another situation in which delaying the operation may reduce the perioperative neurological risk. Evidence of a hemorrhagic component to the cerebrovascular accident, based on the results of a computed tomography scan, identifies those patients at particular risk for extension of the neurological damage due to heparinization and CPB (189). It is generally believed that a delay of 4 weeks or more is prudent if coronary anatomy and symptoms permit.

4.1.1.1.5. CPB Time and Neurological Risk.

Increased time on CPB is closely correlated with adverse neurological outcome, emphasizing the need for an organized, expeditious operation. On average, patients without postoperative neurological events have shorter pump times than those who develop postoperative stroke and/or type 2 deficits (190).

4.1.1.1.6. Carotid Disease and Neurological Risk Reduction.

Class IIa

1. **Carotid endarterectomy is probably recommended before CABG or concomitant to CABG in patients with a symptomatic carotid stenosis or in asymptomatic patients with unilateral or bilateral internal carotid stenosis of 80% or more. *(Level of Evidence: C)***
2. **Carotid screening is probably indicated in the following subsets: age greater than 65 years, left main coronary stenosis, peripheral vascular disease, history of smoking, history of transient ischemic attack or stroke, or carotid bruit on examination. *(Level of Evidence: C)***

Extracranial carotid disease is significantly associated with a type 1 adverse neurological outcome (*P* equals 0.001) (48). Hemodynamically significant carotid stenoses are associated with as many as 30% of early postoperative coronary bypass strokes (158). Strokes caused by carotid disease are particularly devastating, since they often occur on the second to ninth postoperative day in the midst of an apparently smooth recovery (159). The trend for coronary surgery to be performed in an increasingly elderly population underscores the importance of the issue (Figure 8D) (169,191-193). The prevalence of significant carotid disease in the current cardiac surgery population reflects the diffuse nature of the atherosclerotic process: 17% to 22% of patients have 50% carotid stenosis, and 6% to 12% have 80% carotid stenosis (191,194). Perioperative stroke risk is 2% when carotid stenoses are less than 50%, 10% when stenoses are 50% to 80%, and 11% to 18.8% in patients with stenoses greater

Downloaded from circ.ahajournals.org by on August 4, 2008

than 80% (53,195). Although the patient with untreated, bilateral, high-grade stenoses or an occluded carotid artery and contralateral high-grade stenosis is rare, such patients have a 20% chance of stroke (196,197).

Conversely, the leading cause of short- and long-term risk for patients having surgical treatment of carotid disease is the associated coronary disease (198-201). CABG is the most effective treatment for many of these patients. Provided that the surgical team has acceptable results with endarterectomy, prophylactic carotid endarterectomy is superior to conservative therapy for prevention of stroke in symptomatic or asymptomatic patients with high-grade carotid stenoses (202-204).

With proper teamwork, carotid endarterectomy for high-grade stenosis preceding or coincident with a coronary operation can be associated with a low risk for short- and long-term adverse neurological sequelae (114,196,198,205) (Figure 9). Carotid endarterectomy done before or concomitant with coronary bypass carries a low mortality (3.5%), reduces early postoperative stroke risk to less than 4%, and confers a 10-year rate of freedom from stroke of 88% to 96% (196,205,206). Special interest in this problem among caregivers and careful collaboration between the carotid and coronary surgical teams are keys to success. Stroke and mortality rates after carotid endarterectomy also are inversely related to institutional volume (207,208).

The absence of symptoms referable to carotid disease is not reassuring because a carotid stenosis of 75% in an *asymptomatic* patient is an independent predictor of stroke risk immediately after CABG (OR of 9.87, *P* less than 0.005) (158,159). The presence or absence of a cervical bruit is poorly predictive of a high-grade stenosis even in the setting of known symptomatic carotid disease (sensitivity 63%, specificity 61%) (209).

A prospective examination of preoperative carotid duplex scans in 1087 open-heart surgical patients aged 65 or older defined the markers associated with important (80%) carotid stenosis: female sex, PVD, previous transient ischemic attack or stroke, smoking history, or left main disease (*P* less than 0.05) (191). If all patients with at least 1 of these risk factors were screened, 95% of those with an 80% stenosis would be detected and 91% of those with a 50% stenosis would be detected. Unfortunately, this would lead to screening in 85% of patients aged 65 years or older. This example illustrates the correlation of carotid stenosis with age and suggests that the lower limit of age at which carotid screening will be cost-effective is not yet known. For safety and simplicity, many centers screen all of those aged 65 or older. The strong association between left main disease and carotid stenosis argues that left main patients should be screened at any age. Similarly, those with a previous transient ischemic attack or stroke should receive carotid screening independent of age. Preoperative CNS symptoms suggestive of vertebrobasilar artery insufficiency should lead to evaluation by magnetic resonance angiography to allow informed consideration of management options.

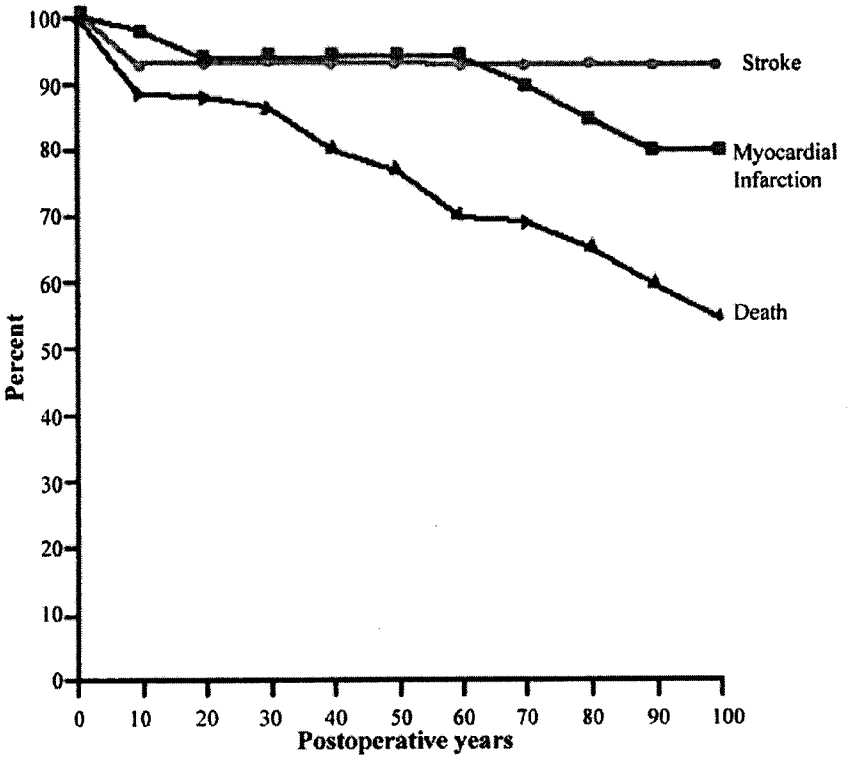

Figure 9. Contemporaneous surgical treatment of carotid and coronary disease is associated with an excellent long-term outcome. The gap shows freedom from stroke, myocardial infraction, and death over time. Reprinted with permission from Akins et al. Ann Thorac Surg. 1995;60:311-7) (205).

Downloaded from circ.ahajournals.org by on August 4, 2008

When surgical treatment of concurrent carotid and coronary disease is planned, the procedures may be done in either a combined (same operative setting, carotid to precede coronary revascularization) or *staged* fashion. The *staged* approach is most commonly used, particularly in patients with noncritical coronary anatomy. Postoperative care is rendered in a telemetry setting, with aggressive monitoring and treatment to prevent postoperative myocardial ischemia. CABG follows in 1 to 5 days with the use of standard techniques. The superiority of the combined versus staged approach has not been established by prospective trials. Thus, current tactics are best left to local team policies and preferences based on careful examination of team outcomes. An individualized, patient-specific, *selective* approach with the decision based on symptoms and the relative severity of extracranial cerebrovascular disease and coronary disease appears prudent and is used in many institutions. The results of these approaches in a collation (198) of 7 published series, each with 100 patients, published from the mid-1980s to the mid-1990s had an overall mortality rate of 4%, with permanent neurological deficit in 3.4% of patients.

Some observational series have suggested that *combined* carotid/coronary operations carry a higher risk for in-hospital stroke and mortality compared with patients in the same institution having a *staged* procedure (210). These studies may be confounded by selection bias toward recommending *combined* operations in patients with more advanced carotid and coronary disease. Contrariwise, a recent, single-center series in which a *combined operation for all patients* with concurrent carotid and coronary disease was used suggested this approach to be safe and to have low overall resource requirements (205). However, another multicenter study suggested a considerably higher risk (191a). Thus, some uncertainty remains, underscoring the need for prospective appropriately-controlled, randomized study of this method (191b,191c).

Stroke risk appears to be increased when the so-called *reverse-staged* procedure is used. In this strategy, the coronary bypass precedes the carotid endarterectomy by 1 day during the same hospitalization. A prospective, randomized trial that evaluated this approach demonstrated an increased risk of stroke (14% versus 2.8%, *P* less than 0.05) when carotid operation followed rather than preceded (2.8%, *P* less than 0.05) CABG, whereas mortality rates were similar (211). It is generally accepted that cerebral revascularization should precede coronary revascularization when significant carotid disease is known, except in the uncommon situation of the true emergency CABG patient, in whom carotid endarterectomy should then closely follow the heart operation.

Most workers in the field have focused on in-hospital neurological outcomes for treatment of combined carotid and coronary disease. Multicenter trials have shown an advantage of surgical over medical management for significant carotid stenosis in either symptomatic or asymptomatic patients (202,212-214). These data argue for an aggressive surgical approach in this population and demand a longer-range vision. The long-term outlook for combined treatment of carotid and coronary disease is shown in Figure 9. The above-suggested strategy for carotid disease management in the setting of CABG is in concordance with the *Guidelines for Carotid Endarterectomy: A Multidisciplinary Consensus Statement From the Ad Hoc Committee, American Heart Association [Special Report]* (215). The success of this long-term strategy is predicated on assembling a team that can achieve excellent near-term carotid and coronary surgical results (207,208,215-217).

Summary

Epivascular echocardiographic detection of ascending or transverse aortic atherosclerosis and modification of operative technique hold great promise for significant stroke risk

reduction. In the current era, important concurrent carotid and coronary disease should be suspected, sought by screening, and, when found, managed surgically (Table 13). This strategy neutralizes the short-term risk of treatment of either disease alone and enhances long-term quality and length of life for the patient with generalized atherosclerosis.

4.1.1.2. Type 2 Neurological Injury

Type 2 neurological complications have been identified in a percentage of patients after CABG and are associated with increases in postoperative time in the ICU, length of stay, hospital costs, and the need for postdischarge transfer to rehabilitation or extended-care facilities (48,218). Newman identified abnormal neurocognitive function in 53% of CPB-CABG patients at the time of hospital discharge. Six months after surgery, abnormalities could be identified in 24% of patients, which suggests some reversibility of the injury in some patients. However, they were able to measure cognitive decline in 42% of patients at 5 years. The strongest predictor of late decline was the presence of an abnormality early after CABG (218).

Abnormal neurocognitive function is frequently present preoperatively in the CABG population (219). There is a further decline in neurocognitive function after any major operation in this population, but this decline is likely worse and more persistent after operations employing CPB (220).

4.1.1.2.1. Reducing the Risk of Microembolization. Microembolization is a major contributor to postoperative cerebral dysfunction after CABG (221,222). Transcranial Doppler examination of the middle cerebral artery of patients on extracorporeal circulation suggests that most emboli occur during surgical manipulation (clamping, cannulation) of the ascending aorta (221,223,224). Many of these emboli appear to be gaseous, either derived from the oxygenator or entrained directly from the ambient atmosphere. Postmortem examination of the brains of patients dying soon after CPB has shown diffuse, small, capillary-arteriolar dilatations (225). These vacuolated vascular abnormalities have also been seen after catheter manipulation of the ascending aorta, suggesting an atheroembolic etiology. Fat droplets in shed mediastinal blood, which can be returned to the pump circuit via cardiotomy suction, may contribute (226). Small gaseous emboli could also be responsible for the findings. Neuroanatomists have postulated that these could impair circulation and lead to the neurocognitive decline seen after CPB.

The number of microemboli delivered during CPB is correlated with the postoperative neurocognitive decline seen immediately and 8 weeks after CPB (221). The use of a 40-micron arterial-line filter in the heart-lung machine circuit appears to be protective. Type 2 neurological outcomes may be further reduced by routine use of the membrane oxygenator rather than the less-expensive bubble oxygenator, which is still used selectively in the United States (190,227,228). The return of shed mediastinal blood to the CPB circuit via the cardiotomy suction system may increase the microembolic load to the brain. Some centers avoid cardiotomy suction and simply discard shed blood. Alternatively, shed blood may be scavenged and red blood cells returned after washing and centrifugation via cell-saving devices (226).

Some have believed that off-pump bypass surgery may reduce the incidence of type 2 neurological injury because ascending aortic cannulation and cross-clamping are avoided (229). Reports have demonstrated mixed results (54,56). In patients with significant ascending aortic atheromatous disease, it would seem prudent to consider an off-pump and "no touch" aortic technique. Inflow to graft conduits can be achieved via in situ left or right IMAs, the right gastroepiploic artery, or innominate and subclavian arteries.

4.1.1.2.2. Cerebral Hypoperfusion and Neurological Outcome. Intraoperative electroencephalographic monitoring can detect electrical patterns suggestive of cerebral hypoperfusion and allow real-time intraoperative correction. Decreases from 29% to 44% to 4% to 5% in postoperative neurocognitive and neuropsychological dysfunction (type 2) have been demonstrated by intraoperative electroencephalographic monitoring (230,231). However, the level of training necessary for interpretation of the electroencephalogram and the poor suitability of current technology for the operating room currently preclude its general clinical use for detection of hypoperfusion. Also, the electrical changes associated with microembolization and macroembolization are at the limits of resolution. The limitations cited reinforce the importance of strategies to prevent embolization.

Cerebral blood flow during CPB is kept relatively constant over a wide range of systemic arterial pressures with the alpha-stat extracorporeal circulation acid-base management technique. The incidence of persistent, postoperative neurocognitive deficits at 2 months with the use of this technique is significantly less compared with the alternative (pH-stat) technique (27% of patients versus 44%, P equals 0.047) (232).

4.1.1.2.3. Potentiators of Adverse Neurological Outcome. If neuroprotective mechanisms fail, there are strategies to minimize damage to the marginally perfused cerebral tissue, which has the potential for recovery. Cerebral hyperthermia potentiates the damage of an acute neurological injury. In the evolution of warm-heart surgery, some centers used techniques that had the potential for intraoperative cerebral hyperthermia. Techniques that have the patient "drift" on CPB toward ambient temperatures (34°C to 35°C or lower) rather than immediate warming (to maintain strict normothermia) allow an improved margin of neurological safety (233-236). During rewarming, arterial return blood temperature should be below 38°C. Hyperglycemia may also amplify the impairment caused by

Downloaded from circ.ahajournals.org by on August 4, 2008

an acute neurological event, emphasizing the importance of meticulous perioperative glucose monitoring and control (236).

Cerebral edema that may be present in patients immediately after extracorporeal circulation (237) may also potentiate CNS damage. Efforts to reduce the potential for brain swelling include maintenance of an unobstructed pathway for venous drainage to the CPB reservoir while on the pump. Anti-inflammatory strategies for CPB may reduce interstitial edema and are discussed subsequently, but pulsatile perfusion does not appear to be protective (238-240).

4.1.2. Reducing the Risk of Perioperative Myocardial Dysfunction

Most modern myocardial protection techniques allow the patient undergoing CABG to leave the operating room without a significant perioperative decrement in myocardial performance. Ideally, the surgeon is familiar with the broad range of myocardial protection principles that allow the adaptation of technique to accommodate varying patient presentations (241,242). There is no substitute for a well-orchestrated, technically sound, expeditious operation to minimize risk.

4.1.2.1. Myocardial Protection for the Patient With Satisfactory Preoperative Cardiac Function

The wide latitude of techniques associated with excellent results for the majority of patients undergoing CABG is testimony to the fact that there is no "ideal" or universally applicable myocardial protection technique (243). The greater the myocardial functional reserve in the patient population studied, the more difficult it is to demonstrate differences in myoprotective techniques. A variety of studies, including prospective trials, confirm the safety of many variations of cardioplegic arrest, which is the most widely used method for intraoperative myocardial protection. A single-center trial of cold crystalloid versus warm blood cardioplegia in 1001 patients undergoing elective CABG demonstrated a low perioperative MI rate (1.4% warm versus 0.8% cold, *P* not significant [NS]), IABP use (warm 1.4% versus cold, 2.0%, NS), and mortality (1.0% warm versus 1.6% cold, NS) with either technique (241). Advances in the understanding of myocardial and endothelial metabolism, temperature management, chemical/electrolyte composition, sanguineous or asanguineous delivery media, substrate enhancement, control of conditions of reperfusion, and delivery route have all led to important incremental advances in patient outcome (244-247). Certain techniques, however, offer a wider margin of safety for special patient subsets.

4.1.2.2. Myocardial Protection for Acutely Depressed Cardiac Function

Class I

Blood cardioplegia should be considered in patients undergoing cardiopulmonary bypass accompanying urgent/emergency CABG for acute MI or unstable angina. ***(Level of Evidence: B)***

In contrast to the patient with normal myocardial function, it is easier to demonstrate benefit from specialized protocols (248,249) in the patient with an acutely injured ventricle. One multicenter study of emergency CABG for patients with acute coronary occlusion (some with cardiogenic shock) demonstrated that controlled, surgical reperfusion with prompt, vented CPB and substrate-enhanced sanguineous cardioplegic technique led to a 96.1% survival, which approaches that seen in low-risk, elective CABG series (250). Preoperative regional wall-motion abnormalities improved after bypass in 87% of these patients despite an average of greater than 6 hours from infarct to revascularization.

Another observational study compared consecutive patients receiving cold crystalloid cardioplegia with a warm blood technique that did not include substrate enhancement in emergency CABG after failed angioplasty. There was a significant *reduction in MI* with the sanguineous technique (65% infarcts with crystalloid versus 26% for blood, *P* less than 0.007) (251). Multivariate analysis confirmed normothermic blood cardioplegia as an independent predictor of freedom from infarct in this study (*P* less than 0.005). Prospective, randomized trials have shown a *survival benefit* for patients treated with blood cardioplegia compared with crystalloid cardioplegia in the setting of urgent revascularization for unstable angina. In one trial, the operative mortality (0% versus 5%), incidence of MI (4% versus 13.5%), and low-output syndrome (10% versus 19%) were favorably reduced in patients receiving blood cardioplegia versus crystalloid (252). Multivariate analysis confirmed that crystalloid cardioplegia (*P* equals 0.008) was a significant, independent predictor of postoperative morbidity compared with warm-blood cardioplegia (253).

4.1.2.3. Protection for Chronically Dysfunctional Myocardium

Class IIa

Blood cardioplegia is probably indicated in patients undergoing cardiopulmonary bypass accompanying CABG in the presence of a chronically dysfunctional left ventricle. ***(Level of Evidence: B)***

Severe LV dysfunction is an important risk factor for patients undergoing CABG (254). Efforts to document reduction of risk in this cohort are confounded by incomplete data on the prevalence of reversible ischemic systolic dysfunction (hibernating myocardium) and the contribution of improved function from revascularization of myocardium as opposed to myocardial protection strategies (255). There is an emerging consensus, however, that for the chronically impaired ventricle, there is an added margin of safety provided by blood cardioplegic techniques (255-257). Its theoretical advantages include superior buffering capacity, rheo-

Downloaded from circ.ahajournals.org by on August 4, 2008

0209
09/15/08

logical considerations at the capillary level, and free-radical control when compared with crystalloid cardioplegia.

4.1.2.4. Cardiac Biomarker Elevation and Outcome

Class IIb

Assessment of cardiac biomarkers in the first 24 hours after CABG may be considered, and patients with the highest elevations of creatine kinase–MB (greater than 5 times upper limits of normal) are at increased risk of subsequent events. *(Level of Evidence: B)*

The importance of elevation of cardiac biomarkers in the first 24 hours after CABG has been controversial because some degree of elevation of creatine kinase–MB (CK-MB) is very common. New Q-wave MI after CABG occurs in 2% to 4% of patients and is associated with adverse outcome (258-260). However, up to 90% of individuals have some elevation of CK-MB (261). It has now been demonstrated that marked elevation of CK-MB (5-10 times upper limits of normal) is associated with an adverse prognosis. Increased risk of death and repeat MI in the first 30 days after CABG correlates with progressive increases in CK-MB elevation, with the worst outcome in those with levels greater than 5 times normal (262). Six-month (263) and 1-year (262) mortality also correlate with postoperative CK-MB elevation. Poorer outcomes, including heart failure and death, at an average of 3 to 5 years also appear to correlate with early cardiac biomarker elevation (261,264).

The prognostic value of troponins after CABG is not as well established, but available studies have suggested that troponin T is more discriminatory than CK-MB in predicting early complications (265). For patients with elevated biomarkers after CABG, it is particularly important that attention be given to optimal medical therapy, including the use of beta-blockers, angiotensin converting enzyme (ACE) inhibitors, antiplatelet agents, and statins in eligible individuals.

4.1.2.5. Adjuncts to Myocardial Protection

Class IIa

The use of prophylactic intra-aortic balloon pump as an adjunct to myocardial protection is probably indicated in patients with evidence of ongoing myocardial ischemia and/or patients with a subnormal cardiac index. *(Level of Evidence: B)*

The use of prophylactic IABP as an adjunct to myocardial protection may decrease mortality and overall resource utilization in certain high-risk patients. A retrospective evaluation of 163 consecutive patients with an LVEF less than or equal to 0.25 demonstrated a 4-fold reduction in 30-day mortality in patients treated with IABP. Thirty-day mortality was 2.7% in patients who received a prophylactic IABP placed preoperatively versus 11.9% for patients not receiving a balloon (P less than 0.005). IABP use was also associated with a shorter hospital stay and lower hospital charges (266). A randomized trial confirmed the benefit of preoperative IABP support in high-risk patients (35a). Placement of the IABP immediately before the operation afforded similar protection to that accompanying placement the day before CABG (267,268). In patients with severe PVD, a higher threshold for balloon use is required given the high complication rate in this patient group.

Appreciation of the role of the activated leukocyte in the genesis and exacerbation of myocardial reperfusion injury has led to strategies to remove leukocytes from the coronary blood flow. Clinical studies of leukocyte depletion have shown significant benefit to myocardial performance in the hypertrophied LV and in those with acute or chronic ischemia (269-273). However, leukocyte depletion as an adjunct to myocardial protection/reperfusion strategies has yet to achieve widespread recognition and use among surgeons; therefore, no consensus statement is appropriate at this point.

The long-term survival benefit afforded by use of the IMA is well recognized (12,274). Less appreciated is the reduction in immediate, operative mortality associated with the use of the mammary artery as opposed to saphenous vein revascularization. Its use may thus be considered an adjunct to myocardial protection. Its use should be encouraged in the elderly (275,276), the urgent/acutely ischemic patient (277), and other subgroups that previously were thought not to receive its immediate and long-term benefit. The large CABG database available to the STS (42) was analyzed for the influence of use of the IMA on operative mortality. Use of the IMA was associated with reduced operative mortality in all subgroups analyzed with regard to age (P less than 0.005), sex (P less than 0.005), priority of operation (P less than 0.005), normal (P less than 0.01) or reduced (P less than 0.005) LV function, presence of diabetes (P less than 0.005), obese patients (P less than 0.005), history of previous infarct (P less than 0.005), previous PTCA (P less than 0.001), and any pattern of coronary anatomy (P less than 0.005). Multivariate analysis also confirmed use of the IMA as an independent predictor of operative survival (P less than 0.0025). When risk factors were combined, the only groups found to have similar operative mortality between use/nonuse of the IMA were elective and nonelective *reoperative* patients greater than 70 years of age. Arterial conduits are discussed in more detail in Section 6.2.

4.1.2.6. Reoperative Patients

For patients undergoing repeat CABG surgery who previously have had a left IMA-to-LAD graft, a concern has been the accidental transection of the graft during sternotomy. However, one report from a high-volume center showed that experienced surgeons rarely encountered this complication (less than 3%) (278). The risk of death or serious myocardial dysfunction related to atheroembolism from patent, diseased SVGs is low in the current era and is attributable to recogni-

Downloaded from circ.ahajournals.org by on August 4, 2008

tion of the problem and careful operative techniques by experienced surgeons who encounter an increasing percentage of reoperative candidates in their practices (278). A risk-reducing strategy in this situation is the use of retrograde delivery of cardioplegia. This procedure allows early exclusion of atherosclerotic SVGs from the coronary circulation, as they are no longer needed to deliver cardioplegia.

4.1.2.7. Inferior Infarct With Right Ventricular Involvement

Class IIa

After infarction that leads to clinically significant right ventricular dysfunction, it is reasonable to delay surgery for 4 weeks to allow recovery. *(Level of Evidence: C)*

Right ventricular (RV) failure secondary to an ischemic RV (either infarction or stunning) presents a particularly hazardous situation (279). The prototypical patient has an occluded right coronary artery proximal to the major RV branches and presents with an inferior MI with or without recognized RV failure (280,281a,282-284). Angiography may demonstrate that the coronary anatomy is best treated surgically, but the opportunity for maximal benefit of an emergency operation (initial 4 to 6 hours) has often passed. There is substantial risk in operating after this small window of opportunity but before the recovery of RV function, which usually occurs at 4 weeks after injury (285). During this postinfarct month, the RV is at great risk for severe postoperative dysfunction, which often requires extraordinary levels of perioperative pharmacological and mechanical support and has a very high mortality. The nonsurgical postinfarction patient can most often be supported with pacing, volume loading, and judicious inotropic administration (286). In the surgical setting, the RV takes on different characteristics. There is loss of the pericardial constraint immediately on exposing the heart, which results in acute dilatation of the dysfunctional RV. The RV often fails to recover in this setting, even when state-of-the-art myocardial protection schemes and revascularization are employed (287). The parallel effects of RV dilatation and dysfunction on LV diastolic and systolic function are magnified and may be associated with the need for high levels of support, inability to close the chest owing to cardiac dilation, need for ventricular assist devices, prolonged convalescence, transplantation, or death (286a). In the acute setting, the potential risk of further RV injury must be weighed against the potential benefit of additional myocardial salvage. If early PCI of the right coronary artery is indicated, it should be performed (35a).

The best defense is an index of suspicion and recognition of the RV dysfunction by physical examination (281,288) electrocardiography (right precordial leads), echocardiography, or radionuclide-gated blood pool study (285,288-290). A successful early PCI may allow recovery of an infarcted RV in as few as 3 days (285).

4.1.3. Attenuation of the Systemic Sequelae of CPB

Extracorporeal circulation elicits a diffuse inflammatory response that is attended by a transient, multisystem organ dysfunction that may prolong convalescence (291,292). Numerous strategies have been shown to blunt this counterproductive immune response (291). Preoperative corticosteroid administration is inexpensive and appears to be efficacious. Corticosteroid administration has favorable effects on the systemic inflammatory response associated with extracorporeal circulation. Glucocorticoid, when given before CPB, reduces complement activation and the levels of proinflammatory cytokines (293-297). Compared with placebo, patients receiving glucocorticoid are less febrile postoperatively, have higher cardiac indexes, require less inotropic and volume support, and spend less time in the ICU (298-302).

Although there is no demonstration of an increased risk for infection in studies to date, it may be prudent to avoid the use of steroids in diabetic patients because the studies were not powered to detect modest increases in infection risk (301). The proper timing and duration of administration in this application are incompletely resolved; there is evidence that steroid delivery more in advance of an insult is more efficacious (303). Preoperative corticosteroid administration is inexpensive and appears to reduce the systemic inflammatory response associated with CPB with little downside risk. Current understanding supports liberal prophylactic use in patients undergoing extracorporeal circulation (293).

Aprotinin, a serine protease inhibitor known for its hemostatic characteristics, also attenuates complement activation and cytokine release during extracorporeal circulation. There appears to be an emerging role for its prophylactic use as an anti-inflammatory agent in patients undergoing CPB. There was a significant reduction in length of stay and hospital charges when aprotinin therapy was applied to a high-risk cardiac surgical population (291). By virtue of its effects on coagulation, aprotinin appears to reduce the need for transfusion after repeat CPB. However, there are insufficient data at present to make a strong recommendation for the routine use of this relatively expensive drug (293,297,304).

Perioperative leukocyte depletion through hematologic filtration may benefit patients by improving pulmonary function. One study suggested that low-risk patients benefit from a strategy of leukocyte depletion during CPB in conjunction with leukoreduction of homologous blood products (305-308). Although the literature does support the routine use of arterial-line filters to minimize microembolization in extracorporeal circulation, there is no current consensus on the value of selective leukocyte filtration for the CPB circuit. Although blood-surface interface modifications for the CPB circuit have also been shown to decrease markers of inflammation, translation into clinical benefit in terms of reduced morbidity, mortality, or resource utilization has been equivocal. The concern over thrombotic complications tempered enthusiasm among cardiac surgeons (291,309-313). Surface

Downloaded from circ.ahajournals.org by on August 4, 2008

0211
09/15/08

modification such as heparin-bonded circuitry for extracorporeal circulation holds promise for reduction of the systemic inflammatory response to CPB, but at present the evidence is sufficiently conflicting that firm recommendations are not at hand.

4.1.4. Reducing the Risk of Perioperative Infection

Class I

1. **Preoperative antibiotic administration should be used in all patients to reduce the risk of postoperative infection.** ***(Level of Evidence: A)***
2. **In the absence of complicating circumstances, a deep sternal wound infection should be treated with aggressive surgical debridement and early revascularized muscle flap coverage.** ***(Level of Evidence: B)***

Class IIa

The risk for deep sternal wound infection is reduced by aggressive control of perioperative hyperglycemia by using a continuous, intravenous insulin infusion (314). ***(Level of Evidence: B)***

Multiple opportunities exist to reduce infection risk in patients undergoing CABG. Interval reporting to individual surgeons of their respective wound infection rates leads to risk reduction through discipline in adherence to sterile operative techniques. Skin and nasopharyngeal Gram-positive organisms are the leading cause of the most threatening complication: deep sternal wound infection or mediastinitis. Skin preparation with topical antiseptics (315,316), clipping rather than shaving the skin (318,319), avoidance of hair removal (62), reduction of operating room traffic, laminar-flow ventilation, shorter operations, minimal electrocautery (320), avoidance of bone wax (321), use of double-gloving barrier techniques for the operating team (322-326), and routine use of an easily constructed pleuropericardial flap (327) have all been shown to be of value in reducing postoperative infection (314).

Several newer strategies that are easily integrated into practice deserve consideration. Diabetes mellitus afflicts 1 of 5 patients undergoing CABG and is an independent risk factor for wound infection (328). The risk for deep sternal wound infection is reduced by aggressive control of perioperative hyperglycemia (glucose levels greater than 150 to 180 mg/dL) by using a continuous intravenous regular insulin infusion (0.9% deep sternal wound infection) versus intermittent subcutaneous insulin treatment (1.9%, *P* equals 0.04) (314).

Homologous blood transfusions after CABG are correlated in a dose-related fashion to increased risk for viral and bacterial infections, increased length of stay, antimicrobial use, and mortality through transfusion-related immunomodulation (329,330). A retrospective study of 238 patients undergoing CABG demonstrated this immunosuppressive effect of transfusion. Wound and remote infections occurred in 4% of patients who received less than or equal to 2 U of red blood cells, in 7% of those transfused with 3 to 5 U, and in 22% of those having received greater than or equal to 6 U (329). Leukodepletion strategies have been shown to blunt the immunosuppressive effect of blood transfusion in surgical patients (330). The dose-related effect of blood transfusion on increased infection risk has been known for general surgical and orthopedic operations and is thought to be caused by the accompanying leukocytes in the red blood cell transfusion (331). A single-center prospective trial of 3 transfusion protocols in 914 patients undergoing cardiac surgery showed a significant reduction for patients receiving leukocyte-depleted blood (17.9%) as opposed to nonfiltered blood (23.5%, *P* equals 0.04) for all infections (respiratory, urinary tract, bacteremia, and wound) (330). Most striking was the reduction in 60-day mortality in transfused patients having received filtered blood: transfused/nonfiltered patient mortality was 7.8%; transfused/filtered at the time of donation, 3.6%; and transfused/filtered at the time of transfusion, 3.3% (*P* equals 0.019) (330). The reduction in the postoperative rate of noncardiac causes of death (i.e., multisystem failure) in leukocyte-depleted/transfused patients compared with patients receiving nonfiltered blood was highly significant (*P* equals 0.001) (330). Leukodepletion can be accomplished by regional blood banks at the time of donation or at the bedside at time of transfusion by using a relatively inexpensive in-line transfusion filter.

Preoperative antibiotic administration reduces the risk of postoperative infection 5-fold (332). Prophylactic antimicrobial efficacy is dependent on adequate drug tissue levels before microbial exposure (333,334). Multi-institutional studies suggest that many centers, including those with training programs in cardiothoracic surgery, are not consistent in delivering or teaching effective use of perioperative antibiotics.

The cephalosporin class of antimicrobials is currently the agent of choice for prophylaxis of infection for coronary operations. There is a trend toward superior efficacy with cefuroxime compared with the other cephalosporins, but this difference does not reach statistical significance (Table 14) (334-338). Institution- or surgeon-specific selection is appropriate within this class (335). Data suggest that a 1-day course of intravenous antimicrobials is as efficacious as the traditional 48-hour (or longer) regimen (339-342). There is little evidence that prolonging (greater than 2 days) the antimicrobial prophylaxis even in high-risk patients provides any benefit (343). A 1-day course of antimicrobial prophylaxis is safe and effective (344). There are insufficient data to suggest that aminoglycosides add substantial benefit to the antimicrobial prophylactic regimen (335). Usual cephalosporin pharmacokinetics mandates administration within 30 minutes of incision and redosing if the operation exceeds 3 hours (335,345).

Antimicrobial selection is a moot point if the agent is not delivered during the optimal 30- to 60-minute window just before incision. The beneficial effect is negated if the drug is

Downloaded from circ.ahajournals.org by on August 4, 2008

Table 14. Prophylactic Antimicrobials for Coronary Artery Bypass Graft Surgery

Antibiotic	Equivalent Efficacy IV Dosing Regimen Dose and Interval	Cost per Dose	Comments
Cefuroxime	1.5 g preoperatively 1.5 g after CPB 1.5 g Q12×48	$6.33/1.5 g	First-line agents; low toxicity; pharmacokinetics vary; shorter prophylaxis duration less than 24 h may be equally efficacious for cefuroxime
Cefamandole, cefazolin	1 g preoperatively 1 g at sternotomy 1 g after CPB 1 g Q6×48 (Initial dose to be given 30-60 minutes before skin incision)	$6.27/g $0.90/g	
Vancomycin	1 g Q12/h/until lines/tubes out At least 2 doses (During 30-60-minute infusion timed to end before skin incision)	$5.77/g	Reserved for penicillin-allergic; justified in periods of methicillin-resistant *Staphylococcus* species outbreaks; vancomycin-resistant *Enterococcus* problem is on horizon; more likely to require vasopressor agent perioperatively

CPB indicates cardiopulmonary bypass. Data derived from References 334 and 336-338.

given after incision. This is a major issue. A multi-institutional study, including those with cardiothoracic training programs, confirmed the suboptimal use of prophylactic antimicrobials. In 1994, only 23% of the institutions studied had a system that assured proper administration of prophylactic antimicrobials in the generous 2-hour period just before incision for patients undergoing CABG. One year later, compliance was even worse at 20% (346). A practical, fail-safe guideline to assure proper timing is the administration of the cephalosporin by the anesthesiologist after induction but before skin incision. Then the surgeon confirms administration before the scalpel is in hand (334,347). Surgeons should be familiar with the pharmacokinetics of their preferred cephalosporin to modify initial and subsequent dosing based on patient size and duration of operation. This knowledge can favorably influence plasma, sternal, and soft-tissue bacteriocidal activity for the individual patient.

If preventive strategies fail, prompt recognition of deep sternal wound infection or mediastinitis is critical. Morbidity and mortality for deep sternal wound infection or mediastinitis have decreased over the past 20 years for several reasons. Aggressive surgical debridement and early vascularized muscle flap coverage are key to reducing the cost, length of stay, and mortality (348,349). A prospective trial has lessened debate on proper management of the deeply infected sternotomy incision. Treatment by wound exploration, sternal rewiring, and drainage failed in 88.2% of patients compared with high success in patients treated initially with muscle flap closure (350).

4.1.5. Prevention of Postoperative Arrhythmias

Class I

Preoperative or early postoperative administration of beta-blockers in patients without contraindications should be used as the standard therapy to reduce the incidence and/or clinical sequelae of atrial fibrillation after CABG. *(Level of Evidence: B)*

Class IIa

1. **Preoperative administration of amiodarone reduces the incidence of postcardiotomy atrial fibrillation and is an appropriate prophylactic therapy for patients at high risk for postoperative atrial fibrillation who have contraindications to therapy with beta-blockers. *(Level of Evidence: B)***
2. **Digoxin and nondihydropyridine calcium-channel blockers are useful for control of ventricular rate but at present have no indication for prophylaxis. *(Level of Evidence: B)***

Class IIb

Low-dose sotalol can be considered to reduce the incidence of atrial fibrillation after CABG in patients who are not candidates for traditional beta-blockers. *(Level of Evidence: B)*

Postoperative atrial fibrillation increases the length of stay after CABG up to 5 days (351), increases the charges by as much as $10 055 (351), and is associated with a 2- to 3-fold increase in postoperative stroke (182,183).

Table 15. Pharmacological Strategies for Prevention of Atrial Fibrillation After Coronary Artery Bypass Graft Surgery

Treatment	Timing	Dose/Route	AF Incidence, %	Comments	Evidence (Reference)
Frontline strategies					
Resumption of patient's preoperative beta blocker	Postoperative resumption	Same as preoperative	Beta-blocker stopped 38.1% Continued 17.1%; P= 0.02	Resumption of beta-blocker reduced AF by 45%	randomized trial (782)
			Beta-blocker stopped 28%; Continued 6%; P= 0.01	Nearly 5-fold decrease in incidence; if no longer needed after revascularization, may taper as outpatient	randomized trial (783)
• Beta blockers (propranolol prototypical)	Postoperative initiation (10±7 h postoperatively)	5 mg Orally 4 times per day	Control 23%; Propranolol 9.8%; P=0.02	Reduced AF by 43%; inexpensive, low dose	randomized trial (784)
• Almost all beta blockers evaluated	Postoperatively	Varies	Significantly reduced versus placebo	Odds ratio 0.17; confidence interval 0.03–0.98 in favor of beta blocker over controls in meta-analysis	randomized trial (785,786) metanalysis (355)
Atenolol	Preoperatively (begun 72 h before operation)	50 mg Orally twice a day	Control 37%; Atenolol 3%; P=0.001	Excellent option if preoperative phase practical	metanalysis (355)
Sotalol	Preoperatively through postoperatively	160 mg AM of operation, then 160 mg BID PO	Control 29% Sotalol 10%	Class III properties; sotalol not tolerated in 10% of patients	randomized trial (787)
Magnesium sulfate	Postoperatively	Continuous IV infusion for a total of 178 mEq over first 4 postoperative days	Control 28%; Mg supplement 14%; P =0.02	Goal is normal serum magnesium: =1 mmol/L, < 2 mEq/L, which is usually low after cardiopulmonary bypass	prospective trial (788)
Alternative/niche strategies					
Amiodarone	Preoperatively through postoperatively	600 mg Orally daily for 7 days preoperatively; then 200 mg PO daily postoperatively; stop at discharge; total = 4.8 g	Control 53%; Amiodarone 25%; P=0.003	Mixed group of coronary and valve patients, explaining very high AF incidence	prospective trial (356)
Amiodarone	Postoperatively	300 mg Intravenous bolus; then 1.2 g over 24 h for 2 days; then 900 mg every 24 h for 2 days, for a total of 4.5 g	Control 21%; Amiodarone 5%; P=0.05	Coronary bypass patients only in this study	prospective trial (789)
Propafenone	Postoperatively	300 mg Orally twice a day for 7 days	Propafenone 12%; Atenolol 11%; P=NS	Propafenone offers a less negative inotropic option for poor left ventricular function population	prospective trial (354)
Triiodothyronine (T3)	Intraoperative	0.8 mcg/kg IV after cross-clamp then IV infusion 0.113 mcg/kg/hr × 6hr	Control 46%; T3 24%; P = 0.009	All patients in this study had depressed LV function	randomized trial (790)

Treatment	Timing	Dose/Route	AF Incidence, %	Comments	Evidence (Reference)
Strategies not clearly efficacious for prophylaxis					
digoxin	Preoperative	oral	Control 17.6%; Digoxin 14.2%; *P* = NS	Doesn't significantly reduce AF but does control ventricular rate for AF	prospective trials (791,792)
				digoxin = 139/min control = 161/min *P* = 0.02	metanalysis (355)
Calcium channel blockers • verapamil	Postoperative	oral	Control 18.2%; Verapamil 18.2%; *P* = NS	Does not significantly reduce AF but does control ventricular rate if AF established: verapamil = 131/min; control = 155/min; *P* = 0.002	prospective trials (793-795) metanalysis (355)

The causal and temporal relationship among atrial fibrillation after CABG, the incidence of new left atrial thrombus, and the potential for embolism and stroke remains ill-defined. However, if atrial fibrillation after CABG persists into a second day, warfarin anticoagulation with a goal of an international normalized ratio (INR) of 2.0 to 3.0 should be considered (352).

Withdrawal of beta-blockers in the perioperative period doubles the incidence of postoperative atrial fibrillation after CABG. One series showed that 40 of 105 patients who had withdrawal of beta-blockers developed postoperative atrial fibrillation compared with 18 of 105 patients who had early postoperative reinstitution of beta-blocker (*P* equals 0.02). Virtually every study of beta-blockers administered for the purpose of reducing postoperative atrial fibrillation has shown benefit. Most trials have examined the initiation of prophylaxis in the postoperative period. There appears to be an even greater benefit if beta-blockers are begun before operation. For example, in 1 controlled trial, atenolol started 3 days before operation led to a reduction of atrial fibrillation from 37% in the control group to 3% in the atenolol group (*P* equals 0.001) (Table 15) (353,354).

Low-dose sotalol can also be considered effective for reduction of atrial fibrillation after CABG. In a prospective, double-blind, randomized, placebo-controlled study, the placebo group had an incidence of supraventricular arrhythmias of 43% compared with 26% for sotalol (*P* equals 0.0012, or a 43% reduction) (355).

Amiodarone administered beginning 1 week before surgery reduces the incidence of postcardiotomy atrial fibrillation (53% with placebo to 25% with amiodarone, *P* equals 0.003), reduces hospital costs ($26 000 to $18 000, *P* equals 0.03), and shortens the length of stay (8 to 6.5 days, *P* equals 0.04) (356). This represents another option for patients undergoing elective CABG who have contraindications to beta-blocker therapy.

The Atrial Fibrillation Suppression Trial (AFIST) was a prospective study of patients aged 60 years or older (average age 73 years) undergoing open-heart surgery who were randomized to oral amiodarone therapy or placebo given in addition to beta-blockers (357). Patients received up to a total of 3 grams of oral amiodarone in divided doses 1 to 4 days before to surgery and continued 400 mg by mouth twice a day for 4 days after surgery. The patients who were given amiodarone had a lower frequency of any atrial fibrillation (22.5% versus 38.0%; *P* equals 0.01), symptomatic atrial fibrillation (4.2% versus 18.0%, *P* equals 0.001), cerebrovascular accidents (1.7% versus 7.0% *P* equals 0.04), and postoperative ventricular tachycardia (1.7% versus 7.0%) (357).

Digoxin and nondihydropyridine calcium channel blockers (verapamil has been the most extensively studied) are useful for control of ventricular rate but have no consistent benefit for prophylaxis of supraventricular arrhythmias after CABG (Table 15) (355). Currently, preoperative or early postoperative administration of beta-blockers is considered standard therapy to prevent atrial fibrillation after CABG except in patients with active bronchospasm or marked resting bradycardia.

4.1.6. Strategies to Reduce Perioperative Bleeding and Transfusion

Despite the increasing safety of homologous blood transfusion, patients and their families are often far more concerned

Downloaded from circ.ahajournals.org by on August 4, 2008

about transfusion risk than MI, stroke, or death after CABG. Well-publicized cases of transmission of viral illness with transfusion after cardiac operation in the early 1980s have sensitized the North American population. A study of donors who passed current blood donor screens but subsequently seroconverted suggests a current risk for donation of blood during an infectious period of 1/493 000 for human immunodeficiency virus, 1/641 000 for human T-cell lymphotrophic virus, 1/103 000 for hepatitis C virus, and 1/63 000 for hepatitis B virus (358).

Cardiac surgical patients account for 10% of blood transfusions in the United States (359). Twenty percent of patients having cardiac operations use 80% of the blood products attributed to cardiac surgical use. Several of the short-term, deleterious effects of transfusion were discussed in the section on reducing infection (360). Predisposing risk factors for transfusion after CABG include advancing age, lower preoperative red blood cell volume, preoperative aspirin therapy, priority of operation, duration of CPB, recent fibrinolytic therapy, reoperative CABG, and differences in heparin management (361-367). Institutional protocols with thresholds for transfusion lead to an overall reduction in the number of units transfused and the percentage of patients receiving any blood (368).

Aspirin, a very common preoperative medication in patients undergoing CABG, decreases platelet aggregation and increases postoperative blood loss. The magnitude of this effect has been confirmed in prospective, controlled trials (369). Preoperative aspirin is associated with increased risk for transfusion, prolonged wound closure time, and an increase in early reoperation for bleeding (370). The value of aspirin in the treatment of acute coronary syndromes will often outweigh the increased risk for perioperative bleeding should coronary bypass be indicated early in the course of the acute event. In certain patients in an appropriate clinical setting, including chronic stable angina, low-risk plaque morphology, and others, cessation of aspirin and other platelet inhibitors 7 to 10 days before elective cardiac operation appears prudent to decrease the risk of postoperative bleeding and transfusion. For clopidogrel, the recommendation is to discontinue the agent 5 or more days before surgery when the clinical situation will permit it (see Section 5.11).

Aprotinin, a serine protease inhibitor with antifibrinolytic activity, significantly decreases postoperative blood loss and transfusion requirements (both units and number of patients) in high-risk, patients undergoing primary CABG, those on aspirin, and in particular the population undergoing reoperative bypass (371,372). Aprotinin does not appear to decrease early graft patency after coronary bypass despite its benefit in reducing postoperative bleeding and need for blood transfusion (373,374). Mechanical strategies to reduce the need for homologous blood have been only marginally successful.

Both epsilon-aminocaproic acid and an analogue, tranexamic acid, have antifibrinolytic activity. Both have been demonstrated to decrease mediastinal drainage after cardiac operation (375-378). Demonstration of a reduction in transfusion requirements has been inconsistent, however (376). Although these agents are relatively inexpensive, the data are insufficient to recommend their routine use. In contradistinction to aprotinin, the safety regarding the thrombotic potential including graft patency issues is unresolved (374,379). The concept of risk stratification for transfusion requirements has been validated (380) and offers a more rational approach to risk reduction strategies seeking to minimize blood requirements (380).

Efforts to synthesize multiple blood-conservation methods have proven successful in reducing transfusion (381). The most fully evolved protocol using multiple mechanical and pharmacological means achieved a remarkable series of 100 consecutive, selected patients undergoing CABG without transfusion (382). Intrinsic to this strategy was the concept of varying risk for transfusion and an individualized, algorithm-driven approach for the patient undergoing elective CABG. Models for prediction of the need for transfusion postoperatively allow shepherding of resources and application of risk-neutralizing strategies to those more likely to benefit (383). Comparison was made with a consecutive series of concurrent patients with the same transfusion criteria. The multi-modality conservation patients had no transfusion compared with 38% of the concurrent control group who received an average of 2.2 plus or minus 6.7 U of blood. Mediastinal drainage for the conservation group was half that of the control group (370 plus or minus 180 versus 660 plus or minus 270 mL, P equals 0.001) (382). Costs were similar between groups. The liberal use of aprotinin (69% of patients), exclusion of anemia patients, and minimal hemodilution appear to be the keys to these results.

Prehospitalization autologous blood donation can be effective. If a patient has no exclusionary criteria (hemoglobin less than 12, heart failure, unstable angina, left main disease, or symptoms on the proposed day of donation) and can achieve 1 to 3 U of donated blood over 30 days before operation, the risk of homologous transfusion is significantly lowered (12.6% versus 46% in a non-preadmission donor control group, P equals 0.001). An alternative or additional method of pre-CPB blood "donation" is the removal of blood from the patient in the operating room immediately before CPB. This blood is then set aside, not exposed to the CPB circuitry, and then reinfused into the patient after the patient is disconnected from CPB. This donation immediately before CPB yielded a significantly higher platelet and hemoglobin count in 1 study (P less than 0.01) compared with similar postoperative levels in patients who did not undergo harvesting of blood immediately before CPB. In this study, this technique translated into a 6-fold decrease in the percentage of patients requiring transfusion (10% transfusion rate in pre-CPB donors versus a 65% transfusion rate in non–pre-CPB donors, P less than 0.01) (384).

A multicenter, prospective study of recombinant human erythropoietin given over a 5-day course failed to demonstrate a significant reduction in transfusion requirement,

Downloaded from circ.ahajournals.org by on August 4, 2008

although a significant rise in preoperative hemoglobin (*P* less than 0.05) was noted (385).

A randomized, placebo-controlled trial demonstrated no advantage of iron supplementation for restoration of red blood cell mass after coronary bypass, but the patients receiving iron did have significantly more gastrointestinal complaints (379,384).

Autotransfusion has had a generally favorable effect on decreasing allogeneic blood use, but concerns about stimulation of fibrinolysis with reinfusion of shed mediastinal blood prevent unequivocal recommendations on its use, particularly in routine low-risk patients (386).

4.1.7. General Management Considerations

Acuteness of operation is an important determinant of operative morbidity and mortality. The need for an emergent or even urgent operation can often be forestalled by appropriate pharmacological therapy, placement of an IABP, or even percutaneous revascularization of "culprit" stenoses. In each instance, the benefit of temporizing therapy must be weighed against the risk of waiting and the risk of the therapy used to achieve delay. A discussion of this strategy as applied to the acute coronary syndrome is presented in Section 5.11. Smoking cessation and improvement of chronic bronchitis before elective coronary operation lessen the risk for perioperative pulmonary complications (305). Preoperative pulmonary edema is a particularly hazardous situation, as extracorporeal circulation will worsen the lung water and predispose the patient to prolonged, postoperative mechanical ventilatory support. Ideally, the operation is deferred until resolution of the edema is accomplished. Obesity is an independent risk factor for perioperative respiratory failure, sternal and leg wound complications, perioperative MI, and arrhythmias (387). If the patient's coronary anatomy and clinical course permit, a concerted effort at weight reduction is appropriate and operation is deferred.

4.2. Maximizing Postoperative Benefit

4.2.1. Antiplatelet Therapy for SVG Patency

Class I

Aspirin is the drug of choice for prophylaxis against early saphenous vein graft closure. It is the standard of care (Table 13) and should be continued indefinitely given its benefit in preventing subsequent clinical events. ***(Level of Evidence: A)***

Aspirin significantly reduces vein graft closure through the first postoperative year. A demonstrable effect on arterial graft patency has not been demonstrated. Aspirin administration before operation offers no improvement in subsequent vein graft patency compared with early postoperative initiation (370). Fail-safe mechanisms should exist to ensure prompt postoperative initiation of aspirin therapy. Prospective controlled trials have demonstrated a graft patency benefit when aspirin was started 1, 7, or 24 hours after operation (388-390). The benefit of postoperative aspirin on SVG patency is lost when started greater than 48 hours after surgery (391). Dosing regimens ranging from 100 to 325 mg daily appear to be efficacious. As the graft recipient coronary artery luminal diameter increases, SVG patency rates improve and the advantage of aspirin over placebo is reduced (392). Aspirin, given early after CABG (within 48 hours) has been shown to significantly reduce subsequent mortality, MI, stroke, renal failure, and bowel infarction (393).

Ticlopidine is efficacious (394) but offers no advantage over aspirin except as an alternative in the truly aspirin-allergic patient. Life-threatening neutropenia is a rare but recognized side effect. When ticlopidine is used, white blood cell count should be periodically monitored in the early months after initiating treatment. Clopidogrel offers the potential for fewer side effects compared with ticlopidine as an alternative to aspirin for platelet inhibition. The incidence of severe leukopenia is rare and similar to that of aspirin in a controlled trial (395). Indobufen is a reversible inhibitor of platelet cyclooxygenase, in contradistinction to aspirin, so platelets recover function within 24 hours of cessation of the drug. It appears to be as effective as aspirin for saphenous graft patency over the first postoperative year but with fewer gastrointestinal side effects (396).

Dipyridamole adds nothing to the aspirin effect for saphenous graft patency (370). Warfarin has shown no consistent benefit in maintaining saphenous graft patency (397) and may be associated with an increased risk for bleeding compared with antiplatelet therapy for this application (398). Whether the combination of aspirin and clopidogrel is superior to aspirin alone is not yet resolved.

In summary, aspirin is the drug of choice for prophylaxis against early saphenous graft thrombotic closure. Perioperative use and/or administration of aspirin within 48 hours of operation should be the standard of care (Table 13) and should be continued indefinitely, given its benefit in the secondary prevention of subsequent clinical events.

4.2.2. Pharmacological Management of Hyperlipidemia

Class I

All patients undergoing CABG should receive statin therapy unless otherwise contraindicated. ***(Level of Evidence: A)***

There is little question that patients with known atherosclerotic disease, including patients undergoing CABG for coronary atherosclerosis, should receive lipid-lowering therapy. If there is no contraindication, statin (3-hydroxy-3-methylglutaryl coenzyme A reductase inhibitor) therapy is recommended as initial therapy to lower the low-density lipoprotein cholesterol (LDL-C). How low should the LDL-C be lowered? The Adult Treatment Panel III of the National Cholesterol Education Program (NCEP) continues to recommend that the LDL-C goal should be less than 100 mg/dL

Downloaded from circ.ahajournals.org by on August 4, 2008

0217
09/15/08

(399). This recommendation as applied to the CABG patient is supported by the Post Coronary Artery Bypass Graft Trial Investigators. Angiographic progression of atherosclerotic vein-graft disease was significantly retarded by lovastatin (with the occasional addition of cholestyramine to achieve the individualized lipid-lowering goal). Patients having aggressive cholesterol lowering (achieved LDL-C less than 100 mg/dL) had disease progression in 29% of saphenous grafts over an average 4-year follow-up compared with 39% in the moderate treatment group (achieved LDL-C less than 140 mg/dL) (*P* less than 0.001) (397). The aggressively treated group had a lower repeated revascularization rate over the course of the study compared with the moderate treatment cohort: 6.5% versus 9.2% (29% lower, *P* equals 0.03).

The Heart Protection Study, which prospectively studied 20536 patients in a double-blind trial of simvastatin 40 mg daily versus placebo, showed significant benefit of statin therapy even in individuals with LDL-C less than 100 mg/dL (400). Thus, either the LDL-C goal of 100 mg/dL is too high (studies are under way to compare the effect of an LDL-C–lowering goal of 100 mg/dL versus 70 mg/dL) or the pleomorphic benefits of statin therapy are present regardless of the LDL-C level. Based upon the results of the PROVE-IT trial, the NCEP has recently recommended an LDL-C goal of less than 70 mg/dL in patients deemed to be at very high risk (399a). Because patients are more likely to continue on statin therapy begun in the hospital (401), it is recommended that statin therapy be continued or started during hospitalization for CABG surgery.

If the patient is on statin therapy and the LDL-C goal has been reached prior to CABG surgery, attention should be directed to elevated triglycerides and low high-density lipoprotein cholesterol (HDL-C). These dyslipidemias, especially when combined with an elevated fasting glucose, central obesity, and hypertension, constitute the cardiovascular metabolic syndrome, a syndrome that along with diabetes, is associated with excess cardiovascular mortality and morbidity. These patients should be treated with diet, weight control, daily exercise, and drug therapy designed to increase HDL-C and decrease triglycerides. The recommendations of ATP-III should serve as a guideline (399). Those patients with the insulin resistance syndrome or diabetes often need additional therapy with ACE inhibitors or angiotensin receptor blockers to protect their renal function.

Patients with a strong family history of coronary disease and patients undergoing CABG surgery with completely normal or low lipid levels without recent illness or lipid-lowering therapy should be screened for elevated novel risk factors such as homocysteine, lipoprotein(a), hs–C-reactive protein, and fibrinogen (402).

4.2.3. Hormonal Manipulation

Class III

Initiation of hormone therapy is not recommended for women undergoing CABG surgery. *(Level of Evidence: B)*

Although more than 30 observational studies have shown a reduced mortality for coronary disease in postmenopausal women on hormone replacement therapy, hormone therapy (HT) is no longer recommended for women undergoing CABG surgery.

The Heart and Estrogen/Progestin Replacement Study (HERS) randomized postmenopausal women less than 80 years of age with CAD to placebo (1a,405) or estrogen/progestin HT (1a,397). Forty-two percent of the patients underwent CABG surgery (405). The primary end point was nonfatal MI and CAD deaths. The patients were followed up for 4.1 years. There was no statistical difference in the primary end points, but there were more cardiovascular disease deaths in the patients receiving HT (71 versus 58). There were significantly more patients with deep vein thrombosis (*P* equals 0.004) and any thromboembolic events (*P* equals 0.002) in the women receiving HT.

The reason for the marked discrepancy between the observational studies and this large controlled trial probably relates to the fact that although HT does offer long-term protection from cardiovascular disease, it increases the risk of clotting. Therefore, patients with MI undergoing PCI or CABG surgery should not be started on HT. Patients on HT should have therapy discontinued if undergoing surgery or prolonged bed rest secondary to an illness such as a stroke.

4.2.4. Smoking Cessation

Class I

1. **All smokers should receive educational counseling and be offered smoking cessation therapy after CABG. *(Level of Evidence: B)***
2. **Pharmacological therapy including nicotine replacement and bupropion should be offered to select patients indicating a willingness to quit. *(Level of Evidence: B)***

Smoking is the single most important cause of preventable premature mortality in the United States (406). There is strong evidence from the CASS that smoking cessation after coronary bypass is rewarded by less recurrent angina, improved function, fewer hospital admissions, maintenance of employment, and improved survival (84% survival for quitters versus 68% for persistent smokers at 10 years for those randomized to operation) (*P* equals 0.018) (407). Cessation of smoking after coronary bypass improves the postoperative survival of successful quitters to that of post-bypass patients who have never smoked; persistent smokers have significantly more MIs and reoperations (408). As expected, smoking leads to angiographically detected deterioration over time: only 39% of smokers' saphenous grafts are disease-free at 5 years compared with 52% of nonsmokers (409).

Failure to attempt cessation and recidivism are the difficult issues. Treatment individualized to the patient is crucial. Smoking is an addictive disorder and should be treated as

Downloaded from circ.ahajournals.org by on August 4, 2008

such and not as an indication of self-destructiveness or weak willpower (410).

Depression is an important complicating factor in smoking and may account for a significant number of cessation failures (411,412). Behavioral treatments alone are not as effective as drug therapy (413).

The nicotine transdermal patch is effective in smoking cessation treatment. The average cost per year of life saved ranges from $965 to $2360 (406). A transdermal nicotine patch in conjunction with a behavioral modification program sustained continuous abstinence for 20% of patients receiving the patch versus 9% for those receiving behavioral modification alone (414). Nicotine gum added to transcutaneous patch therapy significantly increased abstinence rates above that of the active patch alone at 52 weeks (415).

A sustained-release form of the antidepressant bupropion is effective for smoking cessation in a dose-related fashion. The agent reduces the nicotine craving and anxiety of smokers who quit. Three hundred milligrams per day led to a 44% smoke-free rate at 7 weeks and 23% at 1 year, double that of the placebo group (P less than 0.001) (412). The results at 1 year parallel those seen with nicotine replacement strategies. As with any drug, the patient started on bupropion should be monitored for adverse side effects.

In summary, all smokers should receive educational counseling and be offered smoking cessation therapy, including pharmacological therapy if appropriate, after coronary bypass (Table 16) (416). Pharmacological therapy including nicotine replacement and bupropion should be offered to patients indicating a willingness to quit.

Table 16. Smoking Cessation for the Primary Care Clinician

Strategy 1. Ask—systematically identify all tobacco users at every visit.
- Implement an office-wide system that ensures that for EVERY patient at EVERY clinic visit tobacco-use status is queried and documented.

Strategy 2. Advise—strongly urge all smokers to quit.
- In a clear, strong, and personalized manner, urge every smoker to quit.
- Ask every smoker if he or she is willing to make a quit attempt at this time.

Strategy 3. Assist—aid the patient in quitting.
- Help the patient with a quitting plan.
- Encourage nicotine replacement therapy or bupropion except in special circumstances.
- Give key advice on successful quitting.
- Provide supplementary materials.

Strategy 4. Arrange—schedule follow-up contact
- Schedule follow-up contact, either in person or via telephone.

From the ACC/AHA 2002 Guideline Update on the Management of Patients With Stable Angina that was modified from Fiore MC, Bailey WC, Cohen JJ, et al. Smoking Cessation. Clinical Practice Guideline Number 18. AHCPR publication No. 96-0692. Rockville, MD: Agency for Health Care Policy and Research, Public Health Service, U.S. Department of Health and Human Services, 1996.

4.2.5. Cardiac Rehabilitation

Class I

Cardiac rehabilitation should be offered to all eligible patients after CABG. *(Level of Evidence: B)*

Cardiac rehabilitation including early ambulation during hospitalization, outpatient prescriptive exercise training, family education (417), and sexual counseling (418) have been shown to reduce mortality (419,420). Cardiac rehabilitation beginning 4 to 8 weeks after coronary bypass and consisting of 3-times-weekly educational and exercise sessions for 3 months is associated with a 35% increase in exercise tolerance (P equals 0.0001), a slight (2%) but significant (P equals 0.05) increase in HDL-C, and a 6% reduction in body fat (P equals 0.002) (421). Exercise training is a valuable adjunct to dietary modification of fat and total caloric intake in maximizing the reduction of body fat while minimizing the reduction of lean body mass (422). A significant hurdle appears to be *initiation* of rehabilitation. In a prospective study of recruitment for a comprehensive cardiac rehabilitation program for patients having just undergone coronary bypass, only 52 of 393 elected to participate. Participation was lower for women (26% of nonparticipants versus 12% of enrolled, P equals 0.02), unemployed patients (63% of those declining versus 45% of the participants, P equals 0.02), those with a lower income and educational level (both P equals 0.001), and those with a greater functional impairment (P equals 0.001) (423). If the barriers to enrollment can be overcome, benefits seem to accrue to all special groups studied. The benefits of cardiac rehabilitation extend to the elderly and to women (424,425). Despite the fact women have a generally higher risk profile and a relatively lower functional capacity than men at initiation of a rehabilitation period (426), there were similar compliance and completion rates, and women achieved a similar or greater improvement in functional capacity (women increased peak metabolic equivalents by 30%, men by 16%, P less than 0.001) (427). Medically indigent patients appear to have rehabilitation compliance and benefit rates on par with insured/private-pay patients if rehabilitation is initiated and appropriately structured (428).

In a long-range trial focused exclusively on a coronary bypass population, postoperative patients were randomized to standard posthospital care (n equals 109) or standard care plus rehabilitation (n equals 119). At 5 years, the groups were similar on measures of symptoms, medication use, exercise capacity, and depression scores. However, rehabilitated patients reported more freedom of physical mobility (Nottingham Health Profile, P equals 0.005), perceived better health (P equals 0.03), and a perceived better overall life situation (P equals 0.02). A larger proportion of the rehabilitated patients were working at 3 years (P equals 0.02). This difference disappeared with longer follow-up (429). Patients who sustained an infarct followed by coronary bypass had greater improvement in exercise tolerance after rehabilitation (change in exercise capacity 2.8 plus or minus 1.4 metabolic equivalents) than did those having infarct alone (0.8

Downloaded from circ.ahajournals.org by on August 4, 2008

plus or minus 2, *P* less than 0.02). Improvement was sustained to 2 years (430).

In addition to benefiting a sense of well-being, there is an economic benefit that accrues from participation in cardiac rehabilitation programs. During a 3-year follow-up (mean of 21 months) after coronary events (58% of events were coronary bypass operations), per capita hospitalization charges were $739 lower for rehabilitated patients compared with nonparticipants ($1197 plus or minus $3911 versus $1936 plus or minus $5459, *P* equals 0.022) (431).

After CABG, the patient is more likely to resume sexual activity and to a greater degree than is the patient postinfarct. Anticipatory and proactive advice by the physician or surgeon on the safety of resumption of sexual activity as the patient reengages in other daily activities is beneficial (432).

In summary, cardiac rehabilitation should be offered to all eligible patients after coronary bypass surgery.

4.2.6. Emotional Dysfunction and Psychosocial Considerations

The 2 most important independent psychosocial predictors of death in a multivariate analysis of elderly patients post-CABG are a lack of social participation and religious strength (433). Social isolation is associated with increased mortality and coronary disease (434), and successful treatment may improve outcomes (435). Depression is generally poorly recognized by the cardiac specialist (421). Mood for up to 1 year after coronary bypass is correlated most strongly with mood before coronary bypass. The prevalent opinion that depression is a common result of coronary bypass is challenged by several reports (436). Half of patients who were depressed before operation were not depressed afterward, and only 9% of patients experienced new depression postoperatively. The overall prevalence of depression at 1 month and 1 year was 33%, which was similar to that in reports of patients undergoing other major operations. Some have argued that preoperative screening simply sensitizes the healthcare team and family to postoperative mood problems, rather than there being a more direct pathophysiological association of coronary bypass and depression per se. Coronary disease and psychiatric disorders are highly prevalent and frequently concurrent. Anxiety and depression are often encountered around the time of coronary bypass operation. Anxiety may intensify the autonomic manifestations of coronary disease and complicate patient care. Realization of one's mortality, physical limitations, limitations of sexual activity, survival guilt after successful operation, and development of nihilism regarding modification of risk factors play a role in recovery. Denial has adaptive value during hospitalization and can enhance care, but its persistence in the early home convalescence may be counterproductive. Clinical depression is correlated with subsequent mortality (437).

Eighteen percent of patients are depressed after major cardiac events, including coronary bypass (421). Cardiac rehabilitation has a highly beneficial effect on these patients, whether moderately or severely depressed. In a prospective but uncontrolled study of 3 months of rehabilitation on measures of depression, anxiety, hostility, somatization, mental health, energy, general health, bodily pain, functional status, well-being, and a total quality of life score, patients were improved from 20% to 57% (*P* value for the scores ranged from 0.001 to 0.004) (421).

4.2.7. Rapid Sustained Recovery After Operation

Rapid recovery and early discharge, the "fast-track" approach, for the patient post-CABG should become the standard goal of care. The shortest postoperative stays in the hospital are followed by the fewest rehospitalizations (438). There is very little evidence of a rise in morbidity, mortality, or readmission rates in systems employing fast-track protocols. Longer initial hospitalizations generally are recognized not to prevent rehospitalizations. Prevention or prompt correction of noncardiac disorders allows rapid recovery after coronary operations. Important components of the fast-track system are patient selection, patient and family education, short-acting narcotic or inhalational anesthetic agents allowing early extubation and transfer from the intensive care setting, prophylactic antiarrhythmic therapy, dietary considerations, early ambulation, early outpatient follow-up by telephone, and a dedicated fast-track coordinator (439,440).

4.2.8. Communication Between Caregivers

A primary care physician frequently refers patients who undergo CABG to a cardiologist and/or surgeon. Maintaining appropriate and timely communication between treating physicians regarding care of the patient is crucial. The primary care physician's request for referral may well be verbal but should also be documented in writing and accompanied by relevant medical information. Ideally, the primary care physician follows the patient with the other treating physicians during the perioperative course in the hospital if circumstances and geography permit. The referral physician(s) needs to provide written reports of findings and recommendations to the primary care physician, including a copy of the discharge summary from the hospital. Discharge medications that are likely to be required for the long term should be clearly identified. The decision about the degree of responsibility for postoperative care and prevention strategies needs to be made by mutual agreement among the patient, the primary care physician, the cardiologist, and the surgeon in each individual case. The primary care physician can emphasize and continue to implement secondary prevention strategies, frequently begun by the cardiologist and surgeon, since most of these strategies involve lifestyle changes or pharmacological therapies over an extended period of time.

5. SPECIAL PATIENT SUBSETS

5.1. CABG in the Elderly: Age 70 and Older

The evolution in surgical techniques and changing demographics and patient selection for CABG surgery have led to

Downloaded from circ.ahajournals.org by on August 4, 2008

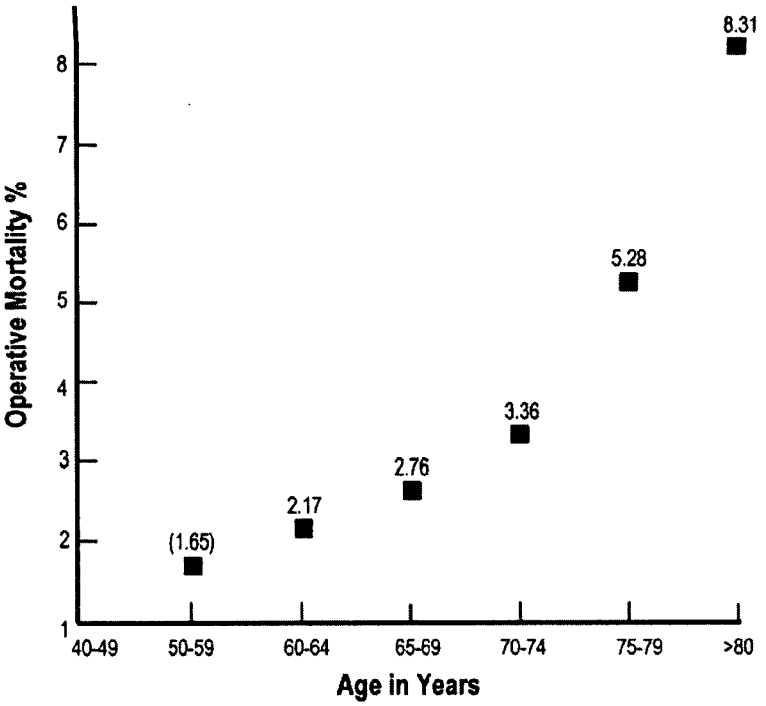

Figure 10. Operative mortality (%) for CABG in various age cohorts. Data derived from Hannan et al. Am Heart J. 1994;128:1184-91 (21).

its application in older and sicker patients with more complex disease (441). Nearly all reports during the past 10 years define "elderly" in the context of coronary surgery as age 70 years or older. However, the definition of elderly in the literature has gradually increased from 65 years or older to 80 years or older. The greatest increase in numbers has occurred in the oldest group, persons 85 years or older (442). This group has a higher incidence of left main disease, multivessel disease, LV dysfunction, and reoperation as the indication for surgery, and for many, concomitant valvular surgery. These patients generally have more comorbid conditions, including diabetes, hypertension, COPD, PVD, and renal disease. This combination of more advanced coronary disease and worse comorbidity leads to increased fatal and nonfatal complications. Higher rates of intraoperative or postoperative MI, low-output syndrome, stroke, gastrointestinal complications, wound infection, renal failure, and use of an IABP may occur (443,444). In Figure 10, operative mortality (%) is shown as a function of age. A near-linear slope increases abruptly at age 75. Similarly, in Figure 11 the OR for operative mortality is shown as a function of age (21). The effects of these factors on patient outcomes and institutional resources have significant implications for peer review, quality assurance screening, institutional reporting to external sources, and reimbursement (443).

Operative mortality in the elderly has ranged from 5% to 20% during the past 20 years for isolated CABG, averaging 8.9%. In a large study from Ontario, Canada, Ivanov et al (442) found a 34% reduction in risk-adjusted operative mortality (1982 to 1996) while confirming a time-related increase in the prevalence of older patients and an increase in the preoperative risk profile in these patients. They reported an overall mortality of less than 5% for elderly patients, with a 3% mortality for low- and medium-risk patients.

Preoperative predictors of hospital mortality and morbidity (30 days) in elderly patients include a near-linear relation to New York Heart Association (NYHA) class and/or reduced LVEF (particularly if less than 0.20). Other correlates of increased risk include increasing age; recent MI (less than 30 days), especially in the presence of unstable angina, left main disease, or 3-vessel disease; emergency or urgent coronary bypass; reoperation; reduced renal function; cerebrovascular disease; COPD; a smoking history; obesity; and female sex (21,445-452). A higher operative mortality occurs for all identified risk factors in patients aged 75 years or older than for those less than 65 years old. However, in particular, emergency surgery confers up to a 10-fold increase in risk (3.5% to 35%), urgent surgery a 3-fold increase (3.5% to 15%), hemodynamic instability a 3- to 10-fold increase, and an LVEF less than 0.20 up to a 10-fold increase (21,453,454). Predictors of postoperative low cardiac output syndrome are, in descending order of importance, LVEF less than 0.20, repeat operation, emergency operation, female sex, diabetes mellitus, age greater than 70 years, left main disease, recent MI, and/or 3-vessel disease (455). The greatest risk is in the acutely ill, elderly patient for whom the CABG operation may be the best of several high-risk options (456).

Downloaded from circ.ahajournals.org by on August 4, 2008

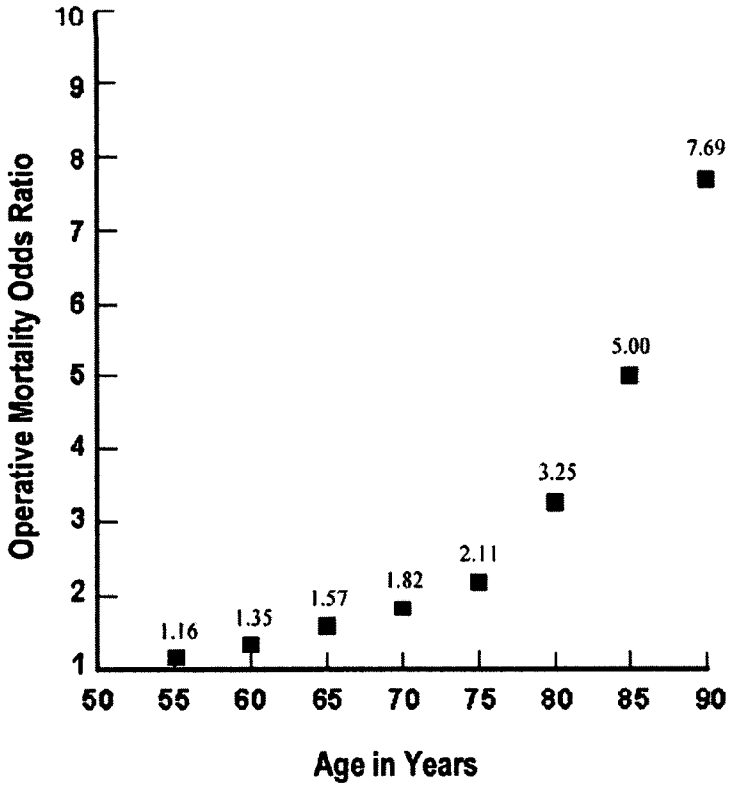

Figure 11. Operative mortality odds ratio (relative to odds for 50-year-old patients). Data derived from Hannan et al. Am Heart J. 1994;128:1184-91(21).

Operative factors that have been reported to adversely influence hospital mortality in the elderly include the use of bilateral IMA grafts, prolonged pump time and/or cross-clamp time, an increased number of grafts required, right IMA grafting, and any postoperative complication (448,449,457,458). Obesity has been identified as a risk factor for infection in patients receiving bilateral IMA grafts (457). Contrariwise, improved hospital mortality and long-term survival have been reported when the left IMA is used along with 1 or more vein grafts as opposed to vein grafting alone. Thus, use of the left IMA as a conduit appears to be a predictor of improved early and late survival (41,42,276,459). CABG without cardiopulmonary pump assistance may be advantageous in high-risk patients, particularly those with an LVEF less than 0.35 (460,461).

Postoperative atrial fibrillation is a particular problem in elderly patients undergoing CABG. Correlates of postoperative atrial fibrillation include age greater than 70 (especially age greater than 80), male sex, postoperative pulmonary complications, ventilation time greater than 24 hours, return to the intensive care unit, and use of the IABP. Atrial fibrillation contributes to a substantially prolonged hospital stay (9.3 plus or minus 19 versus 15.3 plus or minus 28 days) (351). Patients with preoperative chronic renal failure are at a particular risk, as they tend to be older and have additional comorbidity (71). Interventions to prevent atrial fibrillation are discussed in Section 4.1.5.

It should be emphasized that long-term survival and functional improvement can be achieved in the elderly patient despite severe cardiovascular disease and an urgent indication for surgery (462). The 5-year survival of such patients who recover from surgery is comparable to that of the general population matched for age, sex, and race (463,465). Preoperative variables that are correlated with poor long-term survival in elderly patients include the presence of atrial fibrillation, smoking, PVD, and poor renal function (low creatinine clearance). An unsatisfactory functional outcome has been influenced by hypertension, cerebrovascular insufficiency, and poor renal function (low creatinine clearance) (466).

Peterson et al (467) analyzed the Medicare database to assess long-term survival in patients 80 years and older and found it comparable to the general population of octogenarians. This group was hospitalized significantly longer than those aged 70 or younger (21.4 versus 14.3 days) and had a higher hospital mortality (11.5% versus 4.4%) and higher 3-year mortality (28.8% versus 18.1%). Hospital costs and charges were also higher. Similar findings are reported by others, with actuarial survival including hospital death at 80 months of 32.8% versus 37.6% for age-, sex-, and race-matched populations. These authors concluded that

Downloaded from circ.ahajournals.org by on August 4, 2008

advanced age alone should not be a contraindication to CABG if it had been determined that long-term benefits outweighed the procedural risk (465,467,468). Although hospitalization may be longer for elderly patients, physiological, psychological, and social recovery patterns through the first 6 weeks postoperatively have been reported to be similar to those of a younger age group (469). Age 70 and older is an independent risk factor for stroke after CABG, adversely affecting hospital mortality, prolonging the hospital stay, and negatively impacting late death (470).

In operations combining valve surgery and CABG, independent predictors for reduced late survival included NYHA Class IV, age greater than 70 years, male sex, decreased LVEF, extent of CAD and use of a small prosthetic valve, but not necessarily the presence of CAD per se (471-474).

In summary, the patient aged 70 years or older who may be a candidate for CABG surgery has, on average, a higher risk for mortality and morbidity from the operative procedure in a direct relation to age, LV function, extent of coronary disease, comorbid conditions, and whether or not the procedure is emergent, urgent, or a reoperation. Nonetheless, functional recovery and an improvement in quality of life may be achieved in the large majority of such patients.

The patient and physician together should explore the potential benefits of improved quality of life with the attendant risks of the procedure versus alternative therapy, taking into account baseline functional capacities and patient preferences. Age alone should not be a contraindication to CABG surgery if it is thought that long-term benefits outweigh the procedural risk (448,475-477).

5.2. CABG in Women

Early studies provided evidence that female sex was an independent risk factor for higher in-hospital mortality and morbidity than in males, but that long-term survival and functional recovery were similar to those in males undergoing CABG surgery (29,478-481). More recent studies have suggested that on average, women have a disadvantageous preoperative clinical profile that may account for much of this perceived difference. This includes the fact that women present for treatment at an older age, with poorer LV function, more frequently with unstable angina pectoris, NYHA Class IV heart failure, 3-vessel and left main disease, and more comorbid conditions including hypothyroidism, renal disease, diabetes mellitus, hypertension, and PVD (25,480-489). Based on these differences, it has been inferred that women may be under-referred or referred late for treatment and/or coronary angiography. These findings are not universal, as significant differences exist in clinical practice between institutions (481,482).

A variety of factors may account for the perception that female sex is an independent risk factor for in-hospital mortality and morbidity after CABG surgery. For example, Israeli women were reported to have a 3.2-fold higher hospital mortality than men, but women also received a higher number of SVGs, suggesting more diffuse disease. When this consideration was adjusted for, mortality was found to be similar (490). Others have argued that smaller coronary arteries in women may contribute to higher risk (26). IMA grafts have been reported to be used less often in women, possibly contributing to a higher mortality (25,486). Kurlansky et al (78) reported favorable results in 327 women with bilateral IMA grafts plus supplemental vein grafts, with a hospital mortality of 3% to 4%, low postoperative morbidity, excellent functional improvement, and enhanced long-term survival. Five-year survival of 90.5% and of 65.6% at 10 years was achieved, with 94% of patients reaching NYHA Class I and 4.5% NYHA Class II. Hammar et al (480) reported that when age and body surface area were taken into account, the relative operative risk between men and women became similar. Others have also found no differences in operative mortality, total postoperative morbidity, and ICU length of stay (491,492). Comparable findings were reported for coronary bypass surgery in black male and female patients (493).

However, analysis from the CASS registry found a higher operative mortality for women (493) as did Jaglal et al (494), even when comorbidities were adjusted for appropriately. They suggested that the excessive mortality was due to late treatment (494). Farrer et al (495) found that women had more severe symptoms with a similar severity of coronary disease as defined by angiography when compared with men, suggesting a referral bias with referral occurring later in the course of the disease. Whether these perceived biases are real and whether they are practitioner or patient related or have a biological explanation is not known. They serve as a challenge for future investigation (496).

Postoperative complications in women mirror those seen in all patients undergoing CABG surgery. These include MI, stroke, reoperation for bleeding, pulmonary insufficiency, renal insufficiency, sternal wound infection (perhaps related to obesity), CHF, rhythm other than normal sinus rhythm, and low cardiac output syndrome (25,78,490). Women appear particularly vulnerable to postoperative CHF, low cardiac output syndrome (25,29,482), and blood loss (485). Although postoperative depression is common in women and men, its occurrence in women has been reported to be more common (about 60%) and more commonly unrecognized (484). Nonetheless, at 6 months postoperatively, men and women report similar psychosocial recovery (100) (see Section 4).

In the CASS registry, although a higher operative mortality for women was found, the subsequent 15-year postoperative survival and benefits were similar to those for men. Greater absolute benefit was achieved in those with the highest risk in both male and female groups. For women, independent risk factors for poorer long-term survival included older age, prior MI, prior CABG, and diabetes mellitus (497).

Over time, changes in the clinical characteristics of women undergoing CABG mirror those of the changing characteristics of the general population. One study compared female

Downloaded from circ.ahajournals.org by on August 4, 2008

0223
09/15/08

patients operated on between 1974 and 1979 to a group receiving surgery between 1988 and 1999 and showed that operative mortality had increased from 1.3% to 5.8%. This rise was attributed to an older cohort of women, more emergency or urgent operations, an increased incidence of depressed LV function, diabetes mellitus, and more 3-vessel and left main disease, all suggesting that the female population undergoing coronary bypass surgery had changed (498). In another report, women aged 70 or older were found to be at no greater risk for operative mortality and postoperative complications than men of similar age (499).

Another study based on the STS national database examined more than 300 000 patients undergoing CABG after 1994. Women were found to have a significantly higher operative mortality for all risk factors examined even when normalized for size (body surface area). A logistic risk model was used to determine the net impact of all risk factors. The model showed that in risk-matched patients, female gender was an independent risk factor of operative mortality in low- and moderate-risk subsets but not in high-risk populations (28).

In conclusion, it appears that in-hospital mortality and morbidity and long-term survival are related more to risk factors and patient characteristics than to sex. Coronary bypass surgery should therefore not be delayed or denied to women who have the appropriate indications for revascularization.

5.3. CABG in Patients With Diabetes

Coronary artery disease is the leading cause of death among adult patients with diabetes and accounts for about 3 times as many deaths among patients with diabetes as among patients without diabetes (500). Not only is the frequency of acute MI increased in patients with diabetes (501,502) but also its treatment is more complicated than in the patients without diabetes. Patients with diabetes with acute MI, regardless of the level of control of their diabetes before hospital admission, exhibit significantly higher mortality and morbidity, with fatality rates as high as 25% in the first year after infarction in some series. Several factors contribute to this increase in mortality. The size of the infarct tends to be greater, and patients with diabetes have a greater frequency of CHF, shock, arrhythmias, and recurrent MI than do patients without diabetes. Similarly, patients with diabetes with unstable angina have a higher mortality than do patients without diabetes. A prospective study indicated a 3-month mortality of 8.6% and 1-year mortality of 16.7% in patients with diabetes versus 2.5% and 8.6%, respectively, in patients without diabetes (503).

CABG surgery in elderly patients with diabetes (age 65 or greater) has been reported to result in a reduction in mortality of 44% in CASS. The relative survival benefit of CABG versus medical therapy was comparable in patients with and without diabetes (503a). Nevertheless, a study from Sweden has indicated that patients with diabetes of all ages have a mortality rate during the 2-year period after CABG that is about twice that of patients without diabetes. Thirty-day mortality after CABG was 6.7% in patients with diabetes, and subsequent mortality between day 30 and 2 years was 7.8% compared with 3% and 3.6%, respectively, in patients without diabetes (504).

Despite increased morbidity and mortality after coronary revascularization, results from the BARI trial showed that patients with multivessel coronary disease who were being treated for diabetes at baseline had a significantly better survival after coronary revascularization with CABG than with PTCA (Figure 6) (117). In this study, patients were followed up for an average of 5.4 years. Better survival with CABG was due to reduced cardiac mortality (5.8% versus 20.6%, P equals 0.0003), which was confined to those patients receiving at least one IMA graft. Thus, although mortality after CABG surgery may be increased in patients with diabetes, CABG surgery when indicated appears to provide a better chance for survival than does medical therapy or PCI.

Large randomized trials have now reached 7 to 8 year follow-up (131,130). These updated studies generally show that 7 to 8 year survival is superior for patients with diabetes undergoing CABG compared with patients with diabetes undergoing PTCA (131,130). In the BARI trial, the protective effect of CABG was only seen in insulin-dependent patients with diabetes (505) who had an IMA graft (131). There was virtually no difference in survival among patients without diabetes.

Patients with diabetes who are candidates for renal transplantation may have a particularly strong indication for CABG surgery. Approximately 20% to 30% of these patients have significant CAD, which may be asymptomatic or unassociated with conventional cardiovascular risk factors (390,506). One study assessed the incidence of coronary disease via angiography (which was performed independently of the presence of risk factors or suggestive symptoms) in 105 consecutive dialysis patients with diabetes (390). Angiographic evidence of significant coronary disease was found in 38 (36%) patients, only 9 of whom experienced prior symptoms of angina. The degree of hypercholesterolemia, hypertension, and smoking history did not differ between those with and without documented coronary disease. Thus, noninvasive testing and, if indicated, cardiac catheterization should be performed before renal transplantation, because conventional clinical predictors of disease are unreliable and active intervention may improve patient outcomes (390,507). This approach is supported by a study that randomized 26 patients with greater than 75% stenosis in at least 1 coronary artery and relatively normal LV function to either revascularization or medical therapy with aspirin and a calcium channel blocker (506). Both the incidence of cardiovascular end points (2 of 13 versus 10 of 13) and mortality rate (0 of 13 versus 4 of 13) were lower in the revascularized patients.

5.4. CABG in Patients With Pulmonary Disease, COPD, or Respiratory Insufficiency

For many years, it has been recognized that patients undergoing cardiac surgery develop variable degrees of respirato-

Downloaded from circ.ahajournals.org by on August 4, 2008

ry insufficiency postoperatively. In these patients, higher concentrations of oxygen are required to achieve adequate arterial oxygen tension, primarily as a consequence of intrapulmonary shunting. Scattered regions of atelectasis and alveolar collapse may occur, resulting in some air spaces receiving pulmonary blood flow that are not being ventilated. Other contributing factors may occur. Impaired capillary endothelial integrity may be followed by an increase in interstitial fluid and alveolar edema. Anesthetic agents and vasodilators may affect pulmonary vasoconstriction. Other causes of gas exchange abnormalities after cardiac surgery include central effects from anesthesia and narcotics as well as CNS embolization of air or blood clots. Impairment of carbon dioxide elimination may develop from either a rise in alveolar dead space or a decrease in ventilatory drive from the effects of general anesthesia and/or narcotics. Inadequate tidal volume from neuromuscular weakness may occur. Changes in the mechanics of breathing may occur postoperatively as a result of inhalation anesthetics and/or muscle-paralyzing agents. Pain from the chest incision and thoracic or mediastinal chest tubes may result in diminished excursion of the chest and diaphragm. Obesity and rare phrenic nerve injury may also play a role (508). Postoperatively, early extubation is desirable, appears safe, and does not increase postoperative cardiac or pulmonary morbidity, especially if the total bypass time is less than 100 minutes (509,510). However, longer periods of mechanical ventilatory support postoperatively may be necessary in patients who develop acute adult respiratory distress syndrome or who have evidence of severe pulmonary insufficiency postoperatively. In such patients, ventilation with lower tidal volumes (6 mL/kg) should be considered (511).

Preoperatively, it is important to identify patients with significant restrictive or obstructive pulmonary disease. The former includes patients with pulmonary venous congestion, large pleural effusions, and a large, dilated heart compressing the lungs, all of which may result in a reduction of lung compliance. Restrictive lung disease is also found in patients with interstitial lung disease including pulmonary fibrosis, sarcoidosis, pneumoconiosis, and collagen vascular diseases. The most common cause of preoperative pulmonary dysfunction, however, is COPD. Patients with mild COPD and few or mild symptoms generally do well through cardiac surgery. However, patients with moderate to severe obstructive pulmonary disease who are undergoing coronary bypass grafting, especially those in an older age group, are at an increased risk for operative mortality and postoperative complications in relation to the severity of their degree of pulmonary dysfunction (445,512-514). Identification of these higher-risk patients is important because preoperative measures to improve respiratory function may diminish postoperative complications. These measures include the use of antibiotic therapy for lung infections, bronchodilator therapy, cessation of smoking, preoperative incentive spirometry, deep-breathing exercises, and chest physiotherapy. Such measures frequently permit patients with obstructive pulmonary disease to safely undergo cardiac surgery (512).

The parameter most commonly reported by authors in estimating the degree of pulmonary dysfunction is the forced expiratory volume in the first second (FEV_1). However, there is little consistency in the literature defining the level of abnormality for moderate to severe COPD, with values for FEV_1 ranging from less than 70% to less than 50% of the normal predicted value and/or an FEV_1 of less than 1.5 L. Others measure arterial oxygen tension and carbon dioxide tension. Any degree of hypercapnia above a normal range places the patient at least in a moderate-risk category (508,512,513), as does the need for oxygen at home before surgery. FEV_1 levels as low as 1.0 L would not necessarily disqualify a candidate for CABG surgery. Clinical evaluation of lung function is likely as important as most spirometric studies. This sentiment is reflected by Cohen et al (513), who compared 37 patients with COPD who were undergoing CABG surgery to 37 matched control patients without COPD. They defined COPD in clinical terms (i.e., age, smoking history, presence of preoperative arrhythmias, history of hospitalization for shortness of breath, and evidence of COPD on X-ray film). Those with COPD had lower values for FEV_1 (1.36 plus or minus 0.032 versus 2.33 plus or minus 0.49 L) and a lower arterial oxygen tension. This group had a significantly higher rate of preoperative atrial and ventricular arrhythmias. Postoperatively, they remained in the ICU longer, had a longer intubation period and more frequent reintubations, had more postoperative atrial and ventricular arrhythmias and complications, and remained in the hospital twice as long. By 16 months postoperatively, 5 of the COPD patients had died, with deaths related to arrhythmias. None was functionally improved after coronary bypass surgery. These investigators concluded that clinical COPD is a significant factor for morbidity and mortality, in large part due to more frequent postoperative arrhythmias. Subsequent long-term clinical benefits were significantly reduced (513). Kroenke et al (512) reported the results of 107 operations in 89 patients with severe COPD, defined as an FEV_1 less than 50% of predicted and an FEV_1 to forced vital capacity ratio of less than 70%. In this diverse group, 10 patients underwent CABG surgery. Pulmonary complications occurred postoperatively in 29% of all patients and were significantly related to the type and duration of surgery. Mortality clustered primarily around the time of CABG (5 of 10 patients) compared with only 1 death in 97 noncoronary operations. In this study, noncardiac surgery (as opposed to CABG) was accompanied by an acceptable operative risk in patients, even in the presence of severe COPD (512).

Severe, reversible, restrictive pulmonary function abnormalities, which appear not to be caused by advanced age or preexisting COPD, have been reported to follow coronary bypass surgery in the early postoperative period. In the early postoperative period, these changes may delay ventilator weaning in the first 72 hours, but full recovery is expected

Downloaded from circ.ahajournals.org by on August 4, 2008

(515). Wahl et al (515) compared pulmonary function in a group of patients older than age 70 with a group with COPD, defined as a ratio of FEV_1 to forced vital capacity of less than 70% and total lung capacity less than 80% of predicted, and a normal group in the preoperative and postoperative periods. All 3 groups demonstrated comparable decreases in FEV_1, total lung capacity, and forced vital capacity postoperatively. Partial recovery occurred by day 7 and returned to preoperative levels by 3 months (515). Similar findings were reported by Goyal et al (516) after CABG with saphenous veins, IMAs, or a combination. Others have reported more severe abnormalities of pulmonary gas exchange and pulmonary function through 72 hours postoperatively in patients receiving left IMA grafts, with normality returning by hospital discharge (517,518).

A history of COPD and greater than 2 days on a mechanical ventilator postoperatively have been reported as risk factors for nosocomial pneumonia in patients post-CABG (519) and have been documented as a risk factor for mediastinitis (520,521). Moderate to severe degrees of obstructive pulmonary disease preoperatively, whether defined by clinical or laboratory parameters, represent a significant risk factor for early mortality and/or postoperative morbidity in patients undergoing CABG. However, with careful preoperative assessment and treatment of the underlying pulmonary abnormalities, many patients may be successfully carried through the operative procedure.

5.5. CABG in Patients With End-Stage Renal Disease

Cardiovascular disease is the single best predictor of mortality in patients with end-stage renal disease (ESRD), as it accounts for almost 54% of deaths (522). The high rate of cardiac morbidity and mortality is occurring at a time when the prevalence of coronary disease is declining in the general population and is related in part to the changing nature of new patients being started on dialysis. At present, more than one third of such patients have diabetes mellitus, and the average patient age at initiation of dialysis is greater than 60 years. In addition to the foregoing, patients with ESRD usually have a number of other risk factors for cardiovascular mortality, including hypertension, LV hypertrophy, myocardial dysfunction, abnormal lipid metabolism, anemia, and increased plasma homocystine levels.

When indicated, patients on dialysis can be treated with CABG. The indications for CABG are similar to those in patients without ESRD with coronary disease. Coronary revascularization with CABG or PTCA is associated with better survival than is standard medical therapy in several specific settings. These include patients with a modest decrease in LV function, significant left main coronary disease, 3-vessel disease, and unstable angina (523). Although these patients also are at increased risk for operative morbidity and mortality, they are at even higher risk when treated with conservative medical management.

It should be noted that patients with chronic renal failure clearly differ in several respects from other patients who undergo surgical coronary revascularization. Patients with ESRD often have multiple comorbid disorders, including hypertension and diabetes mellitus, each with its own complications and associated impact on both short- and long-term survival (524). In addition, infection and sepsis have been identified as significant causes of morbidity and mortality in patients with ESRD undergoing cardiac surgical procedures (524). As a result of these factors and others such as perioperative volume and electrolyte disturbances, patients with chronic renal failure are at increased risk for complications after CABG.

Patients with ESRD have an increased risk with CABG. The Northern New England Cardiovascular Disease Study Group reported that after adjusting for known risk factors in multivariate analysis, dialysis-dependent patients with renal failure were 3.1 times more likely to die after CABG (adjusted OR 3.1, 95% confidence interval 2.1 to 4.7; P less than 0.001) (525). Dialysis-dependent patients with renal failure also had a substantially increased risk of postoperative mediastinitis (3.6% versus 1.2%) and postoperative stroke (4.3% versus 1.7%) (525). CABG surgery in patients on dialysis may be associated with an acceptable mortality, with a significant increase in the quality of life for long-term survivors.

In summary, coronary bypass grafting may be performed for selected patients with ESRD who are dialysis dependent, with increased but acceptable risks of perioperative morbidity and mortality. Early after revascularization, patients may expect relief from coronary symptoms with coincident improvement in overall functional status. However, long-term survival remains relatively limited in this patient population, suggesting a need for further investigations to establish the relative costs and benefits of revascularization in patients with dialysis-dependent ESRD.

5.6. Valve Disease

Class I

Patients undergoing CABG who have severe aortic stenosis (mean gradient greater than or equal to 50 mm Hg or Doppler velocity greater than or equal to 4 m/s) who meet the criteria for valve replacement should have concomitant aortic valve replacement. ***(Level of Evidence: B)***

Class IIa

1. **For a preoperative diagnosis of clinically significant mitral regurgitation, concomitant mitral correction at the time of coronary bypass is probably indicated.** ***(Level of Evidence: B)***
2. **In patients undergoing CABG who have moderate aortic stenosis and are at acceptable risk for aortic valve replacement (mean gradient 30 to 50 mm Hg or Doppler velocity 3 to 4 m/s) concomitant aortic valve**

Downloaded from circ.ahajournals.org by on August 4, 2008

0226
09/15/08

replacement is probably indicated. ***(Level of Evidence: B)***

Class IIb

Patients undergoing CABG who have mild aortic stenosis (mean gradient less than 30 mm Hg or Doppler velocity less than 3 m/s) may be considered candidates for aortic valve replacement if risk of the combined procedure is acceptable. ***(Level of Evidence: C)***

The coexistence of CAD and valvular disease will vary throughout the population, dependent on which disease initiates the patient's symptoms, their age, sex, and clinical risk factors. The incidence of aortic valve disease in patients undergoing CABG is much less than the incidence of CAD in patients undergoing valve replacement. In general, the incidence of CAD in patients with typical angina who are undergoing aortic valve replacement (AVR) is 40% to 50% and drops to about 25% in patients with atypical chest pain and to about 20% in those without chest pain (526-533). The incidence of CAD is generally less in patients with aortic regurgitation than aortic stenosis owing to the younger patient population presenting with aortic regurgitation (526-533). The incidence of CAD in patients with mitral stenosis is small, owing to the fact that this lesion is more frequently seen in middle-aged women.

There is a distinctive relationship between mitral regurgitation (MR) and CAD, especially when the mitral valve is structurally normal but functionally regurgitant. This MR is usually caused by ischemia. The quandary this presents is when the MR requires correction at the time of CABG. The question is easily answered if there are structural abnormalities in the mitral apparatus. Mitral repair is indicated in the majority of such circumstances, although occasional patients require valve replacement. The structurally normal mitral valve may be regurgitant due to reversible ischemia involving the papillary muscles, and the dilemma is, "When is it necessary to inspect the mitral valve for correction?" Intraoperative TEE has brought dramatic refinement to this question by providing a functional and quantitative assessment before and after CPB. When the MR is grade 1 to 2, this may decrease during anesthesia induction and/or with complete revascularization, thus eliminating the need to inspect the valve during cross-clamping of the aorta. An added finding by echocardiography or direct inspection at the time of operation is the presence of an enlarged left atrium, which generally signifies chronicity of the MR and adds justification to the consideration of mitral valve repair. This strategy is further assessed by a final post-CPB TEE in the operating room. If, under this circumstance, the MR is unacceptable, reinstitution of CPB can be performed and the MR corrected. For instance, if the MR is grade 3 to 4, it is necessary to inspect the valve and correct the mechanical lesion. It is important to stress that in this situation, it is imperative that an intraoperative TEE be performed to see whether the MR is grade 3 to 4, to assess the reparability of the valve, and to assess success of the repair. The study by Aklog and associates (534) concluded that CABG surgery alone for moderate ischemic MR leaves many patients with significant residual MR. These authors conclude that a preoperative diagnosis of moderate MR may warrant concomitant mitral annuloplasty (534).

For situations in which patients are undergoing mitral valve surgery and have "incidental" CAD and nonischemic mitral valve disease, the approach has been to perform CABG on vessels with greater than 50% stenosis at the same operation. There are far fewer data on this topic than that of AVR and CAD, but conventional wisdom has promoted this policy, and there have not been reports of significant increases in operative mortality.

The discussion of combined procedures revolves around overall operative risk, which is dependent on several variables. The most notable of these are age greater than 70 years, female sex, advanced NYHA class, poor LV function, and multiple valve procedures (535). There is also a difference in early and late mortality when the valve lesion is aortic versus mitral and when the mitral lesion is ischemic. The simple addition of MR to a coronary bypass without valve correction increases the operative mortality to 3% to 5%. The operative mortality of rheumatic mitral valve disease and CAD varies from 3% to 20% (536). The addition of a valve operation to CABG is also associated with a substantial increase in the risk of stroke (536a).

The results of combined aortic valve and coronary disease have led to the recommendation to graft obstructed vessels (greater than or equal to 50%) when an AVR is performed. The operative mortality for patients undergoing AVR who have ungrafted CAD approaches 10%, while those patients having AVR and concomitant CABG for CAD have an operative mortality approaching that of AVR alone (537). It is generally accepted that the risk of adding CABG to a valve replacement or repair will increase the operative mortality over that of an isolated valve procedure. The additional variables of age greater than 70 or 80 years and poor LVEF will further increase this risk.

Another aspect of this combined condition is the patient with prior CABG who now requires a valve replacement or repair. There is inconclusive evidence that the reoperative risk of late AVR after previous CABG is significantly increased. Sundt et al (538) stated that the operative risk for AVR alone was 6.3%, whereas the risk of AVR after previous CABG was 7.4%. Odell et al (539) found the risk of reoperative AVR with prior CABG to be 12%. A report from the same institution identified an operative risk of 3.7% (11 of 297) for isolated AVR (540). The discrepancy may be due to sample size, in that the article by Sundt et al reviewed 52 patients, whereas Odell et al reported on 145 patients undergoing reoperation for AVR with prior CABG.

5.7. Reoperation

Patients who have undergone CABG may present with recurrent ischemic syndromes and be considered for reoper-

Downloaded from circ.ahajournals.org by on August 4, 2008

0227
09/15/08

ation. The voluntary STS National Database has reported an incidence of reoperation of 8.6% to 10.4% in isolated bypass operations since 1987, and in centers experienced with reoperations, the percentage of isolated bypass operations constituting reoperations may be 20% to 25%. Reoperative candidates represent a distinct subgroup of bypass surgery patients. Segments of myocardium may be supplied by patent arterial grafts (at risk for damage during reoperation) or by atherosclerotic vein grafts. Vein graft atherosclerosis is a pathology that is different from native-vessel CAD and it is more prone to cause embolization and thrombosis. In addition, reoperative candidates are older and often have far advanced coronary and noncoronary atherosclerosis. Left ventricular function is commonly abnormal, and conduits to perform bypass grafts may be lacking (541).

The mortality rate for reoperation is greater than that for primary surgery, although in experienced centers that risk differential has narrowed with time. Advanced age, abnormal LV function, number of atherosclerotic vein grafts, the number of previous bypass operations, and emergency status are specific variables that have been consistently associated with an increased in-hospital risk associated with reoperation. Emergency operation, in particular, substantially increases the risk of reoperation. Third and fourth bypass operations are increasing in frequency and have all the difficulties associated with a second operation, only more so. They have been associated with an increased mortality rate, an increased risk of hospital complications, and increased cost (541).

However, despite the difficulties of reoperation, it is often the best treatment strategy for many patients with recurrent ischemic syndromes. No randomized studies comparing treatment options for patients with previous bypass surgery exist. However, an observational study of patients receiving coronary angiograms after bypass surgery has shown that for patients with late (greater than or equal to 5 years after operation) stenoses in vein grafts, there is a high risk of subsequent cardiac events and a relatively high risk of death. A subsequent observational comparative study showed that reoperation improved the survival rate and symptom status of patients with late vein graft stenoses, particularly if an atherosclerotic vein graft subtended the LAD coronary artery. Further studies have identified a positive stress test as a factor that incrementally defines a group of patients at high risk without repeat surgery. Percutaneous procedures have often been effective in the treatment of patients with native coronary stenoses but have been particularly ineffective in the treatment of atherosclerotic vein graft stenoses. These considerations combined with late survival rates after reoperation of 90% to 95% at 5 years, and more than 75% at 10 years, indicate that reoperation can be a sound form of treatment for patients with severe symptoms or survival jeopardy (541).

As the impact of vein graft atherosclerosis on graft failure was appreciated in the early 1980s, it appeared as though the need for coronary reoperation might become overwhelming, but a number of factors decrease the reoperation rate. One is the use of arterial grafts. Despite the lack of randomized data observational studies clearly indicate that use of the left IMA to LAD graft decreases reoperation rate. Studies also indicate that the strategy of bilateral IMA grafting may further decrease the reoperation rate. Second, vein graft failure may be delayed by pharmacological treatment. Early vein graft patency rates are clearly improved by perioperative treatment with platelet inhibitors, and the use of postoperative statin therapy decreases late vein graft failure rate and the incidence of late clinical events. Finally, the availability of percutaneous treatments may further delay the need for reoperation (541).

5.8. Concomitant PVD

The coexistence of CAD and PVD is well known. It is estimated that the prevalence of serious, angiographic CAD ranges from 37% to 78% in patients undergoing operation for PVD (542). CAD is the leading cause of both early and late mortality in patients undergoing peripheral vascular reconstruction (543). MI is responsible for about half of all postoperative deaths in patients undergoing abdominal aortic aneurysm resection (544,545), extracranial revascularization (199,546), or lower-extremity revascularization (545,547). Long-term survival after successful vascular reconstruction is limited by the high incidence of subsequent cardiac death (548). On the other hand, the presence of PVD is a strong, independent predictor of long-term mortality in patients with stable chronic angina (549). After successful myocardial revascularization, patients with PVD are at substantially increased risk for in-hospital (37) and long-term (550) mortality.

The importance of preoperative cardiac evaluation was demonstrated by Hertzer et al (543) in a study of 1000 patients with PVD: abdominal aortic aneurysm, cerebrovascular disease, or lower-extremity ischemia. All 1000 patients underwent coronary angiography. Severe, surgically correctable CAD was found in 25% of the patients; 34% of the patients suspected to have CAD on clinical grounds were found to have severe, surgically correctable CAD; 14% of the patients not suspected to have CAD were found to have severe, surgically correctable CAD. The early postoperative mortality rate after the peripheral vascular procedures was lower in patients who had preliminary CABG compared with those who did not. The long-term beneficial effect of preliminary CABG in patients undergoing peripheral vascular reconstruction was reported by Eagle et al (549) in their retrospective cohort analysis of 1834 patients with combined CAD and PVD. Nine hundred eighty-six patients received CABG and 848 patients were treated medically. In a mean follow-up of 10.4 years, 1100 deaths occurred and 80% were due to cardiovascular causes. The group treated with surgical coronary revascularization had significant survival benefits at 4, 8, 12, and 16 years compared with patients treated with medical therapy alone. Subgroup analysis suggested that the long-term survival benefits of surgical coronary

Downloaded from circ.ahajournals.org by on August 4, 2008

revascularization were particularly seen in patients with 3-vessel CAD and depressed LVEFs.

The predictive value of PVD for short- and long-term clinical outcomes of patients receiving CABG was also examined by the Northern New England Cardiovascular Disease Study Group (37,550). In-hospital mortality rates with CABG in patients with PVDs were 7.7%, a 2.4-fold higher incidence than in patients without PVD (3.2%). After adjusting for higher comorbidity scores associated with patients with PVD, patients with PVD were 73% more likely to die in hospital after CABG. The excess risk of in-hospital mortality associated with PVD was particularly notable in patients with lower-extremity occlusive disease (adjusted OR 2.03). The presence of cerebrovascular disease had a small but nonsignificant effect on CABG-related in-hospital deaths (adjusted OR 1.13).

Excess mortality rates in patients with PVD were due primarily to an increased incidence of heart failure and dysrhythmias rather than cerebrovascular accidents or peripheral arterial complications. The difference in mortality rate was also apparent at long-term follow-up. Five-year mortality after CABG was substantially higher in patients with PVD than in those without PVD, with a crude hazard ratio of 2.77 and an adjusted hazard ratio of 2.01 after multivariate adjustment for comorbid conditions. Significantly elevated adjusted hazard ratios occurred in patients with overt cerebrovascular disease, clinical and subclinical lower-extremity occlusive disease, abdominal aortic aneurysm, and combined PVDs. Asymptomatic carotid bruit or stenosis conferred a small, nonsignificant increased adjusted hazard ratio of 1.47. In summary, the presence of clinical and subclinical PVD is a strong predictor of increased in-hospital and long-term mortality rate in patients undergoing CABG.

5.9. Poor LV Function

See Section 9.2.5 for recommendations.

LV function is an important predictor of early and late mortality after coronary artery surgery. LV dysfunction is associated with an increased risk of perioperative and long-term mortality in patients undergoing coronary bypass surgery compared with patients with normal LV function. Both low EF and clinical heart failure are predictive of higher operative mortality rates with CABG (551). In 6630 patients who underwent isolated CABG surgery in the CASS registry, the average operative mortality was 2.3%, ranging from 1.9% in patients with an EF greater than or equal to 0.50 to 6.7% in patients with an EF less than 0.19 (552). An operative mortality of 6.6% in patients with an EF less than 0.35 in comparison with 2.6% in patients with an EF greater than 0.50 was reported (553). Compared with patients with an EF of 0.40 or higher, patients whose EF was less than 0.20 or between 0.20 and 0.39 had 3.4 and 1.5 times higher perioperative mortality rates, respectively (17). Reports of perioperative mortality rate varied widely, ranging from about 5% in excellent centers in patients of a younger age, with fewer symptoms, and having no comorbid conditions, to greater than 30% in patients who were older, with severe ventricular dysfunction, and having several comorbid conditions (551). A trend toward lower operative mortality rates in recent years compared with those in early years has been reported, perhaps due to better myocardial protection techniques and perioperative management in the contemporary period.

Analysis of patients with an EF less than 0.35 from the CASS registry showed 5-year survival rates of 73%, 70%, and 62% in patients with an EF from 0.31 to 0.35, 0.26 to 0.30, and less than 0.25, respectively (554). A comparison between surgically treated and medically treated groups revealed the greatest surgical benefit in patients with an EF of 0.25 or less. The medically treated patients had a 5-year survival rate of 43% compared with 63% for those treated with coronary bypass surgery. A comparison study of 5824 patients who underwent medical or surgical therapy for ischemic heart disease in the Duke University Cardiovascular Database showed that patients with the worst LV function (EF less than 0.35) had the greatest 10-year survival benefit from bypass surgery (46% versus 27%). Patients with an EF of 0.35 to 0.50 had a 10-year survival rate of 62% in the surgical group versus 50% in the medical group (87). Patients with severe LV dysfunction have increased perioperative and long-term mortality compared with patients with normal LV function. However, the beneficial effects of myocardial revascularization in patients with ischemic heart disease and severe LV dysfunction are clearly evident when compared with medically treated patients in terms of symptom relief, exercise tolerance, and long-term survival (87,551,555,556). Coronary artery bypass graft surgery is recommended in patients with severe multivessel disease and poor ventricular function but with a large amount of viable myocardium. Patient selection is crucial for achieving the beneficial effects of myocardial revascularization in this subset of patients and is discussed in Section 9.

5.10. Transplantation Patients

Cardiac transplantation is an accepted treatment for end-stage heart failure, with greater than 30 000 cardiac transplantations performed worldwide to date (557). Allograft CAD is the leading cause of death after the first year of transplantation (558-560). This type of occlusive CAD is diffuse, often rapidly progressive, and affects a substantial number of heart transplant recipients. The incidence of angiographic transplant vasculopathy is estimated at 40% to 45% at 3 to 5 years after transplantation with a yearly attrition rate of 15% to 20% (561,562). Angina pectoris is rarely the presenting symptom in patients with allograft CAD owing to the lack of afferent autonomic innervation, although partial reinnervation of the allograft can occur. Silent MI, heart failure due to loss of allograft function, and sudden cardiac death are the common signs of cardiac allograft vasculopathy (561). Analysis of coronary angiograms of affected cardiac allografts has revealed unique morphological features consisting of diffuse, concentric narrowing

Downloaded from circ.ahajournals.org by on August 4, 2008

0229
09/15/08

in middle and distal vessels with distal vessel obliteration and a paucity of calcium deposition (563). The underlying pathophysiology of allograft vasculopathy is largely unknown, but it is likely a common final pathway of a constellation of immunologic and nonimmunologic injuries, namely chronic rejection, cytomegalovirus infection, hyperlipidemia, and older donor age (563-565). Treatment of hyperlipidemia with pravastatin (566) or weekly LDL apheresis (567) has been reported to lower the incidence of coronary vasculopathy or even lead to regression. Currently, retransplantation is the only definitive therapy for advanced allograft vasculopathy. Good results have been reported with PCI and directional coronary atherectomy in selected patients with discrete and proximal coronary focal lesions (568-569a). In general, coronary bypass surgery is not an option because of the diffuse type of coronary disease in patients with cardiac allograft vasculopathy. Isolated cases of successful coronary bypass grafting have been reported (570,571). In a report of 5 patients who underwent CABG for cardiac allograft vasculopathy, 3 patients died during the perioperative period and 1 died at 50 days.

It is well known that ESRD is associated with an increased risk of CAD (572). The safety and efficacy of coronary bypass grafting were reported in 31 renal transplant patients who underwent isolated coronary bypass surgery (573). Perioperative mortality was 3.2%, and no renal allograft function was impaired. Overall, 1- and 5-year survival rates for patients undergoing open heart surgery were 88% and 85%, respectively (573). The safety and efficacy of CABG were also reported in a small series of 3 patients with transplanted livers, with no deaths or hepatic decompensation and good improvement of cardiac symptoms (574). (See Section 5.5. on ESRD.)

5.11. CABG in Acute Coronary Syndromes

Class I

If clinical circumstances permit, clopidogrel should be withheld for 5 days before performance of CABG surgery. *(Level of Evidence: B)*

The acute coronary syndromes represent a continuum from severe angina to acute MI. Various classifications are based on the presence or absence of Q waves associated with evidence for myocardial necrosis, the elevation or depression of ST segments on the electrocardiogram, and clinical definitions based on the pattern of angina. Historically, a clinical definition encompassing progressive, rest, and postinfarction angina and Q-wave and non–Q-wave MI has been used to examine the effects of surgery. More recent nomenclature defines the spectrum of acute coronary syndromes from unstable angina to non–ST-segment elevation MI (NSTEMI) to ST-segment elevation MI (STEMI). Where appropriate, we use the new classification in this document, recognizing, however, that many of the cited trials categorized the patient subgroups according to the older nomenclature.

The effectiveness of CABG for unstable angina was first demonstrated in a randomized Veterans Administration trial comparing medical therapy with CABG initiated in 1976 (575). Although there was no overall difference in survival between medically and surgically treated patients, an improvement in survival with CABG occurred in patients in the lowest tertile of EF (0.3 to 0.58) at 3, 5, and 8 years of follow-up (105), in those with 3-vessel disease (576), and in those with LV dysfunction presenting with electrocardiographic changes (577). At 5 years of follow-up, surgically treated patients had less angina and improved exercise tolerance and required fewer antianginal medications than did the medically treated patients (110). It is difficult to interpret the results of this study because surgical and medical therapies have both evolved substantially, including the routine use of modern techniques for myocardial preservation, arterial bypass conduits, aspirin, fibrinolytics, and PCI.

There have been no randomized trials specifically comparing CABG and PCI in patients with unstable angina and multivessel CAD. The BARI trial prespecified a comparison subgroup based on the severity of angina. In this trial, 7% of patients had unstable angina or NSTEMI. There was no difference in 5-year overall survival for these patients treated with either CABG (88.8%) or PTCA (86.1%, *P* equals NS) (117). However, there was an increased cardiac mortality in patients treated with PTCA (8.8%) compared with CABG (4.9%), and this difference was entirely due to a difference in outcomes in treated patients with diabetes (129).

Table 17. Factors Associated With Adverse Outcome During Coronary Artery Bypass Grafting for Unstable Angina

Factor (Reference)	Relative Risk of Mortality (Range)
Clinical	
Recent MI: less than 24 h (777), less than 48 h (585), less than 30 d (451)	2.1-1.8
Female (451,582,584,777)	1.4-1.7
Age (451,452,584,779)	2.9-5.3*
IDDM (779)	8.3†
Angiographic/hemodynamic	
No. of diseased vessels (582,584)	1.9-2.3 (EF 0.20-0.39)
LV dysfunction (451,452,584)	5.9-10.7 (EF less than 0.20)
Hypotension (452,777)	6.5-7.8
Surgical	
Aortic cross-clamp time (582,779)	2.25‡
Urgent surgery (584,777)	1.8-1.9
Bypass time (779)	...
IABP support (779)	4.1

MI indicates myocardial infarction; IDDM, insulin-dependent diabetes mellitus; LV, left ventricular; IABP, intra-aortic balloon pump; and EF, ejection fraction.

*Age greater than 70 years.

†Relative risk for perioperative MI.

‡Relative risk of major adverse outcome greater than or equal to 100 versus less than 100 minutes.

Downloaded from circ.ahajournals.org by on August 4, 2008

In contrast, EAST included a large proportion (60%) of randomized patients with Canadian Cardiovascular Society Class IV angina, and there was no difference in mortality at 3 years (119). Similarly, 59% of enrollees in RITA had rest angina, and this study demonstrated no significant differences in death or MI at 2.5 years of follow-up (126). There was a particularly high incidence of unstable angina (83%) in the small ERACI trial (133). These patients had mostly complex lesions (50% type B2 and 13% type C), which are associated with greater angioplasty complications (578). However, in-hospital mortality was higher with CABG (4.6% versus 1.5%), and 3-year survival and freedom from STEMI were similar for both forms of revascularization (133).

No studies have addressed the important subset of patients with unstable angina after prior CABG. The culprit lesion in these patients is often located in a vein graft, where both angioplasty and reoperative CABG have less success (412).

Several early studies performed before 1990 demonstrated an increased surgical mortality ranging from 4.6% to 7.3% in patients with unstable angina (414,579-581). More studies have confirmed this finding (582,583). In the series of Louagie et al (582), 474 patients admitted with prolonged rest angina and requiring surgery during the same hospitalization had an operative mortality of 6.8% and a perioperative MI rate of 7.2%, and 19% required placement of an IABP. A study examining early revascularization versus conservative therapy for patients with NSTEMI had a much higher 30-day surgical mortality (12%) in patients undergoing early CABG compared with those managed conservatively (5%) (418).

In patients with post-infarct angina, a higher mortality has been observed, particularly with early operation after STEMI (409,579,584). Braxton et al (585) compared 116 patients operated on within 6 weeks of MI with 255 patients without prior MI. Mortality was highest (50%) in 6 patients with STEMI undergoing surgery less than 48 hours after infarction versus 7.7% in 52 patients undergoing surgery 3 to 42 days after infarction and versus 2% to 3% when CABG was performed even later and in patients without prior infarction. Factors associated with adverse outcomes during CABG for unstable angina are listed in Table 17.

A new issue that has arisen concerns the risk of CABG in patients with acute coronary syndrome treated with new and more potent antithrombotic and antiplatelet therapies. Several studies have demonstrated a greater risk for postoperative hemorrhage in patients treated with low-molecular-weight heparin (586), abciximab (587), and clopidogrel (588). It is important to understand the pharmacokinetics of these agents to reduce the risk. For instance, no increased bleeding was observed when the short-acting glycoprotein IIb/IIIa inhibitor eptifibatide was discontinued at least 2 hours before bypass (589), when platelet transfusions were appropriately administered after abciximab (590), and when clopidogrel was withheld for 5 days before surgery (588). In some instances, the need for urgent surgery supercedes the risk.

The use of CABG for primary reperfusion during STEMI has largely been superseded by fibrinolysis and primary PTCA. Early coronary bypass for acute infarction may be appropriate in patients with residual ongoing ischemia despite nonsurgical therapy and if other conditions warrant urgent surgery, including left main or 3-vessel disease, associated valve disease, mechanical complications, and anatomy unsuitable for other forms of therapy.

In conclusion, CABG offers a survival advantage compared with medical therapy in patients with unstable angina and LV dysfunction, particularly in those with 3-vessel disease. Currently, there is no convincing survival advantage for surgery over PTCA in patients with unstable angina suitable for treatment with either technique. However, the risk of CABG in patients with unstable angina, postinfarction angina, early after non-STEMI, and during acute MI is increased several fold relative to patients with stable angina, although the risk is not necessarily higher than that of medical therapy for these patients.

6. IMPACT OF EVOLVING TECHNOLOGY

6.1. Less-Invasive CABG

Patients presenting for CABG are older, have more comorbid conditions, and as a group have a higher predicted risk of mortality than their historical predecessors. Despite these trends, clinical outcomes after CABG have continued to improve (591,592).

Before 1995, the vast majority of CABG procedures used a midline sternotomy incision, CPB, and global cardioplegic arrest. Cardiopulmonary bypass has adverse effects on many organ systems and elicits a systemic inflammatory response. Some have sought to minimize the invasiveness of CABG through the elimination of CPB or through the use of smaller incisions or both.

Coronary artery bypass graft surgery on a beating heart without CPB was first reported by Kolessov in 1967, who was technically challenged by the motion of the heart, and access to the posterior surface of the heart was not possible (10). The technique was largely abandoned in the United States after the refinement of CPB. However, CABG on a beating heart was still practiced in several countries, where much experience was accumulated (593,594). These procedures were primarily reserved for patients needing LAD or right coronary artery (RCA) bypass because techniques for safe access to the lateral and posterior wall arteries had not developed.

Single LAD bypass on the beating heart through a small anterolateral thoracotomy (MID-CAB) was reintroduced in the mid-1990s (595-597). Target coronary artery stabilization was initially achieved with pharmacologically induced bradycardia or intermittent temporary asystole, with small bolus infusions of adenosine. Early angiographic anastomotic patency rates were inferior to those achieved with conventional CPB-CABG and prompted the development of

Downloaded from circ.ahajournals.org by on August 4, 2008

various styles of mechanical stabilizers to limit target artery motion. Patency rates improved with experience and with the use of mechanical stabilization (598).

Surgeons uncommonly are referred patients with single-vessel LAD disease, but the results of MID-CAB fostered interest in the development of techniques for multivessel OPCAB. Building on the experience of Benetti and Bufolo, surgeons developed methods to safely access lateral wall and posterior wall vessels. With mechanical coronary artery stabilizers, devices for clearing the anastomotic field of blood, intracoronary shunts, and techniques and devices for cardiac positioning, many centers were able to report sizeable series in which the large majority of CABG procedures were achieved without CPB (599-602).

Several retrospective studies have suggested that OPCAB may reduce morbidity and/or mortality. Nearly all reports have demonstrated reductions in the need for transfusion of blood products, shorter ICU stays, and shorter postoperative lengths of stay. Some of these studies have also suggested that hospital costs are reduced (603-605).

Hernandez et al (606) reported on the experience of the Northern New England Cardiovascular Disease Study Group comparing 1741 OPCAB and 6126 contemporaneous CPB patients. The groups differed somewhat in preoperative risk factors, but their predicted risk of mortality was the same. They found no differences in crude rates of mortality, stroke, mediastinitis, or return to the operating room for bleeding. OPCAB patients had a reduced need for IABP support, less atrial fibrillation, and shorter median postoperative lengths of stay.

Magee et al (607) reviewed all multivessel CABG procedures from 2 large institutions from January 1998 through July 2000. They entered 8449 patients (1983 OPCAB, 6466 CPB) into a multivariate logistic regression analysis to evaluate the impact of CPB on mortality, independent of other risk factors known to affect mortality. They also used propensity scoring to computer match pairs of OPCAB and CPB patients in an attempt to remove selection bias from the analysis. CPB was associated with increased mortality compared with OPCAB by univariate analysis (CPB 3.5%, OPCAB 1.8 %) even though the OPCAB group had a higher predicted mortality. CPB was associated with increased mortality by multiple regression analysis (OR 1.79, 95% confidence interval 1.24 to 2.67). The combined computer-matched groups based on OPCAB-selection propensity score also demonstrated an increased risk of mortality for CPB (OR 1.9, 95% confidence interval 1.2 to 3.1).

Plomondon et al (608) reviewed CABG-only procedures from the Veterans Affairs Continuous Improvement in Cardiac Surgery Program records from October 1997 through March 1999. Nine centers were identified that had completed at least 8% of their CABG procedures as OPCAB and were designated as study hospitals. OPCAB patients (n equals 680) from these hospitals were then compared with CPB patients (n equals 1733) for mortality or morbidity. Predicted mortality was higher in the OPCAB group (OPCAB 4.4%; CPB 3.9%; *P* equals 0.0022), as was predicted morbidity (OPCAB 13.2%; CPB 11.9%; *P* equals 0.0008). OPCAB patients experienced lower mortality (OPCAB 2.7%; CPB 4.0%) and lower morbidity (OPCAB 8.8%; CPB 14%; *P* equals 0.001). Multivariable OR for OPCAB versus CPB groups, after risk adjustment for patient risk factors, were computed. For mortality, the OR for OPCAB was 0.56 (95% confidence interval, 0.32 to 0.93, *P* equals 0.033), and for morbidity the OR was 0.52 (95% confidence interval, 0.38 to 0.70, *P* less than 0.0001). Observed-to expected ratios for mortality and morbidity were less than 1.0 for OPCAB patients and more than 1.0 for CPB patients. The authors concluded that in centers experienced in beating heart coronary bypass, an off-pump approach for CABG was associated with lower risk-adjusted morbidity and mortality.

Cleveland et al (609) reported on the largest multicenter report to date. They retrieved data from the STS National Cardiac Surgery Database from a 2-year period of time (January 1998 through December 1999) and identified 126 centers experienced in OPCAB. There were 11 717 (9.9%) OPCAB patients and 106 423 (90.1%) CPB patients. The OPCAB patients were older, were more likely female, and were less likely to be diabetic than the CPB subjects. The OPCAB group also had more patients with preexisting COPD, dialysis-dependent renal failure, and cerebrovascular disease than the CPB group. The CPB patients were more likely to have 3-vessel disease, and more of them were in need of urgent or emergency CABG. Predicted mortality was similar (OPCAB 2.88%; CPB 2.87%). The observed risk-adjusted mortality in the OPCAB group was 2.31%, and that of the CPB group was 2.93% (*P* less than 0.0001). The risk-adjusted rate of major morbidity in the OPCAB group was 10.62% compared with 14.15% in the CPB group (*P* less than 0.0001). When complications were examined individually, the OPCAB group had fewer strokes (OPCAB 1.25%; CPB 1.99%; *P* less than 0.001), less postoperative renal failure (OPCAB 3.85%; CPB 4.26%; *P* equals 0.036), and fewer patients with postoperative cardiac arrest (OPCAB 1.42%; CPB 1.74%; *P* equals 0.010), and fewer patients returned to the operating room for bleeding (OPCAB 2.07%; CPB 2.80%; *P* less than 0.001). Additionally, in patients with pre-existing COPD or cerebrovascular disease, OPCAB patients were less likely to require prolonged mechanical ventilation or to have stroke or coma, respectively.

Three randomized, prospective trials have been reported comparing OPCAB and CPB CABG. None of these trials were large enough to demonstrate any differences in operative mortality or the occurrence of postoperative stroke.

Angelini et al (610) pooled data from 2 separate randomized trials. OPCAB patients were shown to have reduced morbidity (e.g., transfusion, chest infection). At midterm follow-up there were no differences between groups with regard to cardiac death or cardiac events.

van Dijk et al (611) randomized relatively low-risk patients (n equals 281) to OPCAB or CPB CABG. Completeness of revascularization was equivalent between groups. OPCAB patients required fewer intraoperative

Downloaded from circ.ahajournals.org by on August 4, 2008

transfusions and had lower levels of cardiac-specific enzyme release. At 1 month, no differences were noted in rates of cardiac death or cardiac-related events.

Puskas et al (612) randomized 201 patients to OPCAB or CPB CABG. No patients were excluded on the basis of coronary artery anatomy, LV dysfunction, or any comorbidity. Intended target vessels were identified and recorded preoperatively before randomization. OPCAB patients required fewer transfusions, had less release of cardiac-specific enzymes, had shorter times to extubation, had shorter ICU and postoperative lengths of stay, and had lower hospital costs. Levels of revascularization were identical between groups.

Patients with significant comorbidity have been reported to have been revascularized by OPCAB techniques. The elderly, patients with prior CABG, patients with left main CAD, and those with impaired myocardial, renal, or pulmonary function have all been reported to have been safely and effectively approached without CPB.

Larger randomized trials will be necessary to delineate which patients benefit from the avoidance of CPB and what the magnitude of that benefit actually is.

The third emerging technique in less-invasive cardiac surgery is the closed-chest, port-access, video-assisted CABG operation developed at Stanford, Calif (613). CPB and cardioplegia of a globally arrested heart are integral parts of this technology. Vascular access for CPB is achieved via the femoral artery and vein. A triple-lumen catheter with an inflatable balloon at its distal end is used to achieve endovascular aortic occlusion, cardioplegia delivery, and LV decompression. With CPB and cardioplegic arrest, CABG can be performed on a still and decompressed heart, through several small ports and with the aid of a videoscope. In comparison with the MID-CAB approach, the port-access technique allows access to different areas of the heart, thus facilitating more complete revascularization, and the motionless heart allows for accurate anastomosis. The proposed advantage of this approach compared with conventional CABG is the avoidance of median sternotomy, with the resultant diminished incisional pain and faster recovery. The potential morbidity of the port-access technique stems from the multiple port sites, limited thoracotomy, and groin dissection for femoral-femoral bypass. The short- and long-term safety, benefits, and efficacy of the minimally invasive port-access approach must be compared with the conventional operation in an appropriately controlled clinical trial. As in any new technology, vigorous scientific scrutiny must be applied before any conclusions can be made.

6.1.1. Robotics

Investigational work continues in the development of robotic coronary bypass. Closed-chest multiarterial bypass on the beating heart would offer the maximum benefit via the least invasive approach. CPB and thoracotomy would be avoided, and the durability of arterial CABG would be preserved.

Boyd et al (614) described 4 levels of robotically assisted coronary bypass currently being investigated.

1. Voice-activated robotic control of an intrathoracic camera placed through a port and used for video-assisted manual endoscopic harvesting of the IMA with standard endoscopic instruments. A manual beating heart anastomosis is then completed through a small thoracotomy.
2. Video-assisted port-access telerobotic conduit harvesting, in which the surgeon works from a computer-enhanced remote console to harvest the IMA with port-access telemanipulators (robotic arms). A manual beating heart anastomosis is then completed through a small thoracotomy.
3. Computer-assisted endoscopic coronary artery anastomoses in which the conduit is harvested manually via standard sternotomy and the coronary anastomosis is constructed on the arrested or beating heart from the computer-enhanced master console through telemanipulators passed via ports.
4. Totally endoscopic coronary bypass during which conduit harvesting and preparation, target coronary artery identification and preparation, vascular control, and the anastomosis are all accomplished from the computer-enhanced console via port-access telemanipulators without any chest incision.

Successful application of all 4 of these strategies has been reported from specialized centers (615-618). The major obstacle to a totally endoscopic CABG has been the technical difficulty in the construction of an accurate anastomosis. Considerable effort is under way to develop technology for a facilitated anastomotic device, perhaps avoiding the need for a sutured anastomosis. Robotically assisted coronary artery bypass must be considered a work in progress at this time.

6.2. Arterial and Alternate Conduits

Class I

In every patient undergoing CABG, the left IMA should be given primary consideration for revascularization of the LAD artery. ***(Level of Evidence: B)***

The benefits of bypass surgery are related to patent bypass grafts, and short- and long-term graft patency is associated with cardiac morbidity and mortality. The most commonly used bypass grafts have been the in situ IMA and segments of greater saphenous vein (SVG) used as aorta-to-coronary grafts. By the early 1980s, serial angiographic studies of vein grafts made it apparent that SVGs could develop intrinsic pathological changes, intimal fibroplasia and vein graft atherosclerosis, that were progressive and compromised long-term graft patency rates. Late vein graft patency rates ranged from 70% to 80% at 5 postoperative years to 40-60% at 10 postoperative years. Fortunately, similar serial studies

Downloaded from circ.ahajournals.org by on August 4, 2008

0233
09/15/08

showed that IMA grafts had early patency rates of greater than 90%, but more importantly, they showed that late attrition of IMA grafts is extremely uncommon, resulting in a late patency rate of in situ IMA grafts of 90% or more at 10 postoperative years. The clinical importance of the left IMA-to-LAD graft was emphasized by a long-term follow-up study that compared patients with left IMA-LAD grafts and supplemental vein grafts to patients receiving only vein grafts. The patients receiving left IMA-to-LAD grafts had a better survival rate, fewer reoperations, and fewer cardiac events at a 10-year follow-up.

In the modern era, it can be expected that vein graft patency rates will be improved over the earlier studies. Randomized trials have shown that perioperative treatment of patients with platelet inhibitors improves bypass graft patency rates at 1 postoperative year. Prospective angiographic studies from the BARI trial documented an 87% 1-year vein graft patency rate compared with 98% for IMA grafts. Furthermore, aggressive treatment with statins appears to decrease vein graft attrition rate. However, although the interventions have decreased vein graft failure, it has not been eliminated. The prospective study of SVG patency rates noted a 66% patency rate at 10 postoperative years.

If 1 IMA graft is good, might 2 be better? The use of the right IMA in addition to the left IMA (bilateral IMA, or BIMA, grafting) for bypass grafting has been employed as a surgical strategy since the early years of bypass surgery. Despite the apparent logic of using 2 grafts anticipated to have excellent long-term patency rates, evidence that BIMA grafting (or any other extension of arterial grafting) provides incremental clinical benefit over the left IMA-to-LAD graft in associated vein graft strategy (single IMA, or SIMA, grafting) has been difficult to document for a variety of reasons. First, there are no randomized studies concerning this issue. Second, too few institutions have used BIMA grafting to provide enough patients to allow detailed analysis. Third, survival rates after SIMA grafting are favorable for the first postoperative decade, meaning that particularly long-term follow-up studies are necessary to allow any differences to become apparent. Fourth, patient selection can confound the analysis of outcomes. In general, studies of BIMA grafting have excluded patients undergoing emergency operation and those with previous bypass surgery and have included decreased numbers of patients with diabetes. However, there are now several nonrandomized, risk-adjusted, comparative studies that show improved long-term outcomes for patients receiving BIMA grafts in terms of fewer reoperations and improved late survival rates. BIMA grafting has not become a routine strategy even for elective patients for multiple reasons, including increased operative difficulty, increased operative time, and the risk of wound complications. Most studies have shown an increase in the risk of wound complications with BIMA grafting, usually in patients with diabetes. The use of techniques for skeletonizing the IMAs during preparation, thus minimizing the decrement in sternal blood supply, may decrease the incidence of sternal complications, but even modern studies of BIMA grafting have shown an increased risk of wound complications in obese diabetic patients.

The use of the radial artery as a conduit for coronary bypass grafting was first reported by Carpentier et al (619) in 1973. Its use was quickly abandoned when occlusion rates up to 30% were reported (620,621). Interest in its use was revived in 1989 when radial artery grafts were found to be patent in patients who had undergone their coronary artery surgery 13 to 18 years earlier. The radial artery is a thick muscular artery with an average diameter of 2.5 mm and an average length of 20 cm. It is prone to spasm when mechanically stimulated, and perioperative calcium channel blockers or long-acting nitrates are often used to reduce this complication. The technique of minimal manipulation and en bloc dissection of the radial artery with its surrounding satellite veins and fatty tissue is thought to account for the superior results in experiences with radial artery grafting. Brodman et al (622) reported a 95% 12-week patency rate in 175 patients receiving 229 radial artery grafts (54 patients had bilateral radial artery grafts). Perioperative MI and mortality rates were similar to those of conventional bypass surgery. There was no reported hand ischemia, wound hematoma, or infection. A 2.6% incidence of transient forearm dysesthesia, which resolved over 1 day to 4 weeks after surgery, was reported. Acar et al (623) reported an 84% 5-year radial artery graft patency rate in 100 consecutive patients receiving the radial artery as a conduit for coronary revascularization. In the same group of patients, the left IMA graft patency rate was 90% at 5 years. Thus, the radial artery appears to be a safe and reliable arterial conduit for coronary revascularization on the basis of these early clinical experiences.

Use of the in situ right gastroepiploic artery as a conduit for CABG was first reported in 1987 (624,625). This artery can be harvested by extending the median sternotomy incision toward the umbilicus and dissecting the artery along the greater curvature of the stomach. A pedicle length of 15 cm or more can be achieved by mobilizing the artery to the origin of the gastroduodenal artery. It can be grafted to the right or circumflex coronary artery by routing it in a retrogastric fashion or to the LAD in an antegastric fashion. Early graft patency ranged from 90% to 100% (626-628), but long-term results have not been published. The inferior epigastric artery free graft has been used for CABG since 1990 (629,630). This artery can be harvested by retracting the rectus muscle via a paramedian incision. A length of 6 to 16 cm can be dissected from its origin from the external iliac artery (631). Short-term patency rates of up to 98% have been reported (632). Long-term results are not available.

Cryopreserved homologous SVGs and glutaraldehyde-treated homologous umbilical veins grafts have been used for clinical aortocoronary bypass surgery (633,634). Graft patency was reported to be only 50% at 3 to 13 months. These grafts should not be used unless other conduits are

Downloaded from circ.ahajournals.org by on August 4, 2008

unavailable. Similarly, the bovine IMA has been used, again with about 50% 1-year patency (635,636). Synthetic grafts that have been used for aortocoronary bypass include Dacron grafts and polytetrafluoroethylene grafts. Only a few successful cases of Dacron graft use have been reported, and these were in patients in whom the graft was used as an interposition between the ascending aorta and the proximal end of a coronary artery with resultant high flow (637-639). The patency of polytetrafluoroethylene grafts is also limited and has been reported to be about 60% at 1 year (640,641).

6.3. Percutaneous Technology

Technological improvements have had a great impact on PTCA and have included new medications and devices that have reduced both the acute and long-term complications of percutaneous coronary interventions. The most significant medication advance has been the introduction of new platelet inhibitors, which have reduced the incidence of MI and death during angioplasty and related interventions (642).

In the area of devices, intracoronary stents have reduced complications, including the need for emergency surgery, as well as the need for repeated interventions due to restenosis (643,644). New refinements in stent design and adjunctive pharmacological therapy are further improving patient outcomes after stenting (645). Directional coronary atherectomy has also been shown to reduce restenosis compared with conventional PTCA, but its role relative to stents is not yet clear (646). Several new devices, such as the transluminal extraction catheter (InterVentional Technologies, Inc., San Diego, CA) and the Angioget thrombectomy catheter (Possis Medical, Inc., Minneapolis, MN), that remove thrombus before intervention either have been approved for use or are undergoing investigation and may reduce complications in some high-risk subsets of patients. Rotational atherectomy or rotational ablation has expanded the types of lesions (eg, calcified or long lesions) that can be treated without surgery (647).

Restenosis remains the greatest weakness of PTCA and is being addressed by mechanical solutions such as stents and directional atherectomy, which improve the intimal lumen diameter, and by pharmacological interventions aimed at preventing intimal hyperplasia. Promising approaches included in this latter category are medications such as probucol and folate (648-650), gene therapy, and local radiation therapy (651-653). Finally, the balance between bypass surgery and PCI is being further altered as the promise of new technology offered by drug-eluting stents is realized (654).

After CABG surgery, failure of the SVG is a major cause of recurrent cardiac ischemia. Angiographic studies have shown that 16% to 31% of SVGs fail within 1 year (655-658), and within 10 years, about half of all vein grafts are totally occluded or have severe atherosclerotic disease (74,659,660). It is estimated that vein graft failure is responsible for recurrent angina at an annual rate of 4% to 9% in patients after aortocoronary artery bypass grafting (661-663). In these patients, repeated CABG surgery is a satisfactory option. However, in comparison with initial bypass surgery, reoperation is technically more challenging and is associated with higher perioperative morbidity and mortality as well as less symptomatic relief (664-666). As alternatives to repeated bypass surgery, various percutaneous techniques have been developed to treat stenotic vein grafts. These techniques include conventional balloon angioplasty and the use of newer interventional devices such as coronary stents and directional coronary atherectomy.

In general, the results of angioplasty in SVGs are less favorable than in native vessels, with less procedural success and a higher rate of restenosis. Several factors influence the clinical outcome of the procedure: age of the graft, location of the stenosis within the graft, and the discrete (versus diffuse) morphological features of the atherosclerotic plaques (667-670). In a randomized comparison with angioplasty, directional coronary atherectomy was associated with a higher initial success rate and fewer repeated target-vessel interventions at 6 months but more periprocedural complications, most notably distal embolization and NSTEMI (671,672).

Intracoronary stents are now commonly used in the management of SVG stenosis. A multicenter, prospective, randomized trial compared the effects of stent placement with those of balloon angioplasty on clinical and angiographic outcomes in patients with obstructive disease of SVGs (673). Compared with the balloon angioplasty group, stenting of vein graft lesions resulted in a higher rate of procedural efficacy (92% versus 69%) and a greater increase in luminal diameter immediately after the procedure (1.92 versus 1.21 mm) and at 6 months (0.85 versus 0.54 mm). The 6-month outcome in terms of freedom from death, MI, repeat bypass surgery, or revascularization of the targeted vessel was significantly better in the stent group (73% versus 58%). Although the difference in the rate of restenosis between the stent and angioplasty groups did not achieve statistical significance, it appears that stent placement has certain advantages over conventional balloon angioplasty in the initial and short-term angiographic and clinical outcomes. The use of a balloon-occlusion and aspiration device has been shown to reduce the risk of adverse cardiovascular events during SVG interventions by protecting the coronary circulation from distal embolization of atherosclerotic debris (674). More operator-friendly filter-type devices are under investigation and will likely become routine adjuncts for such procedures.

With the increasing use of MID-CAB for left IMA-to-LAD grafting, a combined strategy of MID-CAB and either balloon angioplasty or stent placement ("hybrid revascularization") to achieve complete revascularization in patients with 2-vessel disease has been used in some situations. PTCA is performed on the second diseased vessel, which has included the right coronary artery, the left circumflex artery, and the left main coronary artery. The reverse order

Downloaded from circ.ahajournals.org by on August 4, 2008

0235
09/15/08

of performing PTCA first with subsequent MID-CAB for the left IMA-to-LAD revascularization has also been described (675). The hybrid approach of MID-CAB and percutaneous intervention provides complete revascularization through limited incisions without CPB. It also provides a useful management modality for isolated patients who are at high risk for either procedure alone. This approach highlights the potential complementary role of surgery and PTCA in the management of CAD. However, long-term outcome data for patients undergoing hybrid procedures are not yet available. Also, if coronary stenting is performed, then aspirin and clopidogrel are indicated for at least 30 days, which may affect the timing of coronary surgery. Thus, the theoretical benefits of combining procedures must be matched by scientific proof of efficacy before this strategy is likely to become commonplace.

6.4. Transmyocardial Laser Revascularization

Class IIa

Transmyocardial surgical laser revascularization, either alone or in combination with CABG, is reasonable in patients with angina refractory to medical therapy who are not candidates for PCI or surgical revascularization. ***(Level of Evidence: A)***

Intracavitary arterial blood in the LV is only millimeters away from ischemic areas of myocardium. Indeed, communicating channels between the cavity and the myocardium occur in reptilian hearts and in fetal hearts during the first 7 weeks of gestation until the coronary arterial system develops. This network of communicating channels between the heart chambers and the coronary arteries, the myocardial sinusoids, the arterial-luminal and venous-luminal connections, were described in a study by Wearn et al in 1933 (676). Early attempts to use these connections to supply the ischemic myocardium included implantation of the left IMA directly into the heart muscle (677) and direct-needle acupuncture to the ischemic myocardium to create communicating channels (678,679). Sen and colleagues (678,679) used direct acupuncture and found that these acupuncture channels were protective from acute infarction after ligation of the LAD. These channels appeared to be open and endothelialized at 8 weeks but appeared to close within several months due to fibrosis and scarring secondary to local tissue injury. This technique was abandoned with the arrival of aortocoronary artery bypass surgery in the late 1960s.

Use of the carbon dioxide laser for transmyocardial revascularization was attempted in the early 1980s by Mirhoseini and coworkers (680,681). A high-energy laser beam was used to create channels from the epicardial to the endocardial surface of an arrested or beating heart, thus allowing oxygenated blood from the LV to perfuse the ischemic myocardium. Brisk bleeding from the channels due to ventricular perforation could be easily controlled with light epicardial pressure. It was postulated that a high-energy laser beam would minimize local tissue injury and prevent premature fibrotic closure of the newly created channels and thus lead to improved channel patency (682). Long-term channel patency on histological examination has been reported in animal experiments and in sporadic clinical case reports (682-684). The principal utility of transmyocardial laser revascularization (TMLR) is directed toward patients with severe angina pectoris refractory to medical therapy and who are unsuitable for surgical revascularization, PCI or heart transplantation. These patients often have diffuse small-vessel disease and are not appropriate candidates for another PCI or CABG. The use of TMLR for the management of cardiac allograft vasculopathy has also been reported (685,686).

The results of a multicenter trial with TMLR as the sole therapy for 200 patients with refractory, end-stage CAD and documented reversible ischemia was reported by Horvath and colleagues (687). The perioperative mortality rate was 9%. Postprocedure angina class according to the Canadian angina classification was significantly decreased from their preoperative status at 3, 6, and 12 months of follow-up. Hospital admissions for angina were decreased from an average of 2.5 admissions in the year before treatment to an average of 0.4 admissions in the year after treatment. The number of perfusion defects in the treated LV free wall was also significantly decreased as assessed by radionuclide perfusion scan or positron emission tomographic scan performed after TMLR. A multicenter randomized, prospective study comparing TMLR with continued medical management demonstrated improved event-free survival in 160 patients with symptomatic, end-stage CAD. In the TMLR group, 72% of patients improved by at least 2 angina classes, while 69% of patients in the medical therapy group had no change of angina class; the remaining 31% experienced greater angina. Survival free of death, unstable angina, or class IV angina at 6 months was 73% for the TMLR group versus 12% in the medical management group. Quality of life indexes also improved in the TMLR group.

Five prospective, controlled, randomized trials have been reported (689-693). In each study, TMLR patients demonstrated a statistically significant improvement in angina compared with patients treated with medical therapy alone. None of the trials demonstrated a significant survival benefit, and only 1 study found a significant improvement in myocardial perfusion (692). One of the studies (689) concluded that TMLR "cannot be advocated." This trial from the United Kingdom was the only one of the randomized studies that was not a multicenter study. Their recommendation came in spite of finding a statistically significant (P less than 0.001) improvement in angina for TMLR patients compared with patients receiving medical therapy without TMLR.

Subsequent studies have supported the initial findings of these early reports. Compared with medical therapy, there appears to be consistent and sustained improvement in angina class for at least the first year after TMLR (694-700). Thereafter, the beneficial effects of TMLR decline some-

Downloaded from circ.ahajournals.org by on August 4, 2008

what (694,695,699), but Horvath et al (694), in a follow-up study to the work cited above, reported that long-term efficacy commonly persists for 5 years. As experience accumulates, it appears that operative mortality is generally less than 5% (696,701,702). The most significant predictors of operative mortality are unstable angina (703) and compromised LV function (699).

7. INSTITUTIONAL AND OPERATOR COMPETENCE

7.1. Volume Considerations

Owing to the availability of hospital and physician-specific mortality data and because of the perceived economies of scale in consolidating complex medical procedures into regional centers, considerable attention has been directed to relating outcome after CABG to the number of procedures performed. Before 1986, administrative data sets were proposed as a means of risk adjustment to compare outcomes between hospitals of high and low volume (704,705). These studies found a relationship between mortality after CABG and the volume of procedures performed annually. A cutoff at about 200 cases defined high- and low-volume institutions. High-volume institutions were determined to have superior results. The ability of administrative data sets to accurately stratify risk has since been questioned, particularly because of their inability to distinguish preoperative comorbidity data from postprocedure complications data (706-708).

Since 1986, in response to these criticisms, primary cardiac surgical data sets have appeared with sufficient power to address this question. Hannan et al (709) reported that in New York State, after adjusting for case mix, the high-volume institutions that performed greater than 223 cases annually experienced significantly lower mortality than did institutions performing fewer than 223 cases annually, with a relative risk of 0.74 (0.56 to 0.94, 95% confidence interval). This same relationship was true for individual surgeon volumes, with high-volume surgeons performing more and low-volume surgeons performing fewer than 116 CABG procedures annually. These cutoff points were determined arbitrarily by being above or below the state median, based on data from only 1 year.

The relationship between in-hospital mortality rate and surgical volume was again explored in 1991, when the cutoff for institutional volume was defined at 200 cases annually, and the relative risk, while still significant, was reduced to 0.84 (0.66 to 1.07, 95% confidence interval) (710). This report represented data collected over 3 years (1989 to 1992). In addition to showing the protective effect of high-volume institutions, the study also showed considerable variation, particularly among the low-volume centers. A further analysis of this patient population revealed that a significant portion of the observed improvement found in the overall risk-adjusted mortality rates in New York State was a disproportionate improvement experienced by the low-volume institutions compared with the high-volume institutions. Hannan et al (710) postulated that this was due in part to the out-migration of older, low-volume surgeons and the in-migration of younger, better-trained surgeons. It is also of interest that the relationship between individual surgeon volume and outcome reported in 1989 and 1991 had disappeared.

The Department of Veterans Affairs Hospitals reported on 24 394 patients operated on between 1987 and 1992 (711). While there appeared to be a significant relationship between volume and mortality rate among the 43 hospitals examined, when adjusted for case mix the relationship disappeared. Again, low-volume hospitals had a higher variation in mortality rates compared with the high-volume institutions. This variation in outcome led the Department of Veterans Affairs to routinely review low-volume institutions (fewer than 100 cases annually).

A report of the STS National Cardiac Database reviewed 124793 patients operated on by more than 1200 surgeons in more than 600 institutions. Only in institutions performing fewer than 100 cases annually (n equals 18) was the observed mortality rate of 5.0% significantly higher than the expected rate of 3.0% (2.9% to 3.2%, 95% confidence interval) (712).

Dudley et al (713) reviewed the literature linking high and low volumes to better and worse outcomes for a variety of procedures including CABG. By relying on the highest-quality studies, they were able to assign ORs for adjusted in-hospital mortality comparing high-volume hospitals and low-volume hospitals (fewer than 500 cases annually). By applying this model to the California Office of Statewide Health Planning and Development Database, they projected that there were between 124 and 372 potentially avoidable deaths in the state of California in 1997. The authors cautioned against drawing too firm a conclusion from these findings because of the inherent limitations of observational data, the possibility of inadequate risk adjustment, and the absence of a direct cause and effect relationship between volume and outcome.

Birkmeyer et al (714) reviewed Medicare claims data for 6 cardiovascular and 8 cancer-related procedures. Although they found that a volume/outcome effect was seen in all 14 procedures studied, the degree of difference in adjusted in-hospital and 30-day mortality between very-low-volume (fewer than 230 cases annually) and very-high-volume hospitals (more than 849 cases annually) ranged from a high of 12% in pancreatic resections to a low of 0.2% for carotid endarterectomies. They found that the range of adjusted mortality rates for CABG between very-low- and very-high-volume hospitals was 1.3%, which suggests that the relationship was modest at best.

The question of whether high-volume institutions performed significantly better than did moderate-volume institutions was addressed in a study from Canada. The Adult Cardiac Care Network of Ontario suggested that concentrating CABG into high-volume regional centers has explained

Downloaded from circ.ahajournals.org by on August 4, 2008

0237
09/15/08

their low observed mortality rate and the lack of variation between centers (715). This observation was not confirmed in the STS report, as Clark (712) found no protective relationship in high-volume institutions (greater than 900 cases/y).

Criticism of these reports revolves primarily around the adequacy of case-mix adjustment and the limitations of observational studies. Sowden et al (716) performed a meta-analysis of studies relating volume to outcome and found that the stronger the relationship between volume and outcome, the less case mix was accounted for. They postulated that owing to the observational nature of these studies, confounding accounted for most of the difference between high and low volume, and as confounding was reduced by improved risk stratification, the volume-outcome relationship disappeared. Sowden et al (716) also found that the volume-outcome relationship diminished over time, suggesting that low-volume institutions had "improved" faster than had high-volume institutions.

In summary, studies suggest that survival after CABG is negatively affected when carried out in institutions that perform less than a threshold number of cases annually. Similar conclusions have been drawn regarding individual surgeon volumes. In states where reporting of outcomes is an accepted practice (e.g., New York State), the relationship between low volumes at either an institutional or individual level seems to have diminished over time. This observation strengthens the argument for outcome tracking and supports a posture of close monitoring of institutions or individuals that perform less than 100 cases annually. It must be remembered that these same studies also found a wide variation in risk-adjusted mortality rates in low-volume situations; ie, some institutions and practitioners maintained excellent outcomes despite relatively low volumes. Therefore, credentialing policies based on conclusions drawn from these data must be made with caution.

7.2. Report Cards and Quality Improvement

Mortality rates after CABG have declined since the 1987 release by the Health Care Financing Administration of hospital-specific mortality data. The Northern New England Cardiovascular Disease Study Group reported a 24% decline in regional mortality from 1987 to 1993 (13). Hannan et al (717) reported that the actual mortality rate in New York State declined from 3.52% in 1989 to 2.78% in 1992 while the risk-adjusted rate decreased from 4.17% to 2.45% during the same period. The STS National Cardiac Surgical Database reported that the risk-adjusted mortality rate for CABG declined from 3.76% to 3.50% between 1990 and 1994 (16).

There are numerous potential explanations for this reduction in mortality after CABG. Some authors suggest that the feedback of outcome data associated with either an organized or implicit effort at quality improvement has been principally responsible for this decline. O'Connor et al (13) reported that a combination of regular feedback of mortality data, associated with open discussion and visitation between competing cardiac surgical programs in Maine, New Hampshire, and Vermont, was directly responsible for the 24% reduction in mortality observed there. Hannan et al (717) reported that the simple fact that outcomes were tracked and reported back to institutions led implicitly to improvement efforts that accounted for the New York State decline in mortality rate. Grover et al (718) reported on a program of data feedback and regular audit of programs by members of the Audit Committee of the Veterans Affairs Cardiac Surgery Consultants Committee that led to a decrease in observed versus risk-adjusted mortality rates within the Veterans Administration cardiac surgical system. Omoigui et al (719), a group from the Cleveland Clinic, suggested that the reduction in mortality noted in New York State was caused by an out-migration of high-risk patients due to the increased scrutiny provoked by public release of mortality data. Despite this criticism, Hannan et al (717) found no consistent bias against selecting high-risk patients in the state of New York. Ghali et al (720) suggested that the reduction seen in both northern New England and New York State would have happened regardless of quality improvement efforts, as similar improvement was found in Massachusetts where there was neither a statewide, organized improvement effort nor dissemination of mortality data. Peterson et al (721) examined Medicare data on both the total amount of improvement and the ultimate risk-adjusted mortality rate and found that New York State and northern New England showed both the lowest overall mortality rates as well as the greatest improvements of any other state or region in the country.

Although it appears clear that outcome tracking has resulted in fewer deaths after CABG, Chassin (722) would suggest that it is the public dissemination of this information that has been responsible for driving that improvement. While the 1987 Health Care Financing Administration report of CABG mortality data received widespread media attention, most newspapers focused on outlier hospitals and thus provided little guidance to consumers (723). Peterson et al (721) concluded that reporting of outcomes, whether voluntary and anonymous (northern New England) or mandatory and public (New York State), coupled with initiatives in quality improvement is indeed effective in improving mortality rates after CABG.

Besides driving improvement efforts, many suggested that public reporting of mortality data would initiate market forces that would drive patients to high-volume "centers of excellence." Yet, when clinicians and patients in Pennsylvania (724,725) and clinicians in New York State (726) were asked to assess how much the statewide reporting of outcome data influenced their referral practices, surprisingly few admitted that these efforts had any effect at all (724,726). Shahian (727) found that in the State of Massachusetts, patients preferred hospital reputation, traditional referral patterns and geographic proximity over published outcomes as determinants for selecting a cardiac sur-

Downloaded from circ.ahajournals.org by on August 4, 2008

gical provider. Finlayson (728) studied a Veterans Administration population and found that patients anticipating high-risk surgical procedures would accept a 2-fold to 6-fold increase risk of mortality to receive their care close to home.

An excellent review of the impact of outcomes reporting on cardiac surgery has been provided by Shahian et al (729). Outcome reporting in the form of risk-adjusted mortality rates after CABG has been effective in reducing mortality rates nationwide. While distortion of data (gaming) and out-migration of patients have been reported, it is doubtful that these practices have had a meaningful effect on this improvement. However, public release of hospital and physician-specific mortality rates has not been shown to drive this improvement and has failed to effectively guide consumers or alter clinicians' referral practices.

7.3. Hospital Environment

The context within which coronary surgery is performed will ultimately influence the outcome experienced by patients. Because of the highly technical nature of the procedure and the narrow clinical margin of the patient population, strategies to ensure consistent care have evolved. These strategies include establishing specialized cardiac surgical centers (heart hospitals), forming multidisciplinary clinical teams within hospitals, and creating and implementing clinical pathways, care maps, algorithms, and protocols.

Appropriately implemented clinical guidelines have been shown to improve the processes of clinical care in 90% of cases and show measurable improvement of outcome in 20% of cases (730). Successful application of clinical guidelines require they be accompanied by unambiguous statement of purpose, that clinicians for whom they are intended have some role in their creation or implementation, and that forcing functions, such as clinical pathways, algorithms, or protocols, be tied to the guidelines (731,732).

Whereas clinical practice guidelines describe an ideal treatment strategy for a particular disease process, clinical pathways (a.k.a. critical pathways, care maps) represent the optimal sequence of timing of interventions for a particular diagnosis or procedure. Well-designed clinical pathways ensure care is delivered as prescribed by a practice guideline while optimizing resource utilization, minimizing chance of error, and allowing for the reinvention of these standards within the context of local culture. They are typically created for patient populations that are large in number, relatively homogeneous in appearance, and consume large amounts of resources and have thus been found ideal for the CABG population (732,733).

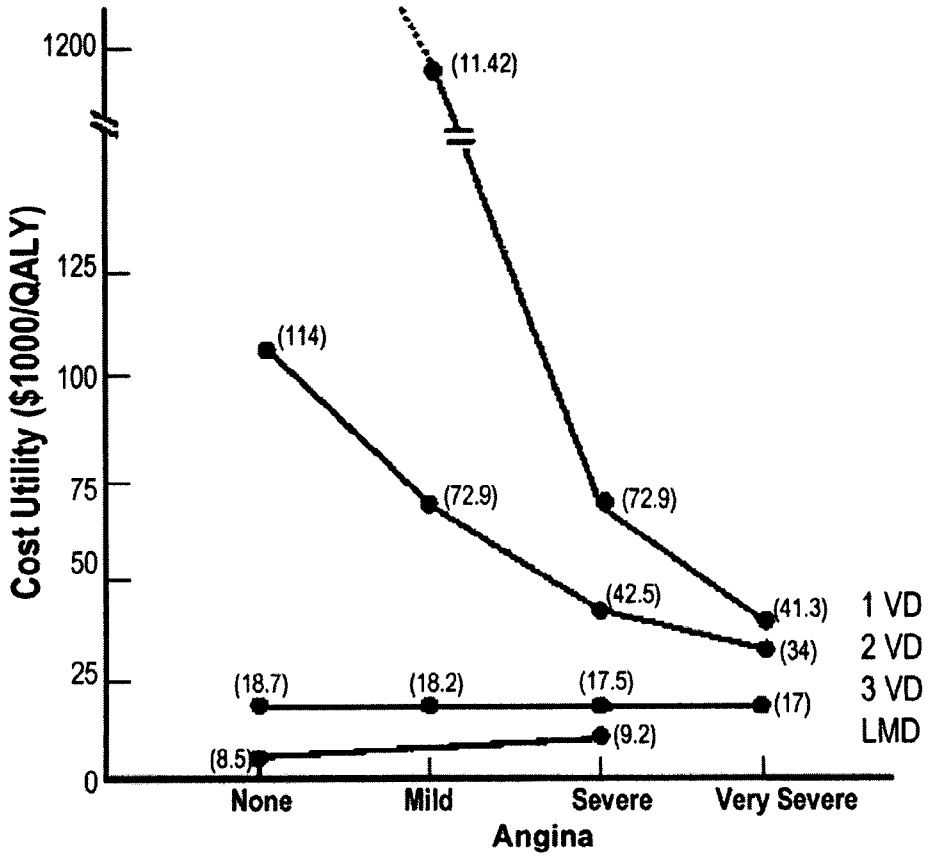

Figure 12. Cost utility. VD = vessel disease; LMD = left main disease; QALY=quality-adjusted life-year. Modified with permission from Elsevier Science Inc. (Kupersmith et al. Prog Cardiovas Dis. 1995;37:307-56) (734).

Table 18. Cost per Quality-Adjusted Life-Year ($/QALY) of Revascularization Compared With Medical Therapy*

CABG for left main stenosis, with or without angina	9000
CABG for 3VD with or without angina	18 000
CABG for 2VD with severe angina and LAD stenosis	22 000
CABG for 2VD with severe angina, no LAD disease	61 000
CABG for 2VD, no angina, with LAD stenosis	27 000
CABG for 2VD, no angina, no LAD disease	680 000
CABG for 1VD, severe angina	73 000
PTCA for 1VD, severe angina	9000
PTCA for LAD stenosis, mild angina	92 000

CABG indicates coronary artery bypass graft: 1, 2, or 3VD, 1-, 2-, or 3-vessel disease; LAD, left anterior descending coronary artery; and PTCA, percutaneous transluminal coronary angioplasty.

*Adjusted to 1993 dollars from multiple sources in a review by Kupersmith et al. Prog Cardiovas Dis. 1995;37:307-56 (734).

8. ECONOMIC ISSUES

8.1. Cost-Effectiveness of CABG

CABG represents a major investment for society, with an initial hospital cost of around $30 000 applied to more than 300 000 patients annually in the United States alone (around 10 billion dollars) (124). It is most appropriate to consider the cost of CABG surgery compared with other medical treatment modalities with regard to cost-effectiveness. Definitive data for such a comparison are sparse, and multiple assumptions must be made. The most reasonable system of analysis appears to be an estimation of the dollars spent per quality-adjusted life-year gained ($/QALY). In general, a cost-effectiveness of $20 000 to $40 000/QALY is consistent with other medical programs funded by society, such as hemodialysis and treatment of hypertension. A cost of less than $20 000/QALY would be considered particularly cost-effective, whereas a cost greater than $60 000/QALY would be considered expensive (734).

A widely quoted analysis of the cost-effectiveness of CABG surgery was compiled by Weinstein and Stason (735) in 1982 utilizing data gathered from the then-available randomized trials comparing medical therapy with coronary artery bypass. The cost of coronary bypass is relatively constant, whether it is conducted for left main disease or for single-vessel disease. Cost-effectiveness is excellent when the procedure is applied to patient subgroups for which the benefit in terms of survival or relief of symptoms compared with medical therapy is great (as it would be, for example, in a patient with severe angina and triple-vessel disease). The cost-effectiveness of CABG becomes inordinately poor, however, when the benefit in terms of survival is marginal and there are few symptoms in the preoperative patient. These conclusions are depicted in Figure 12, and examples are presented in Table 18. Cost-effectiveness for coronary bypass in patients with left main disease is exceptionally good at $9000/QALY. It is similarly quite attractive in patients with 3-vessel disease, at $18 000/QALY. If one considers the cost-effectiveness of coronary bypass in 2-vessel disease, Weinstein and Stason found that the presence or absence of LAD disease was very important. Because CABG surgery is particularly effective in relieving angina, its cost-effectiveness, even in patients with single-vessel disease, is not prohibitive if that patient has severe angina. In the patient without angina or with only mild angina, however, the cost of coronary bypass per QALY was prohibitive in this analysis, exceeding $100 000 for patients with 2-vessel or 1-vessel disease.

It is not surprising that coronary bypass surgery is cost-effective in exactly those groups of patients in whom survival and/or symptomatic benefit is demonstrable. Most important, within these subsets the cost-effectiveness of coronary bypass compares favorably with other generally accepted medical therapies.

8.2. Cost Comparison With Angioplasty

The cost-effectiveness of angioplasty is dependent on the preangioplasty symptoms of the patient in the same way that CABG surgery is so dependent, particularly in subgroups in whom revascularization cannot be shown to have a survival benefit compared with medical therapy (i.e., in single-vessel disease). Because it relieves angina, angioplasty for single-vessel-disease patients with severe angina is estimated to have a cost-effectiveness of $9000/QALY. In patients with only mild angina, however, angioplasty in the setting of LAD single-vessel disease is estimated to have a poor cost-effectiveness of $92 000/QALY (736).

A direct comparison of the cost of angioplasty and coronary bypass surgery for selected patients with multivessel disease (i.e., those patients for whom either therapeutic modality was considered appropriate) has been made in the randomized trials of angioplasty versus CABG. In general, the cost analyses of randomized trials have revealed that the initial cost of angioplasty is about 50% to 65% of the initial cost of bypass surgery. The incremental cost of repeated procedures during the follow-up period has led to a cumulative cost of angioplasty that approaches the cumulative cost of bypass surgery at 3 years. The EAST found that the 3-year inpatient cost of angioplasty was 94% of that of bypass surgery (135). The RITA trial, which included a large number of patients with single-vessel disease, found that the 2-year cumulative cost of angioplasty was 80% of the cost of coronary bypass (136). The BARI trial conducted a prospectively designed analysis of the comparative cost of the 2 procedures from a subgroup of the participating centers, comprising a total of 934 of the 1829 patients enrolled (124). The mean initial hospital cost of angioplasty was 65% of that of surgery, but after 5 years the cumulative cost of initial surgical therapy was only $2700 more than the cost of initial angioplasty (around a 5% difference). Because the surgical

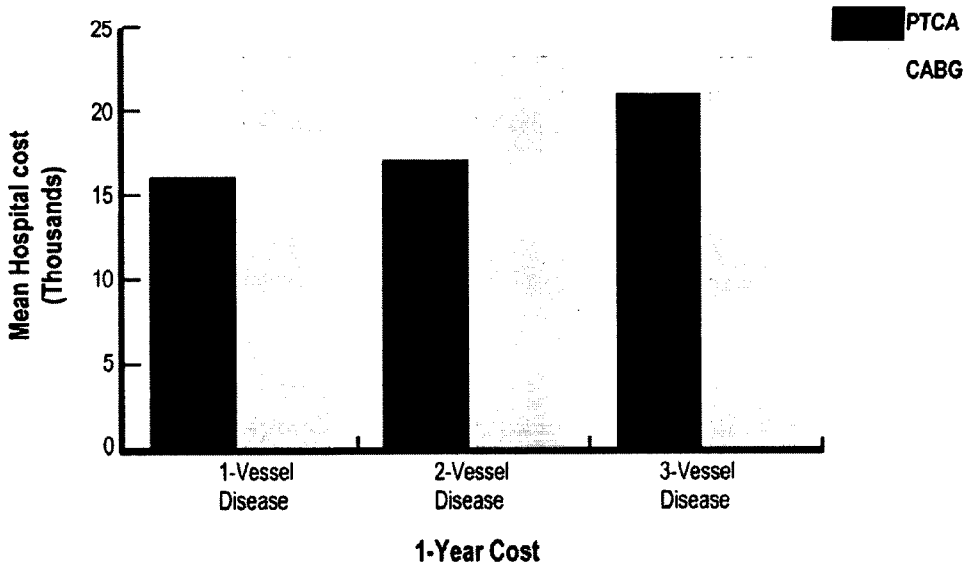

Figure 13. Percentage of 1-year costs for PTCA and CABG. PTCA indicates percutaneous transluminal coronary angioplasty; CABG, coronary artery bypass graft. Reprinted with permission from the Society of Thoracic Surgeons (Mark. Ann Thorac Surg 1996;61:S12-5) (737).

cohort had a higher overall 5-year survival, the cost of this survival benefit could be calculated. It was found to be $26 000/y of survival benefit for surgical therapy of 2- and 3-vessel disease (in patients for whom either angioplasty or surgery was considered appropriate initial therapy). As considered in the previous section, this incremental cost for double- and triple-vessel disease is within the range of costs for generally accepted therapies. It is notable that this cost of incremental benefit does not consider the benefit of coronary bypass in terms of relief of angina during the follow-up interval, which was demonstrated in each of these 3 trials (BARI, EAST, and RITA). If this factor were included, the cost-effectiveness of CABG for incremental benefit in these selected patients with multivessel disease ($/QALY) would be less than $26 000.

Previous considerations of both patient benefit and cost-effectiveness have suggested that angioplasty is less effective for patients with more advanced disease. Data gathered at Duke University have shown that there is a significant cost gradient for angioplasty as the extent of disease increases (related to repeated procedures whose incidence may be reduced by stents), which is not apparent for coronary bypass (Figure 13) (737).

The use of drug-eluting stents in percutaneous revascularization will require a re-evaluation of cost-effectiveness considerations. The initial procedure is considerably more expensive (equaling the cost of CABG in many patients with multivessel disease), but the recurring cost of reintervention for restenosis will be dramatically reduced. Cost-effectiveness will depend on pricing of stents, utilization rates of the more expensive stents, and efficacy. All of these factors are evolving rapidly.

8.3. Cost Reduction in Coronary Bypass

Estimates presented in the previous portion of this section suggest that coronary bypass has been cost-effective in the last 2 decades. Initiatives to decrease the length of stay by using clinical pathways and standardized fast-track protocols have reduced hospital costs. Indeed, the estimates made by Weinstein and Stason are distinctly dated: improvements in outcomes and shortened lengths of hospitalization are likely to have considerably improved the cost-effectiveness of CABG (and angioplasty) since 1982.

Studies from the 1980s suggested that by concentrating CABG procedures into high-volume institutions, the overall cost of providing coronary surgical revascularization would be reduced owing to efficiencies of scale (738-740). Shahian et al (741) studied this question and found no relationship between either hospital size or annual CABG case volume and cost of performing bypass surgery.

A major innovation has been the introduction of off-bypass CABG, which has reduced the postprocedure length of stay to between 2 and 3 days. In some centers, this has led to a total 3-month cost for single-vessel coronary bypass that is not significantly different from the total 3-month cost for angioplasty of single-vessel disease (742). Considering the favorable long-term patency of an IMA graft to the LAD, the cost reductions possible with off-bypass CABG may improve the relative cost-effectiveness of coronary bypass compared with either medical therapy or percutaneous techniques, particularly for symptomatic, proximal LAD disease.

9. INDICATIONS

9.1. Introduction

The CABG operation is indicated both for the relief of symptoms and for the prolongation of life. The 1991 Guidelines focused on survival relative to medical therapy as the pivotal recommendation for operation. In addition to extension of the length of life, this operation is an important therapeutic tool for the relief of disabling symptoms.

The 1991 Guidelines state that "the evidence is complete that the coronary artery bypass operation relieves angina in most patients." The results of the randomized trials of CABG versus PTCA have confirmed and extended this conclusion (743,744). Not only did CABG effectively relieve angina in the symptomatic patients enrolled in the randomized trials, but also freedom from angina and from antianginal medications was superior in the CABG cohorts compared with PTCA cohorts. Bypass surgery also relieved angina better than coronary stents in a randomized trial comparing the 2 forms of therapy (137).

The benefit realized from the use of CABG to relieve disabling symptoms must be balanced against the risk of the operation and tempered by the potential activity level of the individual patient. This risk may be very low in selected groups of patients. In a series of 1386 patients with single- and double-vessel disease aged less than 66 years, without CHF, and an EF greater than 0.35 from the early 1980s at Emory University, a hospital mortality of 0.07% (1 patient) was reported. Not only did these young, healthy patients have a very low risk, but their potential for renewal of an active lifestyle was exceptionally high. CABG in patients such as these for relief of disabling angina after failure of medical therapy is an attractive option, even if no survival benefit can be predicted. If, on the other hand, one were to consider a 78-year-old patient with limiting arthritis and Class II angina, then the potential benefit of CABG will be considerably less and the risk comparably greater. In this case, the attractiveness of PTCA or continued medical therapy as the appropriate therapy is enhanced.

Some caution must be expressed in the use of CABG for relief of symptoms. CABG treats the manifestations of CAD, not the disease process. As coronary disease progresses, therefore, angina often returns. The hazard function for return of angina is low for the first 5 years after operation and then begins to rise, seemingly related to late closure of bypass conduits. So long as the patient and the healthcare practitioner understand that angina may return after 5 to 10 years, the application of CABG for the relief of angina rather than for survival benefit is appropriate, particularly in low-risk patients. If preoperative symptoms are disabling, there is a high probability for a return to a fully functional lifestyle and, as discussed in Section 8, the procedure is cost-effective as well.

The second important recommendation for CABG after relief of symptoms, is prolongation of life. The randomized trials of CABG versus medical therapy have defined patient subsets whose survival is enhanced. These patients tend to be those with advanced coronary disease: notably left main disease and triple-vessel disease (or double-vessel disease including a proximal LAD stenosis) combined with LV dysfunction. The survival benefit of CABG was examined in detail in the 1991 Guidelines and will be applied to specific patient subgroups in the following sections.

The explosive growth of PCI in the last decade mandates a careful examination of CABG survival versus PCI survival. Large randomized trials generally show that 7 to 8 year survival is superior for patients with diabetes undergoing CABG compared with patients with diabetes undergoing PTCA (131,130). Among patients without diabetes, there appears to be little difference in survival.

Only short-term results of stent revascularization are available at this time; however, similar trends favoring surgery in patients with diabetes are emerging. Definitive conclusions regarding stent procedures await maturation of ongoing clinical trials.

9.2. Clinical Subsets

9.2.1. Asymptomatic or Mild Angina

Class I

1. **CABG should be performed in patients with asymptomatic or mild angina who have significant left main coronary artery stenosis.** ***(Level of Evidence: A)***
2. **CABG should be performed in patients with asymptomatic or mild angina who have left main equivalent: significant (greater than or equal to 70%) stenosis of the proximal LAD and proximal left circumflex artery.** ***(Level of Evidence: A)***
3. **CABG is useful in patients with asymptomatic ischemia or mild angina who have 3-vessel disease. (Survival benefit is greater in patients with abnormal LV function; e.g., EF less than 0.50 and/or large areas of demonstrable myocardial ischemia.)** ***(Level of Evidence: C)***

Class IIa

CABG can be beneficial for patients with asymptomatic or mild angina who have proximal LAD stenosis with 1- or 2-vessel disease. (This recommendation becomes a Class I if extensive ischemia is documented by noninvasive study and/or LVEF is less than 0.50.) ***(Level of Evidence: A)***

Class IIb

CABG may be considered for patients with asymptomatic or mild angina who have 1- or 2-vessel disease not involving the proximal LAD (If a large area of viable myocardium and high-risk criteria are met on noninvasive testing, this recommendation becomes Class I). ***(Level of Evidence: B)***

For patients with no symptoms or mild angina, the appropriateness of coronary bypass surgical therapy is based on

Downloaded from circ.ahajournals.org by on August 4, 2008

survival advantage therapy compared with nonsurgical therapy. The relative appropriateness of percutaneous versus surgical therapy is discussed in Section 3.3. To identify anatomic subsets in which coronary bypass is beneficial, definition of "important" coronary stenosis is necessary. For this and all subsequent sections, coronary stenosis will be defined as a 50% or greater reduction of lumen diameter. This is the degree of narrowing defined as important in the majority of randomized trials that have examined the relationship of coronary anatomy and survival after CABG. It is important to note that the level of angina in this category is not considered an indication for surgery. Moderate or severe angina would represent symptoms that many patients find unacceptable despite adequate medical therapy. Contrariwise, in this category, patients are either completely asymptomatic or have acceptable symptoms such that bypass surgery for symptom relief is not the issue.

The indication for bypass surgery in this category relates to the extent of coronary disease, the demonstration of objective signs or symptoms of this disease, and consideration for the risk of nonmedical therapy, which may include either bypass surgery or angioplasty. As stated in Section 3.2, the data on which these classifications are assigned are based on 3 randomized controlled trials, several smaller randomized trials, a subsequent meta-analysis of these data, and several observational studies. The limitations of these data are discussed in Section 3.2 and listed in Table 7.

9.2.2. Stable Angina

Class I

1. **CABG is recommended for patients with stable angina who have significant left main coronary artery stenosis.** ***(Level of Evidence: A)***
2. **CABG is recommended for patients with stable angina who have left main equivalent: Significant (greater than or equal to 70%) stenosis of the proximal LAD and proximal left circumflex artery.** ***(Level of Evidence: A)***
3. **CABG is recommended for patients with stable angina who have 3-vessel disease. (Survival benefit is greater when LVEF is less than 0.50.)** ***(Level of Evidence: A)***
4. **CABG is recommended in patients with stable angina who have 2-vessel disease with significant proximal LAD stenosis and either EF less than 0.50 or demonstrable ischemia on noninvasive testing.** ***(Level of Evidence: A)***
5. **CABG is beneficial for patients with stable angina who have 1- or 2-vessel CAD without significant proximal LAD stenosis but with a large area of viable myocardium and high-risk criteria on noninvasive testing.** ***(Level of Evidence: B)***
6. **CABG is beneficial for patients with stable angina who have developed disabling angina despite maximal noninvasive therapy, when surgery can be performed with acceptable risk. If angina is not typical, objective evidence of ischemia should be obtained.** ***(Level of Evidence: B)***

Class IIa

1. **CABG is reasonable in patients with stable angina who have proximal LAD stenosis with 1-vessel disease. (This recommendation becomes Class I if extensive ischemia is documented by noninvasive study and/or LVEF is less than 0.50).** ***(Level of Evidence: A)***
2. **CABG may be useful for patients with stable angina who have 1- or 2-vessel CAD without significant proximal LAD stenosis but who have a moderate area of viable myocardium and demonstrable ischemia on noninvasive testing.** ***(Level of Evidence: B)***

Class III

1. **CABG is not recommended for patients with stable angina who have 1- or 2-vessel disease not involving significant proximal LAD stenosis, patients who have mild symptoms that are unlikely due to myocardial ischemia, or patients who have not received an adequate trial of medical therapy and**
   a. **have only a small area of viable myocardium or** ***(Level of Evidence: B)***
   b. **have no demonstrable ischemia on noninvasive testing.** ***(Level of Evidence: B)***
2. **CABG is not recommended for patients with stable angina who have borderline coronary stenoses (50% to 60% diameter in locations other than the left main coronary artery) and no demonstrable ischemia on noninvasive testing.** ***(Level of Evidence: B)***
3. **CABG is not recommended for patients with stable angina who have insignificant coronary stenosis (less than 50% diameter reduction).** ***(Level of Evidence: B)***

For patients with stable angina, the recommenation for CABG is based both on the likelihood of improving survival and on the likelihood of relief of lifestyle-limiting symptoms. Based on the 3 large, prospective, randomized trials comparing medical with surgical therapy and multiple observational studies, the patient factors most influencing a decision to recommend CABG include the presence of severe proximal multivessel coronary disease, LV dysfunction, a strongly positive stress test, and comorbid conditions such as PVD and diabetes. Additional factors that are of critical importance relate to the perceived immediate risk of bypass surgery and the long-term prognosis, particularly whether the patient's potential improvement in longevity or quality of life due to a successful bypass operation justifies the short-term risk.

9.2.3. Unstable Angina/Non–ST-Segment Elevation MI (NSTEMI)

Class I

1. **CABG should be performed for patients with unstable angina/NSTEMI with significant left main coronary artery stenosis.** ***(Level of Evidence: A)***
2. **CABG should be performed for patients with unstable angina/NSTEMI who have left main equivalent: significant (greater than or equal to 70%) stenosis of the proximal LAD and proximal left circumflex**

Downloaded from circ.ahajournals.org by on August 7, 2008

artery. *(Level of Evidence: A)*

3. **CABG is recommended for unstable angina/NSTEMI in patients in whom revascularization is not optimal or possible, and who have ongoing ischemia not responsive to maximal nonsurgical therapy.** *(Level of Evidence: B)*

Class IIa

CABG is probably indicated for patients with unstable angina/NSTEMI who have proximal LAD stenosis with 1- or 2-vessel disease. *(Level of Evidence: A)*

Class IIb

CABG may be considered in patients with unstable angina/NSTEMI who have 1- or 2-vessel disease not involving the proximal LAD when percutaneous revascularization is not optimal or possible. (If there is a large area of viable myocardium and high-risk criteria are met on noninvasive testing, this recommendation becomes Class I.) *(Level of Evidence: B)*

Indications for coronary bypass surgery in this category relate not only to survival but also to the relief of symptoms. Thus, in general, all of the survival indications listed for the asymptomatic patient or the individual with stable angina apply. However, timing of surgery becomes a critical consideration. Some reports have suggested a high mortality after CABG in patients with acute unstable angina or NSTEMI and have shown that one of the independent predictors of mortality after coronary bypass surgery is the stability of the patient going to operation. Other investigators have not found this association (Section 5.11). In the patient in whom stabilization with aggressive medical therapy may be achieved, it is advisable to stabilize and reduce ongoing ischemia before proceeding to bypass surgery. In this regard, a small randomized trial demonstrated that insertion of an IABP 2 hours or more before CPB can reduce bypass time, intubation time, and length of stay, and improve postoperative cardiac output in high-risk patients (745).

9.2.4. ST-Segment Elevation MI (STEMI)

Class I

Emergency or urgent CABG in patients with STEMI should be undertaken in the following circumstances:

a. **Failed angioplasty with persistent pain or hemodynamic instability in patients with coronary anatomy suitable for surgery.** *(Level of Evidence: B)*
b. **Persistent or recurrent ischemia refractory to medical therapy in patients who have coronary anatomy suitable for surgery, who have a significant area of myocardium at risk, and who are not candidates for PCI.** *(Level of Evidence: B)*
c. **At the time of surgical repair of postinfarction ventricular septal rupture or mitral valve insufficiency.** *(Level of Evidence: B)*
d. **Cardiogenic shock in patients less than 75 years old with ST-segment elevation or left bundle-branch block or posterior MI who develop shock within 36 hours of MI and are suitable for revascularization that can be performed within 18 hours of shock, unless further support is futile because of patient's wishes or contraindications/unsuitability for further invasive care** *(Level of Evidence: A)*
e. **Life-threatening ventricular arrhythmias in the presence of greater than or equal to 50% left main stenosis and/or triple-vessel disease** *(Level of Evidence: B)*

Class IIa

1. **CABG may be performed as primary reperfusion in patients who have suitable anatomy and who are not candidates for or who have had failed fibrinolysis/PCI and who are in the early hours (6 to 12 hours) of evolving STEMI.** *(Level of Evidence: B)*
2. **In patients who have had an STEMI or NSTEMI, CABG mortality is elevated for the first 3 to 7 days after infarction, and the benefit of revascularization must be balanced against this increased risk. Beyond 7 days after infarction, the criteria for revascularization described in previous sections are applicable.** *(Level of Evidence: B)*

Class III

1. **Emergency CABG should not be performed in patients with persistent angina and a small area of myocardium at risk who are hemodynamically stable.** *(Level of Evidence: C)*
2. **Emergency CABG should not be performed in patients with successful epicardial reperfusion but unsuccessful microvascular reperfusion.** *(Level of Evidence: C)*

Although early coronary bypass surgery as a primary reperfusion strategy in patients suffering from a STEMI has been reported, the widespread use of intravenous fibrinolytic therapy for this purpose and more primary PCI has largely superceded early application of bypass surgery. Studies have shown that eventual infarct size and the subsequent risk of mortality and/or LV dysfunction are related to the time from the onset of symptoms until coronary reperfusion. Although, on average, coronary bypass surgery requires a longer time to establish coronary reperfusion than either of the nonsurgical techniques, modification of the conditions of reperfusion that is possible with surgical therapy may offer some benefit with regard to eventual infarct size relative to percutaneous or fibrinolytic therapy. Despite this potential benefit of reperfusion modification, coronary bypass is rarely performed for this indication except in special circumstances. The decision to perform surgery requires angiographic demonstration of adequate target vessels in the region of infarction and usually other regions as well. In most circumstances, early coronary bypass for acute infarction is appropriate only in patients with residual ongoing

Downloaded from circ.ahajournals.org by on August 4, 2008

ischemia despite nonsurgical therapy, be it fibrinolysis, PCI, or both. As with PCI, the risks of bypass operation in patients in the midst of a STEMI are substantially higher than are the risks in elective candidates.

To determine the benefits and liabilities of treatment of an acute MI with CABG requires accurately defining the topic. The definition of acute MI is the resultant ischemic muscle injury after reduction or interruption of the coronary artery blood supply. The obvious weakness in this definition is the variability of the tissue damage. This has been addressed by sub-classifying MIs into Q-wave and non–Q-wave types. A Q-wave infarction has been defined as ST-segment changes that progress to new Q waves in addition to a creatine phosphokinase (CPK)-MB isoenzyme elevation of greater than 10 IU/L. Non–Q-wave infarction is defined as ST-segment and T-wave abnormalities (generally NSTEMI) that do not progress to pathological Q waves but show abnormal elevations of CPK-MB isoenzyme of greater than 10 IU/L (585). The decision or appropriateness to recommend surgical revascularization in the face of an acute MI depends on the clinical symptoms and the presence of persistent ischemia despite maximum medical therapy. This is also the algorithm that is used to decide to proceed with catheter-based therapy. It appears that when there is a situation that is not amenable to medical or catheter-based therapy and persistent ischemia is present, CABG is indicated. This is presuming that there is no overwhelming contraindication against operation.

There are specific conditions that will warrant CABG in the face of an acute MI: the presence of left main stenosis, severe 3-vessel disease, associated valve disease (whether secondary to the MI or unrelated) (35a), and anatomy unsuitable for other forms of therapy. The literature is somewhat vague regarding the categories for surgical intervention. Some of the reports address STEMI versus NSTEMI while others address the proximity of MI to operation (i.e., less than 6 hours, 6 hours to 2 days, 2 to 14 days, 2 to 6 weeks, and greater than 6 weeks) or unstable angina versus evolving MI, mechanical complications, acute occlusions, and control patients. It is best to review these separately and try to identify a common recommendation and approach.

Braxton et al (585) studied the comparative effect of operating on patients with STEMI and NSTEMI versus a control group. Excluding the patients who require emergency operation for mechanical complications of an acute MI, the patients undergoing CABG within 48 hours of the STEMI had a significantly increased operative mortality which approached 50%. The data imply that for such patients, there is much to be gained by waiting more than 48 hours in most circumstances. The implication is also made study also suggested that symptomatic patients with a NSTEMI may undergo surgical revascularization at any time with no significant increase in mortality over elective patients (585). This is substantiated in an article by Goodman et al (583), wherein MI after fibrinolytic therapy was evaluated in relation to events with STEMI versus NSTEMI. The NSTEMI was more likely to be nonanterior, distally located, and have better global and regional LV function. In the setting of fibrinolysis after MI, patients with a NSTEMI were more likely to have early, complete, and sustained infarct-related artery patency and better LV function. This identification of anatomic and functional differences between STEMI and NSTEMI should also translate into operative risk for these 2 patient cohorts and verifies the worse operative risk with surgery in the early STEMI period.

Creswell et al (581) retrospectively reviewed 2296 patients who underwent CABG after an acute MI. A generalization that was made was that the operative mortality decreased as the time between the acute MI and operation increased. Patients who underwent operation less than 6 hours after MI had an operative mortality of 8.4% and those who underwent operation greater than 6 hours, 4.3% (P equals 0.02) (Table 19). Additional findings were that despite the urgency of operation, operative mortality was greater for those patients with a preoperative MI than those without an MI. It is important to note that when the independent risk factors of urgency of operation, increased patient age, renal insufficiency, number of previous MIs, and hypertension were adjusted for, the time interval between MI and CABG was not a significant predictor of death.

A third way to examine the impact of an MI on operative mortality was reported by von Segesser et al (579). In this series, 641 of 3397 patients had stable or unstable angina, respectively, and underwent CABG. These 641 patients were divided into 5 groups. Group A patients had unstable angina that involved the inclusion of 2 of 6 criteria including impending infarction, electrocardiographic ST-segment modifications, minimal increases in CPK values, prolonged angina at rest, angina resistant to intravenous medication, and postinfarction angina. Group B patients were sustaining an evolving MI defined as either a new electrocardiographic Q wave; electrocardiographic ST-segment modifications;

Table 19. Coronary Artery Bypass Graft Surgery Mortality After Acute Myocardial Infarction: Effect of Timing of Operation

Outcome	Less than 6 Hours	6-48 Hours	2-14 Days	2-6 Weeks	Greater than 6 Weeks	No MI
Op mort	9.1%	8.3%	5.2%	6.5%	2.9%	2.1%
Periop MI	9.1%	9.8%	2.8%	2.7%	4.0%	3.9%
Trans CVA	0.0%	3.0%	1.3%	0.4%	0.8%	0.8%
Perm CVA	9.1%	3.8%	2.9%	1.5%	2.3%	1.2%
AF	27.2%	40.9%	33.0%	39.1%	31.8%	30.7%

MI indicates myocardial infarction; Op mort, operative mortality; Periop, perioperative; Trans, transient; CVA, cerebrovascular accident; Perm, permanent; and AF, atrial fibrillation.

and CPK-MB values greater than 8% of total CPK, CPK greater than 3 times normal; CPK-MB greater than 10% of total CPK; or new LV dyskinesis on echocardiography or scintigraphy. Group C patients had mechanical complications of acute MI. Group D patients had an acute coronary occlusion (emergency post-PTCA or angiography), and Group E patients had stable class IV angina (control).

In this series, acute CABG in patients with unstable angina, evolving MI, and acute coronary occlusion demonstrated results comparable to those of CABG in the elective cohort. Late survival in these 3 cohorts was similar to that of the group with stable angina. The worst late survival was in those with mechanical complications, although it was acceptable. The conclusions of this investigation support acute revascularizations in unstable angina and selected patients after acute MI.

A review of other articles dealing with operation after acute MI (34,450,580,746) suggests that unless patients are in cardiogenic shock or have mechanical complications of acute MI, early CABG can be performed with little or no increase in risk of perioperative mortality.

Mechanical complications of acute MI include ventricular septal defect, MR secondary to papillary muscle infarction and/or rupture, and LV free-wall rupture (747-754). There is general agreement that cardiogenic shock associated with a mechanical complication of an MI warrants emergency operation to correct the defect as a life-saving procedure. Although there is less consensus as to the timing of operation for patients with ventricular septal defect or MR after acute MI with hemodynamic stability, most cardiac surgical centers proceed promptly to surgery.

There does not appear to be clear documentation of the best timing for stable patients with a mechanical complication. There has been the argument to delay operation to allow the friable tissue to "mature" and hold sutures; this invokes some Darwinian selection process and prompted Norell et al (747) to approach all of these types of problems acutely. Their results did not demonstrate a statistical difference between acute and subacute operation. It must be stated, however, that the numbers in many of these series were small or included patient enrollment extending over several decades while techniques, understanding of physiology, and philosophy have advanced.

9.2.5. Poor LV Function

Class I

1. **CABG should be performed in patients with poor LV function who have significant left main coronary artery stenosis.** ***(Level of Evidence: B)***
2. **CABG should be performed in patients with poor LV function who have left main equivalent: significant (greater than or equal to 70%) stenosis of the proximal LAD and proximal left circumflex artery.** ***(Level of Evidence: B)***
3. **CABG should be performed in patients with poor LV function who have proximal LAD stenosis with 2- or 3-vessel disease.** ***(Level of Evidence: B)***

Class IIa

CABG may be performed in patients with poor LV function with significant viable noncontracting, revascularizable myocardium and without any of the above anatomic patterns. ***(Level of Evidence: B)***

Class III

CABG should not be performed in patients with poor LV function without evidence of intermittent ischemia and without evidence of significant revascularizable viable myocardium. ***(Level of Evidence: B)***

As discussed in Section 5.9, increasing evidence suggests that chronic LV dysfunction due to viable but hibernating myocardium in patients with severe multivessel disease is relatively common. Furthermore, observational studies now support the notion that coronary bypass surgery can result in stabilization and often improvement in LV function in selected patients. Operation on a patient with poor LV function is particularly appropriate if the patient has signs or symptoms of intermittent ischemia and minimal or no CHF. On the other hand, if the patient has prominent signs and symptoms of CHF with minimal angina, the decision to operate should be based on objective evidence of hibernating myocardium (755). There should be demonstration of substantial regions of myocardial viability that would benefit from revascularization (756). Such areas must be perfused by coronary arteries of sufficient size and location to be reasonable targets for bypass surgery (757).

The concept of operating on patients with poor LV function for survival advantage comes from the randomized trials that suggested that patients with left main, 3-vessel, and 2-vessel disease and vessel disease involving the proximal LAD with concomitant LV dysfunction on average had a greater survival advantage compared with those on medical therapy. Although the randomized studies did not include large numbers of patients with EFs less than 0.30, subsequent observational data suggest that these patients, although having a higher immediate risk for bypass surgery, may achieve a greater long-term gain in terms of survival advantage, assuming that the concepts discussed above are applied (755-757).

9.2.6. Life-Threatening Ventricular Arrhythmias

Class I

1. **CABG should be performed in patients with life-threatening ventricular arrhythmias caused by left main coronary artery stenosis.** ***(Level of Evidence: B)***
2. **CABG should be performed in patients with life-threatening ventricular arrhythmias caused by 3-vessel coronary disease.** ***(Level of Evidence: B)***

Class IIa

1. **CABG is reasonable in bypassable 1- or 2-vessel disease causing life-threatening ventricular arrhythmias. (This becomes a Class I recommendation if the arrhythmia is resuscitated sudden cardiac death or**

Downloaded from circ.ahajournals.org by on August 4, 2008

sustained ventricular tachycardia.) ***(Level of Evidence: B)***

2. **CABG is reasonable in life-threatening ventricular arrhythmias caused by proximal LAD disease with 1- or 2-vessel disease. (This becomes a Class I recommendation if the arrhythmia is resuscitated sudden cardiac death or sustained ventricular tachycardia).** ***(Level of Evidence: B)***

Class III

CABG is not recommended in ventricular tachycardia with scar and no evidence of ischemia. ***(Level of Evidence: B)***

The benefits of CABG in patients with ventricular arrhythmias have been studied in survivors of out-of-hospital cardiac arrest and in patients with inducible ventricular tachycardia or fibrillation under electrophysiological study. In general, bypass surgery has been more effective in reducing episodes of ventricular fibrillation than ventricular tachycardia, because the mechanism of the latter arrhythmia usually involves reentry with scarred endocardium rather than ischemia.

In survivors of cardiac arrest who have severe and operable coronary disease, CABG surgery can suppress arrhythmia induction, reduce subsequent cardiac arrest, and result in a good long-term outcome (758-760). It is particularly effective when an ischemic cause of the arrhythmia can be documented, for instance, with exercise (761). However, because coronary revascularization may not alleviate all of the factors that predispose to ventricular arrhythmias, concomitant insertion of an implantable cardioverter-defibrillator may be necessary (762). Similarly, continued inducibility or clinical recurrence of ventricular tachycardia after CABG usually requires defibrillator implantation.

9.2.7. CABG After Failed PTCA

Class I

1. **CABG should be performed after failed PTCA in the presence of ongoing ischemia or threatened occlusion with significant myocardium at risk.** ***(Level of Evidence: B)***
2. **CABG should be performed after failed PTCA for hemodynamic compromise.** ***(Level of Evidence: B)***

Class IIa

1. **It is reasonable to perform CABG after failed PTCA for a foreign body in crucial anatomic position.** ***(Level of Evidence: C)***
2. **CABG can be beneficial after failed PTCA for hemodynamic compromise in patients with impairment of the coagulation system and without previous sternotomy.** ***(Level of Evidence: C)***

Class IIb

CABG can be considered after failed PTCA for hemodynamic compromise in patients with impairment of the coagulation system and with previous sternotomy. ***(Level of Evidence: C)***

Class III

1. **CABG is not recommended after failed PTCA in the absence of ischemia.** ***(Level of Evidence: C)***
2. **CABG is not recommended after failed PTCA with inability to revascularize due to target anatomy or no-reflow state.** ***(Level of Evidence: C)***

The decision to proceed with emergency bypass surgery after a failed PTCA procedure is a complex one. The interventional cardiologist and consulting cardiac surgeon must together decide when the procedure cannot be salvaged by percutaneous techniques, often in the acute setting of ischemia or infarction. Important considerations include the mechanisms of the failed procedure, the potential to correct this situation surgically, the extent of myocardium that is jeopardized, and the overall clinical status of the patient. Threatened compared with acute vessel closure poses a particularly challenging situation, since the physicians must balance further attempts at percutaneous salvage versus moving forward with surgery. Factors that influence the outcome of surgery include patient characteristics such as LV dysfunction, older age, and previous MI (763,764), as well as anatomic factors such as complex lesion characteristics, extent of multivessel disease, and the absence of collaterals (763-766). Finally, outcome also depends on the total ischemic time and may be adversely affected by a delay in transport to the operating room (763,764,767,768). Bypass surgery is clearly the procedure of choice in the setting of hemodynamic compromise or for retrieval of a foreign body, such as a fractured guidewire or undeployed stent in a crucial anatomic position.

Emergency bypass for failed PTCA is understandably associated with a higher rate of death and subsequent MI compared with elective bypass surgery (763,769). It is encouraging to observe the diminishing need for emergency bypass surgery in this situation, owing in large measure to the increasing use and availability of intracoronary stents (643,645). Among patients who require emergency bypass after a failed angioplasty in the current era, the rate of complications remains substantial (770-772). This probably reflects the increased severity of CAD and other comorbidities in patients currently treated with PTCA. Therefore, a coordinated approach and cooperative interaction between the cardiologist, cardiac surgeon, and anesthesia team are necessary to expedite resuscitation, transfer, and revascularization of patients with failed PTCA (773-775).

9.2.8. Patients With Previous CABG

Class I

1. **Coronary bypass should be performed in patients with prior CABG for disabling angina despite optimal nonsurgical therapy. (If angina is not typical,**

Downloaded from circ.ahajournals.org by on August 4, 2008

then objective evidence of ischemia should be obtained.) ***(Level of Evidence: B)***

2. **Coronary bypass should be performed in patients with prior CABG without patent bypass grafts but with Class I indications for surgery for native-vessel CAD (significant left main coronary stenosis, left main equivalent, 3-vessel disease).** ***(Level of Evidence: B)***

Class IIa

1. **Coronary bypass is reasonable in patients with prior CABG and bypassable distal vessel(s) with a large area of threatened myocardium by noninvasive studies.** ***(Level of Evidence: B)***
2. **Coronary bypass is reasonable in patients who have prior CABG if atherosclerotic vein grafts with stenoses greater than 50% supplying the LAD coronary artery or large areas of myocardium are present.** ***(Level of Evidence: B)***

Reoperation after previous CABG can be successfully performed, but the risk of hospital mortality is increased about 3-fold compared with the primary operation. Moreover, reoperation is associated with a diminished expectation for relief of symptoms and a diminished expectation for prolongation of life compared with the primary operation (see Sections 4.1.2 and 5.7). For this reason, reoperation is generally reserved for relief of disabling symptoms or for compelling evidence of potentially life-threatening areas of myocardium at risk objectively quantified by noninvasive studies. Because many of these patients have had previous myocardial damage, consideration of the consequences of infarction of an area of myocardium demonstrated to be at risk must be weighed against the cumulative effect of the current threatening situation combined with prior damage.

The existence of significant late stenoses (greater than or equal to 5 years after operation) representing atherosclerosis in vein grafts that are greater than 50% stenosed and that supply either the LAD coronary artery or large areas of myocardium represent a potential anatomic indication for operation.

For a patient with previous bypass surgery, percutaneous techniques can be effective in treating native-vessel stenoses and appear to be safe in treating early stenoses in vein grafts. However, the use of percutaneous techniques to treat late atherosclerotic stenoses in vein grafts has been much less successful.

An increasingly common situation is the presence of a functioning IMA graft to the LAD artery, with recurrent ischemia in other regions of the heart. The potential loss of this conduit consequent to a reoperation represents a major negative factor in the long-term therapy of that patient and is cause for additional caution in recommendation of a reoperation.

Corrections

In the article by Antman et al, "ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction—Executive Summary: A Report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines (Writing Committee to Revise the 1999 Guidelines for the Management of Patients With Acute Myocardial Infarction)," which appeared in the August 3, 2004, issue of the journal (*Circulation.* 2004:110:588–636), the following errors occur:

- Table 3 (p 619): In the footnote entry "How to Use the Table," the example text states that Temporary transvenous pacing (TV) is Class IIb, whereas the table shows TV to be Class IIa. This should be Class IIa in both instances.
- Table 4 (p 626): The footnote entry listing the source of the data is incorrect. The correct citation should be "Smith et al. *Circulation.* 2001;104:1577–1579."
- Page 630: The recommendation for Cardiac Rehabilitation programs should be a Class I recommendation, not a Class IIa recommendation.

The corrected version of this article is available online at http://circ.ahajournals.org/cgi/content/full/110/5/588. (The previous version, if needed, can be accessed by selecting the "Previous Version of This Article" link.)

DOI: 10.1161/01.CIR.0000163465.65091.7A

In the article by Antman et al, "ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction: A Report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines (Committee to Revise the 1999 Guidelines for the Management of Patients With Acute Myocardial Infarction)," which appeared in the August 31, 2004, issue of the journal (*Circulation.* 2004;110:e82–e292), the following errors occur:

- Table 12 (p e127): The entry "Traumatic or prolonged (greater than 10 minutes) CPR or major surgery (within less than 3 weeks)" should read "Traumatic or prolonged (greater than 10 minutes) CPR or major surgery (less than 3 weeks)."
- Table 13 (p e129): In the Model column for CCP and for InTIME-2, the SBP values on admission of 170 mm Hg or greater=1 entries should be deleted.
- Table 23 (p e166): Row 2 is incorrect. It should read "2. IV or D5W to keep the vein open. Start a second IV if IV medication is being given. This may be a heparin lock."
- Table 23 (p e166): Row 3 is incorrect. It should read "3. Vital signs: every 30 min until stable, then every 4 h as needed. Notify physician if HR is less than 60 bpm or greater than 100 bpm, systolic BP is less than 100 mm Hg or greater than 150 mm Hg, respiratory rate is less than 8 breaths per minute or greater than 22 breaths per minute."
- Table 23 (p e166): Row 5 is incorrect. It should read "5. Diet: NPO except for sips of water until stable. Then start 2 gram sodium/day, low saturated fat (less than 7% total calories/day), low cholesterol (less than 200 mg/d) diet, such as Therapeutic Lifestyle Changes (TLC) diet."
- Table 23 (p e166): Row 6 is incorrect. It should read "6. Activity: Bedrest and bedside commode and light activity when stable."
- Table 29 (p e198): Column 1 is missing a heading. It should read "Normal."
- Table 29 (p e199): The "How to Use the Table" footnote line 4 states that Temporary transvenous pacing (TV) is Class IIb, whereas the table according to the instructions shows that TV should be Class IIa. The footnote should read Class IIa.
- Page e237: The entry for Class I number 9 is incorrect. It should read "Class I. Cardiac

Preamble

The granting of clinical staff privileges to physicians is a primary mechanism used by institutions to uphold the quality of care. The Joint Commission on Accreditation of Health Care Organizations requires that the granting of continuing medical staff privileges be based on the criteria specified in the medical staff bylaws. Physicians themselves are thus charged with identifying the criteria that constitute professional competence and with evaluating their peers accordingly. Yet, the process of evaluating physicians' knowledge and competence is often constrained by the evaluator's own knowledge and ability to elicit the appropriate information, problems compounded by the growing number of highly specialized procedures for which privileges are requested.

The American College of Cardiology Foundation/American Heart Association/American College of Physicians (ACCF/AHA/ACP) Task Force on Clinical Compe-

Downloaded from circ.ahajournals.org by on August 4, 2008

tence and Training was formed in 1998 to develop recommendations for attaining and maintaining the cognitive and technical skills necessary for the competent performance of a specific cardiovascular service, procedure, or technology. These documents are evidence based and, where evidence is not available, expert opinion is utilized to formulate recommendations. Indications and contraindications for specific services or procedures are not included in the scope of these documents. Recommendations are intended to assist those who must judge the competence of cardiovascular health care providers entering practice for the first time and/or those who are in practice and undergo periodic review of their practice expertise or who apply for privileges at a new institution. The assessment of competence is complex and multidimensional, therefore, isolated recommendations contained herein may not necessarily be sufficient or appropriate for judging overall competence. The current document addresses competence in cardiac interventional procedures and is authored by representatives of the ACCF, the AHA, and the Society for Cardiovascular Angiography and Interventions (SCAI). This document applies to specialists trained in internal medicine and/or adult cardiology and is not meant to be a clinical competence statement on procedures for congenital heart disease in the child or young adult.

The ACCF/AHA/ACP Task Force makes every effort to avoid any actual or potential conflicts of interest that might arise as a result of an outside relationship or personal interest of a member of the ACCF/AHA/ACP Writing Committee. Specifically, all members of the Writing Committee were asked to provide disclosure statements of all such relationships that might be perceived as real or potential conflicts of interest relevant to the document topic. These statements were reviewed by the Writing Committee and updated as changes occurred. The relationships with industry for authors and peer reviewers are published in the appendices of the document.

Mark A. Creager, MD, FACC, FAHA
Chair, ACCF/AHA/ACP Task Force on
Clinical Competence and Training

Introduction

Coronary intervention has evolved from an investigational procedure to a widely practiced, mature mainstream clinical therapy (1). Conventional balloon angioplasty, while still a core procedure in interventional cardiology, has been augmented by adjunctive stenting, which greatly improves procedure efficacy and modestly reduces the risk of restenosis (2). Bare-metal stents have been replaced by drug-eluting stents in the majority of cases, which further reduce the risk of restenosis (3). Because stents or other interventional devices are commonly used, the coronary angioplasty procedure is more aptly termed "percutaneous coronary intervention" (PCI).

The AHA estimated that more than 1,000,000 PCIs were performed in the United States in 2003 (4). Physicians performing these procedures represent approximately 25% of board-certified cardiologists in the United States (5).

As a result of the maturation of PCI as a discipline and the ongoing clarification of its role in the management of coronary heart disease, the public can and should appropriately expect consistent access to high-quality PCI capability. However, there is potential for substantial variation in the quality of PCI services. PCI is often a complex, demanding procedure. To perform PCI optimally, an operator must possess a substantial cognitive knowledge base as well as considerable technical skill. In addition, the technical difficulty of a particular procedure can vary greatly from one patient to another. Furthermore, serious complications of coronary interventional procedures may occur unpredictably in procedures that initially appear to be straightforward. Recognition and management of complications are critical components of PCI procedures that require skill, knowledge, experience, and judgment. Since there can be variation among operators in cognitive knowledge and skill and among procedures in technical difficulty, there is a potential for substantial variation in procedure safety and efficacy.

Credentialing physicians to perform procedures is the responsibility of the governance of the local health care facility. The Joint Commission on the Accreditation of Health Care Organizations requires that medical staff privileges be granted to applicants only after assessment based on professional criteria. Physicians are charged with the responsibility to establish the criteria that constitute professional competence and to evaluate their peers on the basis of such criteria. The U.S. health care system relies, in part, on this process of granting and renewing clinical privileges to maintain quality.

The issue of determining quality standards and credentialing criteria has presented a major challenge to the medical profession. Developing standards has been difficult because, until recently, there were few data available on which to base them and because PCI techniques, indications, and capability have evolved rapidly. During the past several years, documents have been published that have offered guidelines and standards for the training and maintenance of competence (6–15). Because of the paucity of clinical data, the earlier standards were developed principally through observation, experience, and intuition. These standards relied heavily on operator activity level as a surrogate for skill and quality.

The most recent document published by the ACC was based on the information available in 1998 (16). The recommendations of this and other similar documents require updating as technology and training evolve (17).

Percutaneous noncoronary cardiac interventions, such as aortic and mitral valvuloplasty, atrial septal defect (ASD) and patent foramen ovale (PFO) closure, and alcohol septal ablation therapy, were not addressed in the previous document (16). These procedures, although constituting a

Downloaded from circ.ahajournals.org by on August 4, 2008

0280
09/15/08

small minority of interventional activity, are performed by interventional cardiologists and are included in the Accreditation Council on Graduate Medical Education (ACGME) curriculum and the American Board of Internal Medicine (ABIM) certifying exam. There have been no statements addressing clinical competence in noncoronary interventions.

The ACC, the ACP, the SCAI, the Society for Vascular Medicine and Biology (SVMB), and the Society for Vascular Surgery (SVS) have jointly developed a document on acquisition and maintenance of competence in vascular medicine and catheter-based vascular interventions (18); however, PCI and other percutaneous cardiac procedures are not addressed by the current document. This document is divided into 2 sections: PCI and percutaneous noncoronary cardiac interventions.

Purpose

This document was developed to review the currently available scientific data with the following purposes:

1. To characterize the expected success and complication rates for coronary interventional procedures when performed by highly skilled operators.
2. To identify comorbidities and other risk factors that may be used for risk adjustment when assessing procedure-specific expected success and complication rates.
3. To assess the relationship between operator activity level and success rates in PCI procedures as assessed by risk-adjusted outcome statistics.
4. To assess the relationship between institutional activity level and success rates in PCI procedures as assessed by risk-adjusted outcome statistics.
5. To develop recommendations for standards to assess operator proficiency and institutional program quality. These include standards for data collection to permit monitoring of appropriateness and effectiveness of PCI procedures both at the level of the operator and the institution.
6. To expand the scope of this competency document, previously limited to coronary procedures, to also include noncoronary cardiac interventions.

Writing Group Composition

The Writing Group was selected to represent a broad range of experience and expertise to bear on this issue. The members of the Writing Group were identified on the basis of 1 or more of the following attributes: PCI operators with a broad range of experience (in practice and in academic settings); individuals who have performed clinical research studying the outcome of PCI procedures; individuals who direct catheterization laboratories with a broad cross section of interventional operators; and individuals with broad clinical experience who have had considerable previous involvement with PCI.

Literature Review

A literature search was conducted with 5 goals:

1. To identify published coronary and other cardiac interventional outcomes data that could be used as benchmarks for quality assessment. In addition, the process sought to identify those risk adjustment variables that affect the likelihood of success and complications. This review focused on outcomes of coronary interventions, including the latest interventional devices as of the date of this revision.
2. To identify data that examines the relationships between operator and institutional experience, and activity levels, and their impact on procedural success and complication rates.
3. To assess the issues and problems associated with judging operator and institutional proficiency based on outcome statistics—in particular, the challenge of accurately assessing the performance of low-volume operators and institutions.
4. To expand the recommendations beyond coronary interventions to other cardiac interventional procedures.
5. To identify methods for monitoring appropriateness of performance of PCI.

Percutaneous Coronary Intervention

Evolution of Competence and Training Standards

Initially, because experience was limited, the coronary angioplasty technique was disseminated informally among physicians who were highly experienced at diagnostic cardiac catheterization. During this period, physicians acquired angioplasty skills through "on-the-job" experience, and no standards existed for either training requirements or for demonstration of competence.

As the coronary angioplasty knowledge base grew and techniques evolved, standards were developed for training (19). Formal angioplasty training programs were first organized in the early 1980s. The most recent recommendations were published by the ACC in 1999 (20). The ABIM developed an Examination in Interventional Cardiology that was first administered in 1999. As of 2005, 5,020 physicians had successfully passed the examination and become board certified in interventional cardiology. Currently, eligibility to sit for the ABIM interventional cardiology examination requires completion of a fourth-year fellowship in interventional cardiology in an ACGME-accredited program. During academic year 2004 to 2005, there were 122 accredited interventional cardiology programs in the United States that had 240 filled training positions.

Professional organizations have addressed the issue of standards and criteria for proficiency in PCI procedures since 1986, with an increasing focus on the issue of

Downloaded from circ.ahajournals.org by on August 4, 2008

0281
09/15/08

maintenance of proficiency and skills (6–15). These documents have universally endorsed an annual caseload goal for maintenance of proficiency. The most commonly endorsed activity level has been 75 procedures per year per operator. This standard was initially based on general consensus of experts. In recent years, considerable research has examined the volume–outcome relationship and, in general, has affirmed it (21,22).

Since the previous guidelines were published, there has been debate over the relationship between volume and quality. While a relationship between volume and outcomes exists, volume alone does not determine quality. Also, the ABIM interventional cardiology board exam has been established to certify a level of knowledge and experience in the field. This competency document addresses these factors as they relate to determinations of overall operator and institutional quality.

Evolution of Coronary Interventional Capabilities

The cognitive and technical knowledge base required for proficiency in PCI has expanded. The fundamental concepts of coronary angioplasty technique, namely the coaxial guide catheter and the dilation catheter with a minimally compliant cylindrical balloon, were formulated by Andreas Gruntzig (23). Because of the initial comparatively primitive equipment design and capability, coronary angioplasty was only applicable to readily accessible discrete proximal coronary stenoses. Subsequent refinement in instrumentation has greatly enhanced procedural success and extended the indications for the performance of PCI. Complex anatomic situations now considered technically suitable for PCI procedures include multivessel disease (24–30), distal and bifurcation stenoses, total occlusions (31), saphenous vein graft stenoses (32), and complex stenoses. Challenging clinical situations now considered appropriate for coronary intervention include patients with unstable angina (33,34) and myocardial infarction (MI) (35,36) and those who are not considered candidates for coronary bypass surgery.

Nonballoon devices, including coronary stents, and directional, rotational, and laser atherectomy devices, have been introduced. These devices augment conventional balloon angioplasty and extend its capability; however, they all require specific training and mentoring by a previously experienced operator. To become competent in the use of any of these newer interventional devices, an operator must acquire the additional knowledge and technical skills specific to each device.

A number of adjunctive antithrombotic and antiplatelet medications have been introduced for the purpose of reducing acute thrombus-related treatment site complications. Understanding the appropriate indications for and complications associated with the use of these medications, which are powerful anticoagulants, requires knowledge of hemostatic mechanisms.

Procedural Success and Complications of Coronary Interventional Procedures

Recent clinical studies have demonstrated that despite a continuing increase in clinical and angiographic complexity, procedural and clinical success rates have remained high and complication rates have remained low (37–45) (Table 1). Angiographic success occurs in over 95% of patients. Among patients without ST-segment elevation myocardial infarction (STEMI), PCI is associated with an average mortality rate of less than 1%, a Q-wave MI rate of less than 1%, and an emergency coronary artery bypass surgery (CABG) rate of less than 1%. Table 1 contains data from 5 large contemporary registries of PCI procedures and the first 2 National Heart, Lung, and Blood Institute (NHLBI) registries for historical comparison. These data constitute a point of departure for developing benchmarking standards.

Adverse events related to PCI procedures are categorized either by the mechanism of the complication or by the adverse event caused by the procedure. A given adverse event, such as death, may be caused by a variety of complications.

Complications can be divided into 3 mechanistic categories:

1. **Coronary vascular injury.** Coronary arterial injury can occur when devices are introduced into coronary vessels or result from embolization of thrombotic or atherosclerotic material from devices or vessel walls. Examples include coronary dissection, thrombosis, perforation, and embolization.
2. **Other vascular events.** Other vascular events are caused either by injury to a peripheral vessel by catheter insertion, manipulation, or removal, or by embolization of thrombotic or atherosclerotic material. Examples include pseudoaneurysm, retroperitoneal hemorrhage, arteriovenous fistula, and stroke.
3. **Systemic nonvascular events.** Systemic nonvascular adverse events are caused by the procedure but are not due to vascular injury. They include all the systemic hazards of cardiovascular radiographic angiography procedures. Examples include contrast agent-induced nephropathy and acute pulmonary vascular congestion.

For the purpose of assessing clinical competence, complications may be divided into 8 basic outcome categories:

1. **Death**: related to the procedure, regardless of mechanism
2. **Stroke**
3. **MI**: related to the procedure, regardless of mechanism
4. **Ischemia requiring emergency CABG**: either as a result of procedure failure or a procedure complication
5. **Vascular access site complications**
6. **Contrast agent nephropathy**
7. **Excessive bleeding, requiring treatment**
8. **Other (such as coronary perforation and tamponade)**

The first 4 of these categories are generally considered major adverse cardiac and cerebral events (MACCE). Be-

cause adverse events are definite end points, they are easily recognized and captured for statistical summary purposes. The ACC-National Cardiovascular Data Registry (NCDR)® has developed a comprehensive data dictionary with rigorous definitions of recognized adverse events (46). It may be impossible to determine conclusively whether death or a complication was caused by a procedure. Nonetheless, for the purposes of monitoring performance, rate of complications or deaths substantially above that expected, after adjustment for patient risk factors, is a cause for concern.

Patient, Lesion, and Institutional Variables Influencing Success and Complication Rates

A number of factors have improved the overall success and complication rates of PCI procedures. These include increased operator experience, modifications in conventional instrumentation (balloon catheters, guide catheters, guide wires), newer interventional devices (stents and embolization protection devices), and advances in adjunctive pharmacologic therapy. Concurrently, these improvements have led to the extension of interventional treatment to higher-risk patients with more complex coronary anatomy and comorbid disease. These factors have influenced overall acute and long-term outcome associated with PCI procedures.

Measures/Definitions of Success

Anatomic success. The definition of anatomic success focuses exclusively on the enlargement of the lumen at the target site and blood flow through the epicardial coronary artery. Although there has been disagreement, the current definition of success of PCI with stenting is the achievement of a minimal diameter stenosis of less than 20% as visually assessed by angiography and maintenance of Thrombolysis In Myocardial Infarction (TIMI) flow grade 3 (15). Anatomic success of PCI without stenting is defined as stenosis diameter reduction greater than 20% with residual stenosis less than 50%. Notably, there is frequently a disparity between the visual estimate of lumen diameter and quantitative measurements (47,48).

Procedural success. Procedural success has been defined as the achievement of anatomic success of all treated lesions without the major complications of death, MI, or emergency CABG (14,40). Although emergency CABG during hospitalization and death are easily identified end points, the definition of periprocedural MI has been more problematic. Some definitions require the development of Q waves in addition to a threshold value for creatine kinase (CK) elevation. However, more recent reports have included non-STEMIs with CK elevations greater than 3 or 5 times the upper limit of normal as clinically significant, since they have been shown to correlate with long-term mortality (49). Although major adverse cardiac events (MACE) have been

Downloaded from circ.ahajournals.org by on August 4, 2008

0283
09/15/08

used to judge success, some recent studies also include MACCE.

Short-term clinical success. Short-term clinical success requires, in addition to procedural success, the relief of signs and symptoms of myocardial ischemia.

Longer-term clinical success. Longer-term clinical success requires that the initial clinical success remains durable and that the patient has persistent relief of signs and symptoms of myocardial ischemia for 6 to 9 months after the procedure. Restenosis remains the principal cause of a lack of clinical success over the first year following a successful procedure. This directly leads to target lesion revascularization (TLR), target vessel revascularization, and target vessel failure. Thereafter, clinical events are usually caused by progression of disease at other sites. Clinically important restenosis may be judged by the frequency with which subsequent TLR procedures are performed after the index procedure. Incomplete revascularization, new lesion formation, and stent thrombosis may also limit long-term clinical success, especially in subsequent years (50).

Patient and Lesion Characteristics Related to Procedural Success and Complication Rates

Angioplasty procedural success and complication rates are influenced by a variety of patient and target lesion characteristics. These characteristics must be taken into consideration through risk adjustment when assessing adverse event rates. In addition, they must also be weighed in determining procedure appropriateness.

Patient clinical characteristics. The clinical factors associated with an increased risk of an adverse outcome after intervention include advanced age, female gender, acute coronary syndrome (especially STEMI), chronic renal insufficiency, heart failure, and multivessel coronary disease (7,12,14,15). Patients with impaired renal function, particularly patients with diabetes, are at increased risk for contrast-induced nephropathy (51).

Target lesion anatomic factors. Particular lesion morphologic characteristics are predictive of immediate outcome with coronary intervention (7,12,14,52). Lesion length, presence of thrombus, and degenerated saphenous vein grafts are independently associated with abrupt vessel closure and major ischemic complications. Chronic total occlusions (greater than or equal to 3 months) are associated with a lower procedural success rate. On the basis of these observations, a previous ACC/AHA Clinical Task Force on Clinical Privileges in Cardiology (13) proposed a classification scheme based on lesion morphology to estimate the likelihood of procedural success and complications. This scheme was subsequently modified by others (52) and has served as a useful guide for assessing the risk of an adverse outcome associated with a particular lesion. More recent experience indicates that improved devices and techniques have higher success rates in more complex lesions (53–56). As a result, lesion morphology may be less predictive of complications currently than it has been in the past (57).

Strategies for Risk Stratification and Operator Evaluation

Several large retrospective studies of patients undergoing PCI have identified clinical and angiographic characteristics that correlate with procedural success, in-hospital morbidity, and mortality (21,22,44) (Table 2). These observations have been used to develop multivariate logistic regression models that can stratify patients before the procedure. Model reliability is best assessed by relative predictive accuracy (C-statistic: moderate is greater than 0.80, excellent is greater than 0.90) and scaling accuracy (the Hosmer-Lemeshow statistic). Several models predict periprocedural mortality with C-statistic greater than 0.80 (Table 2). Prediction of other events is typically less accurate (58–60). Model utility also must consider the frequency and clinical importance of the event measured. Very infrequently occurring events, even if severe, may not allow adequate evaluation of operators with low volume. Results of several years of experience should be considered in order to have sufficient numbers of events to be adequately assessed from a statistical standpoint. Operators and catheterization laboratories should be encouraged to submit information to large databases that allow for evaluation of risk-adjusted outcomes.

Impact of the Facility on Procedural Success

Physical facility requirements. The physical facility in which interventional procedures are performed has an important impact on procedural success. The facility must provide radiologic equipment, monitoring, and patient support equipment to enable operators to perform at the best of their ability. The video and "cine" image quality of radiologic imaging equipment must be optimal to facilitate accurate catheter and device placement and enable proper assessment of procedure results. Physiologic monitoring equipment must provide continuous, accurate information about the patient's condition. Requisite support equipment must be available and in good operating order to respond to emergency situations.

Overall institutional system requirements. The interventional laboratory must have an extensive support system of specifically trained laboratory personnel. Cardiothoracic surgical, respiratory, and anesthesia services should be available to respond to emergency situations in order to minimize detrimental outcomes. The institution should have systems for credentialing, governance, data gathering, and quality assessment. Prospective, unbiased collection of key data elements on consecutive patients and consistent feedback of results to providers brings important quality control to the entire interventional program. The ACC/AHA/SCAI 2005 Guideline Update for PCI (15) recommends that each interventional program performing elective PCI

should have in-house surgical support. Institutions that do not have in-house surgical support and are performing primary PCI only for STEMI, should have an established, well-organized system for emergency transfer to surgery at another institution.

Components of Operator Competence

Cognitive Knowledge Base

The knowledge needed to perform PCI, including that expected to be acquired in ACGME-approved interventional training programs, has been addressed by expert panels (7,8,20,67,68). The core knowledge is now tested by the ABIM Interventional Cardiology certifying examination which has been administered since 1999. Through 2003, physicians trained by a nontraditional pathway were eligible to take the examination based on either practice-based procedure activity and experience or by completion of an interventional training program. Since 2003, only individuals who have completed an ABIM-qualified training program are eligible to take the certifying examination. Individuals who train in interventional cardiology should become ABIM certified in interventional cardiology.

Training programs and the qualifying examination (20,69) require that interventional cardiologists be knowledgeable in anatomy, physiology, and pathophysiology of the cardiovascular system. In particular, one should understand the biology of coronary artery disease, be knowledgeable about the pathophysiology of myocardial ischemia and MI, and understand the dynamics of cardiac dysfunction. Interventionalists should possess a fundamental knowledge of stents and be familiar with the polymers and drugs that are incorporated into stents, coagulation cascade, thrombosis, and the pharmacology, therapeutic application, and risks of antiplatelet, antithrombin, and fibrinolytic drugs that are used in association with PCI. Competent operators must have knowledge of the indications for PCI and adjunctive and alternative use of medical therapy and surgery for patients with coronary artery disease based on an in-depth

Downloaded from circ.ahajournals.org by on August 4, 2008

0285
09/15/08

understanding of published clinical trials. Coronary interventionalists must understand the role of primary angioplasty compared with fibrinolytic therapy for STEMI and the alternative therapeutic approaches for treating STEMI that depend upon the time of presentation, anticipated door-to-balloon time, and the presence or absence of ongoing symptoms and/or electrocardiographic abnormalities.

Cognitive knowledge must be bolstered by clinical skills and experience that support the rational selection of optimal treatment strategies for each patient. Such decisions are based on symptoms, anatomy, and associated risk factors. Thus, equally important to knowing the indications for PCI is an understanding of its limitations and contraindications, particularly as these relate to comorbid systemic diseases and special anatomical subsets. Physicians performing these procedures should be conversant with the applicable guidelines (e.g., PCI, CABG, STEMI, unstable angina/NSTEMI [15,70–72]).

Coronary interventionalists must also have a thorough knowledge of specialized equipment, techniques, and devices used to perform PCI competently, including:

1. The theoretical and practical aspects of X-ray imaging, radiation physics and safety, and other equipment to generate digital images; quality control of images; image archiving; consequences of exposure of patients and personnel to ionizing radiation; and methods of reducing patient and staff radiation exposure (73).
2. Specialized catheterization recording and safety equipment (physiological data recorders, pressure transducers, blood gas analyzers, defibrillators) (74).
3. Catheters, guide wires, balloon catheters, stents, atherectomy devices, ultrasound catheters, intra-aortic balloon pumps, puncture site sealing devices, contrast agents, distal protection devices, and thrombus extraction devices.

Operators must be knowledgeable about the prevention, prompt recognition, and treatment of procedural complications. It is extremely important to have the knowledge and skills to diagnose and manage vessel perforation, no reflow, coronary dissection, expanding hematoma, pseudoaneurysm, arterial venous fistulas, and retroperitoneal hemorrhage. Interventionalists must also be cognizant of systemic complications, including cerebrovascular events and contrast-related nephropathy.

Technical Skills

Many of the skills required to perform coronary interventional procedures are closely related to those needed to perform diagnostic cardiac catheterization and coronary angiography. These include manual dexterity and the ability to obtain percutaneous arterial and venous access and maintain sterile surgical technique.

Most of the other required technical skills are unique to coronary interventional procedures and can only be acquired during training and by performing actual procedures under the direction of an experienced interventionalist. These include the manipulation and operation of guide catheters, coronary angioplasty guide wires, coronary angioplasty balloon catheters, specialized atherectomy devices, stents, and intracoronary ultrasound catheters. Such training appropriately occurs in standardized training programs that are ACGME-approved and lead to eligibility for board certification.

Nonballoon Devices

A special area of competence involves use of lesion assessment tools. Intracoronary devices commonly used by interventional cardiologists for assessment of intraluminal coronary anatomy and/or physiology include intravascular ultrasound (IVUS) or intracoronary ultrasound (ICUS), Doppler flow wires, and pressure wires. Competency in the use of angioscopy, optical coherence tomography, spectroscopy, intravascular thermography, and intravascular magnetic resonance imaging is beyond the scope of this document. Expertise in device manipulation and image interpretation is required to use these intravascular assessment devices safely and effectively. The risks of these devices is the same as those with PCI and include vessel spasm; myocardial ischemia; coronary artery dissection; plaque disruption; thrombosis; air, plaque, or thrombotic embolization; acute occlusion; coronary artery perforation; and contrast nephropathy, stroke, and access site complications. Therefore, only an interventional cardiologist skilled in transluminal coronary techniques such as balloon angioplasty and stenting who is able to diagnose and treat complications of interventional procedures should employ these devices. Recommendations regarding the use of IVUS, Doppler flow wires, and pressure wires are published in Appendix C of the ACC/AHA Guidelines for Coronary Angiography (75).

It is also important to ensure quality image acquisition, measurement, and reporting for each of the intravascular assessment devices. For ICUS, the reader is referred to the ACC Clinical Expert Consensus Document on Standards for Acquisition, Measurement and Reporting of Intravascular Ultrasound Studies (76). No such documents are available for Doppler analysis of coronary flow reserve and pressure wire analysis of fractional flow reserve, but many of the general principles in the IVUS document may be of some benefit in guiding appropriate use of these other modalities.

Table 3. Published Data Relating Hospital Coronary Angioplasty Volume to Complication Rates

Study	Data Source	No. of Patients/ Hospitals Studied	Conclusions	Comments
Hartz et al. (78)	1989–1991 Wisconsin Medicare	2,091/16	No relation between volume and outcome	Very low number of cases and hospitals examined
Ritchie et al. (86)	1989 California State (Adm)	24,883/110	Increased CABG (not death) less than 20 cases per yr; finding is valid for both acute MI and nonacute MI patients	
Jollis et al. (85)	1987–1990 MEDPAR (Adm)	217,836/1,194	Death and CABG increased with low volume (risk increases with Medicare patient volume* (less than 100–200 total per yr for death, 200–300 per yr for CABG)	
Kimmel et al. (84)	1992–1993 SCAI	19,594/48	Fewer major complications for labs with greater than 400 cases per yr	Able to risk adjust more completely than most other analyses
GUSTO (IIb) Angioplasty Substudy Group (36)	GUSTO IIb trial	565/59	No difference, 200–625 vs. greater than 625 cases per yr for acute MI patients	All operators greater than or equal to 50 cases per yr
Kato et al. (79)	1991 HCFA (RAND Corp.)	113,576/862	Except for Medicare volume* less than 50, higher volume hospitals had higher mortality rates	
Stone et al. (80)	PAMI II trial	1,100/34	No difference, less than 500, 501–1,000, greater than 1,000 cases per yr for acute MI patients	
Jollis et al. (77)	1992 Medicare (Adm)	97,498/984	Incremental decrease in death and bypass surgery as hospital Medicare volume* less than 100, 100–200, greater than 200 per yr	
Tiefenbrunn et al. (83)	Second National Registry of MI (U.S.)	4,939/?	Increased acute MI mortality for hospital less than 25 acute MI cases per yr	
Hannan et al. (82)	1991–1994 NY State	62,670/31	Death alone and same-stay CABG increased with annual caseloads less than 600	Risk-adjusted
Zahn et al. (81)	1992–1995 German Hospital Consortium	4,625/?	For patients with acute MI; increased mortality in hospitals with less than or equal to 40 acute MI PTCA per yr	No risk-adjusted
Moscucci et al. (22)	1998–1999 NY State and MI	11,374/8	In-hospital death increased for hospital volume less than 400	Risk-adjusted
Hannan et al. (21)	1998–2000 NY State	107,713/34	Death, same-day CABG, same-stay CABG increased for hospital volume less than 400	Risk-adjusted

*Medicare patients usually constitute 35% to 50% of total interventional caseload.

many physicians and epidemiologists expert in the field were used to compile the relevant available scientific evidence relating institutional and operator activity level to outcomes (Table 3). In general, greater weight was given to recent, fully peer-reviewed publications of high quality. No single work was considered definitive. It was recognized that many analyses were limited to some extent by lack of capacity to fully adjust expected outcomes for differences in patient characteristics, changes and advances in the field of interventional cardiology, and inability to generalize the results to a broader population.

Relationship of Institutional Volume to Procedural Outcome

The preponderance of data suggest that, on average, hospitals in which fewer coronary interventions are performed have a greater incidence of procedure-related complications, notably death and need for bypass surgery for failed intervention, than hospitals performing more procedures. Multiple data sources support the existence of a curvilinear, perhaps logarithmic, statistical relation between caseload and outcome (Fig. 1). However, for CABG, the continued importance of the relationship between volume and outcomes has been recently confirmed using contemporary clinical data (87). For PCI, the majority of the studies available either predate the widespread introduction in interventional practice of coronary stenting and adjunctive use of glycoprotein receptor blockers, or were obtained through analysis of Medicare claims data or other administrative data. Recognized limitations of Medicare data include the need to extrapolate the total number of proce-

dures from the number of Medicare procedures, the incomplete reporting in Medicare claims of comorbidities that might be important predictors of adverse outcomes (16,17), and the possibility of miscoding complications as comorbidities (18).

The direct relationship between institutional volume and outcomes has been recently confirmed by 2 more contemporary analyses of large clinical registries. The first study compared data collected between 1998 and 1999 in a multicenter PCI registry in Michigan with data from the New York State data registry (22). An institutional annual volume less than 400 cases per year was found to be independently associated with an increased risk of in-hospital death compared with hospitals with annual volumes of at least 400 (adjusted odds ratio [OR] 1.77, 95% confidence interval [CI] 1.16 to 2.70). The second study (21), based on the New York State data registry, evaluated 107,713 procedures performed in 34 hospitals in New York State during 1998 to 2000. The same hospital volume threshold of less than 400 procedures per year was found to be associated with an increased risk of in-hospital mortality (adjusted OR 1.98, 95% CI 1.17 to 3.35), "same day" CABG surgery (adjusted OR 2.07, 95% CI 1.36 to 3.15) or "same stay" CABG surgery (adjusted OR 1.51, 95% CI 1.03 to 2.21). Figure 1 from the New York study presents the continuous relationship between hospital volume and risk-adjusted in-hospital mortality.

It is important to underscore that advancements in technology have resulted in a progressive improvement in outcomes of PCI, and that this improvement has at least in part offset the adverse institution volume–outcome relationship. In a recent study evaluating temporal trends in the volume–outcome relationship in the state of California, it was found that over time, the disparity in outcomes between low- and high-volume hospitals had narrowed, and that outcomes had improved significantly for all hospitals (88). The author of this study concluded that given these improvements, lower minimum volume standards might be justifiable in less populated areas, where the alternative is no access to angioplasty at all. Importantly, procedural volume is only one of many factors contributing to the variability of measured outcomes (58,82,89). Furthermore, there is no clear "cut-off" above or below which hospitals, or groups of hospitals in aggregate, perform well or poorly. There are institutions with low volumes that appear to achieve very acceptable results. For an individual institution, however, such an impression must be tempered by the statistical imprecision of the estimate of risk.

Volume and Outcomes Relationship for Primary PCI in Acute MI

The relationship between operator and institutional volume and outcome of primary PCI for acute MI has been examined nearly exclusively at hospitals with onsite cardiac surgery. In an analysis including 62,299 patients with acute MI and enrolled in the National Registry of Myocardial Infarction, Magid et al. (90) analyzed data from 446 acute-care hospitals providing primary angioplasty services. Hospitals were classified as low volume (less than 16 procedures per year), intermediate volume (17 to 48 procedures per year), and high volume (more than 49 procedures per year). In high-volume hospitals, mortality for acute MI patients was significantly lower with primary angioplasty when compared with fibrinolysis, while in low-volume hospitals, there were no differences in mortality rates between primary angioplasty and fibrinolysis. Two other

Downloaded from circ.ahajournals.org by on August 4, 2008

0288
09/15/08

analyses from the same registry and 2 studies using the New York State data registry have shown a direct relationship between hospital volume of primary angioplasty and mortality. In the analysis by Canto et al. (91), hospital volume was divided in quartiles. In-hospital mortality was 28% lower in patients treated in the highest volume quartile (greater than 33 primary PCIs per year) when compared with patients treated in the lowest volume quartile (less than 12 primary PCIs per year). Similar results were obtained by Cannon et al. (92). In this analysis, a procedure volume greater than 3 PCIs per month was found to be associated with a lower in-hospital mortality rate when compared with a procedure volume of less than 1 PCI per month, or with a procedure volume between 1 and 3 PCIs per month.

Recently, Hannan et al. (21) reported data from the New York State Coronary Angioplasty Reporting System Registry collected in the years 1998 to 2000, a period when stenting was used in a large majority of the STEMI patients. A trend toward an increased odds ratio of in-hospital mortality was observed for low-volume operators when compared with high-volume operators both for a volume cut of 8 procedures per year (OR 1.40, 95% CI 0.89 to 2.20) and with a volume cut of 10 procedures per year (OR 1.27, 95% CI 0.87 to 1.87). Importantly, a significant increase in the odds of in-hospital mortality was observed with lower institutional volume of primary PCI, regardless of whether the institutional volume cut point was set at 36 procedures per year (OR 2.01, 95% CI 1.27 to 3.17), 40 procedures per year (OR 1.73, 95% CI 1.1 to 2.71), or 60 procedures per year (OR 1.45, 95% CI 1.01 to 2.09).

Volume and outcomes relationship for PCI in hospitals without onsite cardiac surgery. There is only 1 report indicating a relationship between institutional PCI volume and outcome in hospitals without onsite cardiac surgery. Wennberg et al. (93) reported that among Medicare recipients, there was no difference in mortality after primary/rescue PCI (emergency procedure on the same day for STEMI) performed at hospitals with or without cardiac surgery onsite. However, they did report a higher mortality for PCI patients, excluding primary/rescue PCI, at hospitals without cardiac surgery onsite (adjusted OR 1.38, 95% CI 1.14 to 1.67; $p = 0.001$). The relationship between institutional volume and PCI affecting this outcome was confined mainly to hospitals without cardiac surgery onsite performing 50 or fewer nonprimary/rescue PCIs in Medicare recipients per year. Among hospitals performing more than 100 PCIs in Medicare recipients, mortality was not higher in hospitals without surgery onsite (adjusted OR 0.76, 95% CI 0.52 to 1.11; $p = 0.16$). These hospitals likely perform more than 200 PCIs per year based on the assumption that 100 Medicare PCIs represent approximately 200 total PCIs per year.

Taken together, these data suggest that the *relationship* between institutional volume of PCI patients (excluding primary/rescue PCI) and mortality in hospitals without surgery onsite may be similar to the relationship in hospitals with surgery onsite. For facilities without onsite surgery, it is mandatory that there be an established, well-organized plan for transfer for surgery if needed.

Relationship of Individual Operator Volume to Procedural Outcome

Several large studies have assessed the potential relation between individual operator caseload and procedural complications (93). Recently, McGrath et al. (94) analyzed relatively contemporary data (calendar year 1997) from the Medicare database. Based on a slightly different assumption than Wennberg et al. (93) that Medicare patients represent 35% to 45% of total PCI procedure volume, they estimated that 30 PCIs per operator per year on Medicare patients could be extrapolated to a total procedure volume of 70 PCIs per operator per year (94). A significant relationship between operator volume and outcomes was also reported in their study, with better outcomes observed in patients treated by high-volume operators when compared with patients treated by low-volume operators. Similar results were obtained in the study by Hannan et al. (21) in the analysis of data collected from the 107,713 procedures performed in the 34 hospitals performing PCI in New York State during 1998 to 2000. Operator volume thresholds were set at 75 procedures per year based on ACC/AHA recommendations, and at slightly higher levels of 100 and 125 procedures per year. There were no differences in risk-adjusted mortality between patients undergoing PCI performed by lower volume operators and patients undergoing PCI performed by higher volume operators for any of the 3 volume thresholds that were examined. However, for all 3 volume thresholds, significant differences for "same day" CABG surgery and for "same stay" CABG surgery were observed. For example, patients undergoing PCI with operators performing less than 75 procedures per year had a 65% increased odds of undergoing same-day CABG surgery, and a 55% increased odds of undergoing "same-stay" CABG surgery.

Further confirmation of the adverse operator volume–outcome relationship with contemporary PCI comes from an analysis by Moscucci et al. (95) of another regional, audited, clinical PCI registry. In that analysis including 18,504 procedures performed in 14 Michigan hospitals in calendar year 2002, operator volume was subdivided in quintiles (1 to 33 PCIs per year, 34 to 89 PCIs per year, 90 to 139 PCIs per year, 140 to 206 PCIs per year, and 207 to 582 PCIs per year). The primary end point was a composite of MACE, including death, CABG, stroke, transient ischemic attack, MI, and repeat PCI at the same lesion site. Stent utilization was greater than 80%, and greater than 70% of patients received a glycoprotein ($GP_{IIb/IIIa}$) receptor inhibitor. After adjustment for comorbidities, patients treated by operators in the 2 lower volume quintiles (Quintiles 1 and 2) had a 63% increase in the odds of MACE

Relationship between operator volume and adverse outcome in contemporary percutaneous coronary intervention practice: an analysis of a quality-controlled multicenter percutaneous coronary intervention clinical database. J Am Coll Cardiol 2005; 46:625–32 (95). MACE = major adverse cardiac events.

(Fig. 2). No significant relationship was observed between operator volume and risk of in-hospital death. The adverse relationship between operator volume and outcomes appeared to be relatively independent of patient risk. A detailed analysis of individual operator risk-adjusted outcomes revealed the presence of several low-volume operators with better than expected outcomes, and of a few high-volume operators with worse than expected outcomes, thus suggesting that there are exceptions to the rule, and that low-volume operators should be tracked over a longer period of time to ascertain their true performance (Fig. 3).

Combination of Individual Operator Volume and Institutional Volume on Procedural Outcome

The combined impact of hospital volume and operator volume on adverse outcomes was assessed by Hannan et al. (21). Patients undergoing PCI performed by operators with volumes below 75 per year in hospitals with volumes below 400 per year were found to have significantly higher odds of dying in the hospital than patients undergoing PCI performed by operators with volumes of 75 or more in hospitals with volumes of 400 or more (OR 5.92, 95% CI 3.25 to

09/15/08

10.97). Also, patients undergoing PCI performed by operators with annual volumes of below 75 in hospitals with annual volumes below 400 experienced significantly higher same-day CABG rates than patients with high-volume operators (greater than 75 annually) in high-volume hospitals (greater than 400 annually), with an OR of 4.02. For same-stay CABG surgery the respective OR was 3.19. It should be noted that the magnitude of these ORs demonstrates that the increase in adverse outcomes compound when patients undergo PCIs performed by low-volume operators (less than 75 annually) in low-volume hospitals (less than 400 annually).

In summary, analysis of more contemporary data supports the hypothesis that technological advancements have not completely offset the influence of "practice" in determining proficiency of contemporary PCIs. However, procedure volume is only a poor substitute for quality and outcomes; therefore, it should not be used as a replacement for appropriately risk-adjusted outcomes. Nevertheless, it is easy to measure, and its potential implications are easily understood by patients undergoing PCI. As such, it seems appropriate to continue to include procedure volume among the several indirect quality indicators of contemporary PCI practice.

However, it is also important to underscore that there are significant limitations to the simplistic interpretation of procedure volume statistics as a measure of competence and quality. First, it is uncertain whether this relationship is a result of the "practice makes perfect" principle, or the fact that patients are more frequently referred to high-quality operators. Second, it remains unclear where the "cut-off" number should be set. Third, studies have shown significant variability in the volume–outcome relationship within the same registry, with some low-volume operators having better than expected outcomes, and a few high-volume operators having worse-than-expected outcomes. Furthermore, at present, few or no data exist linking operator volume to case selection, appropriateness of procedures, periprocedural MI, long-term clinical outcome, or cost-effectiveness, each of which measures a component of quality of care, or linking clinical outcomes to operator experience as measured by the number of years in practice, total procedure volume over a lifetime career, or board certification.

The development of national, regional, and state registries for outcome assessment is also promoting a shift of the paradigm surrounding quality of PCI from a mere collection of procedure volume to objective assessment of clinical outcomes. In addition, the past decade has been characterized by substantial advancement in methodology, scientific rigor, and acceptance of risk adjustment. Factors related to in-hospital mortality following PCI are now well defined, and progress is being made toward the development of statistical models for other outcomes. Clearly, the calculation of risk-adjusted outcomes using data from clinical registries is a more accurate way to assess outcomes than using volume as a surrogate, and as more registry data become available, procedure volume will likely no longer be used as a replacement or a surrogate for quality assessment.

Yet, limitations related to the effect of random variation and to the evaluation of rare events continue to exist. These limitations make it difficult to assess the true performance of very-low-volume operators. In such situations, close scrutiny of case selection and close monitoring of outcomes on a case-by-case basis might serve as a substitute/complement to risk adjustment.

In summary, while there are inherent limitations in using procedure volume as a surrogate of quality and outcomes, recent data suggest that there is still a relationship between experience and outcomes. In the analysis of the New York State data, the relationship appeared to be at a level of 75 procedures per year, with further improvement in outcomes observed at a volume threshold of greater than 100 procedures per year. In the analysis of the Michigan data, the relationship was at a level of 100 procedures per year. On the basis of these data, it is recommended that the operator volume threshold continue to be 75 procedures per year. Independent of procedure volume, all operators should participate in a regional or national program for outcome assessment and quality improvement. In addition, it is recognized that there are limitations in the application of the risk-adjustment methodology in the evaluation of rare events and of low-volume operators, and that there might be substantial variations in the volume–outcome relationship. For operators that do not meet a threshold of 75 cases per year measured in 2-year intervals, it is recommended that a case-by-case review, case selection, and prior experience including the total number of cases in a lifetime career be included in their evaluation. They could also partner with higher volume operators to perform cases together to gain further experience.

Ongoing Quality Improvement and Maintenance of Competence

Maintenance of competence in interventional procedures should be accomplished for both the individual physician operator and for the institutions in which cardiac interventional procedures are performed. The goals in setting criteria for maintaining competence include:

1. Ensuring quality of patient care and outcomes;
2. Enabling quality interventionalists and institutions to continue to perform PCI;
3. Providing standards that all institutions and operators should strive to achieve.

Institutional Maintenance of Quality

It is recommended that all institutions have a regular (at least monthly) catheterization laboratory conference. The opportunity for ongoing dialogue and collaboration among angiographers, interventional operators, and cardiothoracic surgical colleagues is highly desirable. New developments in

Downloaded from circ.ahajournals.org by on August 4, 2008

0291
09/15/08

the angioplasty literature should be reviewed, and procedural complications should be discussed.

Maintenance of competence also requires that patient outcomes be determined longitudinally for each procedure by the institution's quality assessment program. Participation in a state, regional, or national database is highly encouraged. This allows institutions to measure risk-adjusted outcomes and compare them to regional and national benchmarks for improving quality of care.

It is recommended that lower volume institutions (less than 400 interventions per year) consider holding conferences with a partnering, more highly experienced institution. It is also recommended that any institution that falls outside the risk-adjusted national benchmarks in mortality or emergency same-stay CABG during 2 of 3 contiguous 6-month periods have an external audit looking for opportunities to improve quality of care.

Individual Maintenance of Quality

To maintain a cognitive knowledge base, it is recommended that individual operators attend at least 30 h of interventional cardiology continuing medical education (CME) every 2 years. This could include catheterization conferences and PCI meetings in addition to expanding the use of simulation cases for procedure use and competence.

To ensure appropriate patient selection and quality of technical skills, it is recommended that all operators have 5 randomly selected cases and all major complications reviewed each year by the catheterization laboratory director or a Quality Assessment Committee at the institution. Any operator performing less than 75 cases per year should have 10 cases reviewed per year. These performance evaluations should include feedback to the operator. If it is determined that the quality of PCI care being provided does not meet national benchmarks, the catheterization laboratory director should have the discretion of making recommendations for improving quality and reassessing over the next 6 months. If disagreements concerning corrective action occur, external review is often helpful.

Quality Assurance

Definition of Quality in PCI

Satisfactory quality in PCI may be defined as selecting patients appropriately for the procedure and achieving risk-adjusted outcomes that are comparable to national benchmark standards in terms of procedure success and adverse event rates. To achieve optimal quality and outcomes in PCI it is necessary that both the physician operator and the supporting institution be appropriately skilled and experienced.

Institutional Quality Assurance Requirement

In the United States, responsibility for quality assurance is vested in the health care institution that is responsible to the public to ensure that patient care conducted under its jurisdiction is of acceptable quality. Quality assessment review should be conducted both at the level of the entire program and at the level of the individual practitioner.

Each institution that performs PCI must establish an ongoing mechanism for valid peer review of its quality and outcomes. The program should provide an opportunity for interventionalists as well as physicians who do not perform angioplasty, but are knowledgeable about it, to review its overall results on a regular basis. The review process should tabulate the results achieved both by individual physician operators and by the overall program and compare them to national benchmark standards with appropriate risk adjustment. Valid quality assessment requires that the institution maintain meticulous and confidential records that include the patient demographic and clinical characteristics necessary to assess appropriateness and to conduct risk adjustment.

Role of Risk Adjustment in Assessing Quality

A raw adverse event rate that is not appropriately risk adjusted has little meaning. Data compiled from large registries of procedures performed in recent years have generated multivariate risk adjustment models for adverse event rates for PCI in the current era. Six multivariate models of the risk of mortality following PCI have been published (62,64,96–99).

Although these models differ somewhat, they are consistent in identifying acute MI, shock, and age as important risk stratification variables for mortality. The ACC-NCDR® reported an univariate in-hospital mortality of 0.5% for patients undergoing elective PCI, mortality of 5.1% for patients undergoing primary PCI within 6 h of the onset of STEMI and mortality of 28% for patients undergoing PCI for cardiogenic shock (64). Thus, it is clear that, in order to assess PCI mortality rates, patients should be stratified by whether they are undergoing elective PCI, primary PCI for acute STEMI without shock, or primary PCI for STEMI with shock.

Challenges in Determining Quality

Given the complexity of case selection and procedure conduct, quality is difficult to measure in PCI and is not determined solely by adverse event rates even when properly risk adjusted. Accurate assessment of quality becomes more problematic for low-volume operators and institutions because absolute event rates are expected to be small. Thus, particularly in low-volume circumstances, quality may be better assessed by an intensive case-review process conducted by recognized experts who can properly judge all of the facets of the conduct of a case. Case review also has merit in high-volume situations as it can identify subtleties of case selection and procedure conduct that may not be reflected in pooled statistical data.

Table 4. Key Components of a Quality Assurance Program

Clinical proficiency
• General indications/contraindications
• Institutional and individual operator complication rates, mortality, and emergency coronary artery bypass grafting
• Institutional and operator procedure volumes
• Training and qualifications of support staff
Equipment maintenance and management
• Quality of laboratory facility (see ACC/SCAI Expert Consensus Document on Catheterization Laboratory Standards [100])
Quality improvement process
• Establishment of an active concurrent database to track clinical and procedural information and patient outcomes for individual operators and the institution. Participation in multicenter database is highly encouraged.
Radiation safety
• Educational program in the diagnostic use of X-ray
• Patient and operator exposure

Requirement for Institutional Resources and Support

A high-quality PCI program requires appropriately trained, experienced, and skilled physician operators. However, the operator does not work in a vacuum. An operator needs a well-maintained high-quality cardiac catheterization facility to practice effectively. In addition, the operator depends on a multidisciplinary institutional infrastructure for support and response to emergencies. Thus, to provide quality PCI services, the institution must ensure that its catheterization facility is properly equipped and managed, and that all of its necessary support services, including data collection, are of high quality and are readily available.

The Quality Assessment Process

Quality assessment is a complex process that includes more than a mere tabulation of success and complication rates. Components of quality in coronary interventional procedures include appropriateness of case selection; quality of procedure execution; proper response to intraprocedural problems; accurate assessment of procedure outcome both short- and long-term; and appropriateness of postprocedure management. It is important to consider each of these parameters when conducting a quality assessment review. A quality program performs appropriately selected procedures while achieving risk-adjusted outcomes, in terms of procedure success and complication rates, that are comparable to national benchmark standards. It is accepted that quality assurance monitoring is best conducted through the peer-review process despite the political challenges associated with colleagues evaluating each other. There has been considerable controversy surrounding efforts to define standards, criteria, and methodologies for conducting quality assessment. There are many challenges to conducting this process in a fair and valid manner.

The cornerstone of quality assurance monitoring is the assessment of procedure outcomes in terms of success and adverse event rates. Other components of quality assurance monitoring include establishing criteria for assessing procedure appropriateness and applying proper risk adjustment to interpret adverse event rates. As adverse events should be rare, a valid estimate of a properly risk-adjusted adverse event rate generally requires tabulating the results of a large number of procedures. This adds an additional challenge to the valid assessment of low-volume operators and institutions. The responsible supervising authority should monitor the issues outlined in Table 4.

In addition, mere tabulation of adverse event rates, even with appropriate risk adjustment, is inadequate to judge operator or program quality. Such tabulations do not address numerous other quality issues—in particular, appropriateness. Thus, the quality assessment process should also conduct detailed reviews of both cases that have adverse outcomes, to determine the cause(s) of the adverse event, and of uncomplicated cases, in order to judge case selection appropriateness and procedure execution quality. These reviews should be conducted by recognized experienced interventionalists, drawn either from within the institution or externally, if a requisite number of appropriately qualified unconflicted individuals are not available.

Conclusions and Recommendations for PCIs

In formulating conclusions and recommendations it is important to emphasize that the ultimate goal of setting standards is to facilitate the attainment of optimal patient outcomes. Optimal outcome is most likely when operators select clinically appropriate patients for interventional procedures and perform these procedures at a requisite level of proficiency. Institutional and programmatic quality is ultimately determined by its success in achieving that goal.

Success and Complication Rates

Coronary interventional procedures may be complex and technically demanding to perform. Complications of these procedures may be life-threatening and can occur unpredictably. Nonetheless, recent clinical studies have demonstrated that despite increased clinical and angiographic complexity, procedural and clinical success has remained high and complications have remained low. Angiographic success (at least 1 lesion successfully dilated by greater than 20%, with a residual stenosis of less than 50%), excluding

Downloaded from circ.ahajournals.org by on August 4, 2008

0293
09/15/08

STEMI patients, occurs in over 95% with an average mortality rate of less than 1%, a Q-wave MI rate of less than 1%, and an emergency CABG rate of less than 1%.

Risk Adjustment

Several large retrospective studies have identified both clinical and angiographic characteristics of PCI that correlate with procedural success, hospital morbidity, and mortality. These studies have been used to develop multivariate logistic regression models that can stratify patients into risk groups before the procedure which have moderate predictive value for mortality (C-statistic 0.85 to 0.90), and slightly less predictive value for morbidity (C-statistic 0.67 to 0.78).

Volume–Activity Relationships

Analysis of more contemporary data supports the hypothesis that technological advancements have not offset the influence of "practice" in determining proficiency of contemporary PCIs. There are statistical associations between activity levels and short-term complication rates (emergency CABG and mortality) (17,58,85,89,97,101) for both institutions and for individual operators. In particular, low-volume operators operating at low-volume hospitals had an increased mortality rate. However, procedural volume is only one of many factors contributing to the variability of measured outcomes. Furthermore, there is no clear "cut-off" above or below which hospitals or individual operators perform well or poorly. Procedural volume continues to be correlated with outcomes, but should not serve as a substitute for a well-controlled analysis of results and does not ensure quality. The development of national, regional and state registries for outcome assessment is promoting objective assessment of clinical outcomes.

The expected low complication rate for coronary interventional procedures presents a major statistical power problem when attempting to estimate the true complication rate of the low-volume operator with meaningful precision. In such situations, close scrutiny of case selection and close monitoring of outcomes on a case-by-case basis would serve as a complement to risk adjustment.

Highly complex procedures require much more skill and experience, and should be undertaken by operators possessing these attributes. Complex cases appropriate for interventions should be referred, not denied.

Recommendations for Institutional Maintenance of Quality

It is recommended that all institutions have a regular (at least monthly) catheterization laboratory conference. Patient outcomes should be determined longitudinally for each procedure by the institution's quality assessment program. Participation in a state, regional, or national registry is highly encouraged to allow institutions to measure risk-adjusted outcomes and compare them to national benchmarks for improving quality of care.

For both institutional and individual volume assessments, ongoing 2-year volumes should be measured, then averaged to arrive at annual statistics. It is recommended that lower volume institutions (less than 400 per year) consider holding conferences with a more experienced partnering institution, with all staff expected to attend on a regular basis.

It is also recommended that any institution that falls more than 2 standard deviations outside the risk-adjusted national benchmarks in mortality or emergency same-stay CABG during 2 of 3 contiguous 6-month periods have an external audit looking for opportunities to improve quality of care.

An institution offering coronary interventional procedures should have a physician-director who is responsible for the program's overall quality. The director should be certified in interventional cardiology by the ABIM, with a career experience of more than 500 procedures. The director should perform procedures at the facility that he or she directs.

Recommendations for Individual Maintenance of Quality

To maintain an appropriate cognitive knowledge base for PCIs, it is recommended that individual operators attend at least 30 h of PCI CME every 2 years. The overall performance of physicians whose complication rates exceed national benchmark standards for 2 of 3 contiguous 6-month periods should be reviewed by the program director, with careful attention to statistical power and risk-adjustment issues. It is recommended that the operator volume threshold continue to be 75 procedures per year. Monitoring of physicians with an annual procedural volume of less than 75 should be particularly detailed because of the difficulty of estimating their true complication rate. These performance evaluations should include feedback to the operator.

If it is determined that the quality of PCI care being provided does not meet national benchmarks, the catheterization laboratory director should have the discretion of making recommendations for improving quality and reassessing over the next 6 months. These recommendations could include establishing a defined mentoring relationship with an experienced operator. If the operator in question disputes this assessment, then external review may be helpful in determining the most appropriate methods of assuring quality performance.

Percutaneous Noncoronary Interventions

Introduction

Noncoronary interventions are a growing and important contribution to the field of interventional cardiology. The majority of procedures have had their origin in the pediatric population, and several have expanded to the adult patient. The purpose of this section is to discuss the training and experience necessary for the safe and successful performance

Downloaded from circ.ahajournals.org by on August 4, 2008

0294
09/15/08

of valvuloplasty, alcohol septal ablation, and percutaneous repair of ASD/PFO.

The knowledge, skills, and training necessary for competency in noncoronary interventional procedures are different from that required for coronary interventions. Therefore, special study of the anatomy, physiology, and pathology of these conditions is a prerequisite for safe and effective treatment. Furthermore, an in-depth understanding of the clinical indications for treatment and the unique complications of these treatments are essential.

Although the scope of this document is focused on competency, this section will expand the discussion somewhat to describe some anatomical and procedural details. Such details are well known for PCI, and their performance is widespread, whereas these noncoronary procedures, in the estimation of this Writing Committee, warrant some discussion of background information and procedural alternatives.

Disorders of the Atrial Septum

Criteria for Competency

The knowledge base required for performing PCI is different than that required for percutaneous closure of ASD and PFO. Extensive knowledge of structural cardiac anatomy, especially that of the atrial septum and the adjacent structures, is required, as is the understanding of the impact of abnormal anatomy and function, and the relative value of therapeutic options (85,101–105). Therefore, specific training and experience is necessary to safely and successfully treat this subgroup of patients. The Food and Drug Administration guidelines on the use of device closure of PFOs in these patients state that only patients who have failed anticoagulation or have a compelling medical reason to not be anticoagulated are appropriate for device closure. These guidelines should be fully discussed with patients during the informed consent process. In addition, complications such as cardiac perforation, device embolization, thrombus formation on the device, infective endocarditis, arrhythmias, and early as well as late erosion of the device through the atrial wall or aorta should be disclosed. Currently, 2 studies are underway comparing percutaneous closure of PFO to standard oral anticoagulation, which should clarify the indications for interventional treatment.

Since these procedures are relatively new to interventionalists trained in adult cardiology, no pre-existing guidelines are available on which to base current opinion. In the absence of such guidelines, we arrived at these recommendations from discussions with colleagues actively performing these percutaneous closures.

Cardiologists in Training Programs

Acquisition of the knowledge and skills necessary to perform percutaneous procedures to treat ASD and PFO should be incorporated into the formal training of interventional cardiologists. There are no data regarding the minimum number of cases required for maintenance of competency and proficiency. A survey of Pediatric Cardiology Interventional Catheterization training programs concluded that a minimum of 10 percutaneous ASD closures is necessary for a trainee to gain clinical competence with the procedure (102).

With this in mind, it is recommended that interventional cardiologists who intend to perform these procedures independently, should be involved in these procedures during training with at least 10 of these cases being secundum ASD closures. Furthermore, as part of the procedure, the fellow should be fully conversant in the use of transesophageal echocardiography and/or intracardiac echocardiography. He or she should understand how to obtain the appropriate views to image necessary structures in order to perform the procedure safely and to exclude other anatomical problems such as a primum or sinus venosus ASD, anomalous pulmonary venous drainage, fenestrated or multiple ASD, or lipomatous hypertrophy of the septum. Obviously, not all fellows in training will be able to gain this experience and, therefore, concentrating the experience in training should be limited to a few trainees.

Cardiologists in Practice

Interventional cardiologists in practice who were not specifically trained in ASD/PFO closure but would like to perform these procedures should be fully credentialed in interventional techniques in their institution. The first several cases should be done with a proctor. To ensure safety and success, it seems prudent that the first 10 cases be proctored by someone fully credentialed in these techniques such as a pediatric cardiologist or adult cardiologist trained in congenital heart disease. Proctors should also be present for the first 3 to 5 cases if a different device is to be used after the initial credentialing proctorship.

Maintenance of Competency for Percutaneous ASD/PFO Closure

To maintain physician proficiency and competency in percutaneous ASD/PFO closure, a minimum of 10 cases per year is recommended. Similarly, to maintain catheterization laboratory proficiency, a minimum of 10 cases per year should be performed in each institution each year. To achieve this experience, it may be necessary to concentrate the procedures in the hands of only a few operators. A multidisciplinary program, including neurology consultation for PFO closure, prospective evaluation of case selection, and evaluation of clinical outcomes is critical to ensure appropriateness and maintain safety and efficacy. Laboratories and individual operators that are not active enough to maintain quality outcomes should reconsider treating these patients.

Quality Assurance

The quality improvement process used for oversight of ASD/PFO closure should include concurrent case review, and will also benefit from regular case conferences to discuss indications, procedural techniques, and case outcomes. It is particu-

Downloaded from circ.ahajournals.org by on August 4, 2008

0295
09/15/08

larly useful in any developing procedural area to share results with other institutions through informal and formal conferences. Because there are, as of yet, no large databases of outcomes for these procedures, participation in local, regional, and national registries is encouraged. Focusing the performance of these procedures in the hands of a few experienced operators is also recommended.

Hypertrophic Cardiomyopathy and Alcohol Septal Ablation

Hypertrophic cardiomyopathy is the most common genetic cardiovascular disease, with a prevalence in the general population estimated to be 0.2% (103). Physicians performing these procedures should have extensive knowledge of the outcomes, limitations and complications of medical therapy (104), dual chamber pacing and surgical myectomy (105–107), and alcohol septal ablation (105–114). No comparative trial against surgical myectomy has been performed.

Criteria for Competency

Acquisition of competence. It is strongly recommended that alcohol septal ablation be offered within a multidisciplinary program that includes the contribution of experienced cardiac surgeons, echocardiographers, general cardiologists, and electrophysiologists. Although there are currently no data regarding the minimum number of procedures required for training and for credentialing, a minimum number of 10 procedures seems to be appropriate.

Maintenance of competence. It is recommended that individual operators perform a minimum of 6 cases per year to maintain competence in performance of septal ablation for hypertrophic cardiomyopathy. Each institution should employ a multidisciplinary program with prospective evaluation of case selection and clinical outcomes. Such an approach is critical for any institution offering alcohol septal ablation as a treatment option for symptomatic patients with hypertrophic obstructive cardiomyopathy.

Quality assurance. Quality assurance in such low-volume procedures requires an approach similar to that outlined for ASD and PFO closures, as previously described.

Valvular Heart Disease

Cognitive Knowledge Base

Physicians performing invasive procedures on stenotic cardiac valves must have extensive knowledge of the pathoanatomy, the hemodynamic alterations, the clinical course, and the outcomes of various therapeutic options. Complications of aortic (115,116) and mitral (117–119) valvuloplasty should be well understood.

Criteria for Competency

Acquisition of competence. Mitral valvuloplasty is one of the most challenging cardiac procedures. The presence of a "learning curve" has been well described (120,121). Thus, training in the performance of mitral valvuloplasty requires the acquisition of clinical skills for the evaluation of indications for the procedure and the assessment of suitable valve morphology. It requires the development of proficiency in the performance of transseptal cardiac catheterization, device manipulation, and online evaluation of hemodynamic parameters. The interventionalist must be able to recognize and manage complications specific to mitral valvuloplasty, including acute mitral regurgitation, cardiac perforation, pericardial tamponade, and stroke. Although a learning curve has been well described, there are currently no specific data regarding the minimum numbers needed for competency. Nonetheless, 5 to 10 cases should be done with an experienced colleague before attempting to perform balloon valvuloplasty independently. Any program offering mitral valvuloplasty as an alternative to mitral valve replacement or surgical commissurotomy for the treatment of mitral stenosis should include a thorough quality assurance program and close monitoring of case selection and clinical outcomes. As with other infrequently performed procedures, concentration of experience among a small subset of interventional cardiologists within an institution is appropriate.

Maintenance of competence. With the low prevalence of mitral stenosis in the United States, maintaining experience is difficult. Given this limitation, concentration of this experience among institutional and perhaps regional centers may be appropriate.

Quality assurance. Quality assurance in such low-volume procedures requires an approach similar to that outlined for ASD and PFO closures, as previously described.

Percutaneous Ventricular Assist Devices

Percutaneous ventricular assist devices are becoming available. They require training and proctored supervision to attain competence, as well as periodic use or refresher drills to maintain competence. As with other seldom-used techniques, experience should be concentrated among a limited number of operators and laboratory staff who have received appropriate training.

Laboratory and Staff Competence

In order for laboratories to become competent in the performance of noncoronary cardiac procedures, the supervising or performing operator should be fully credentialed in the procedure. Initially, this may require off-site training, simulation training, a visiting proctor, or a combination of these approaches. The operator responsible for the performance of the procedure in the catheterization laboratory should supervise the staff in acquiring the necessary skills and equipment for the procedure. As is the case for the operators of lower volume procedures, there should be a small number of dedicated staff members trained to perform specific noncoronary interventions, concentrating the experience. If and when a specific procedure becomes more common, then the training may be expanded to the remainder of the staff and operators.

0296
09/15/08

Conclusions and Recommendations

Percutaneous Noncoronary Interventions

Noncoronary cardiac interventions require special training that is not possible for all operators to obtain because of the small number of these procedures. Therefore, it is necessary to concentrate the activity both in training and practice so that adequate experience can be obtained to allow for quality performance. Hospitals should develop clear credentialing criteria, despite the small number of cases and empiric data from which to judge appropriateness, as well as success and complication rates of these procedures.

The quality improvement process used for oversight of percutaneous noncoronary interventions should include concurrent case review, and will also benefit from regular case conferences to discuss indications, procedural techniques, and case outcomes. It is particularly useful in any developing procedural area to share results with other institutions through informal and formal conferences. Since there are, as of yet, no large databases of outcomes for these procedures, participation in local, regional, and national registries is encouraged. Focusing the performance of these procedures in the hands of a few experienced operators is also recommended.

ACC/AHA/SCAI 2005 Guideline Update for Percutaneous Coronary Intervention—Summary Article

A Report of the American College of Cardiology/American Heart Association Task Force on Practice Guidelines (ACC/AHA/SCAI Writing Committee to Update the 2001 Guidelines for Percutaneous Coronary Intervention)

WRITING COMMITTEE MEMBERS

Sidney C. Smith, Jr, MD, FACC, FAHA, Chair; Ted E. Feldman, MD, FACC, FSCAI*; John W. Hirshfeld, Jr, MD, FACC, FSCAI*; Alice K. Jacobs, MD, FACC, FAHA, FSCAI; Morton J. Kern, MD, FACC, FAHA, FSCAI*; Spencer B. King, III, MD, MACC, FSCAI; Douglass A. Morrison, MD, PhD, FACC, FSCAI*; William W. O'Neill, MD, FACC, FSCAI; Hartzell V. Schaff, MD, FACC, FAHA; Patrick L. Whitlow, MD, FACC, FAHA; David O. Williams, MD, FACC, FAHA, FSCAI

TASK FORCE MEMBERS

Elliott M. Antman, MD, FACC, FAHA, Chair; Sidney C. Smith, Jr, MD, FACC, FAHA, Vice-Chair; Cynthia D. Adams, MSN, APRN-BC, FAHA; Jeffrey L. Anderson, MD, FACC, FAHA; David P. Faxon, MD, FACC, FAHA†; Valentin Fuster, MD, PhD, FACC, FAHA, FESC†; Jonathan L. Halperin, MD, FACC, FAHA; Loren F. Hiratzka, MD, FACC, FAHA†; Sharon Ann Hunt, MD, FACC, FAHA; Alice K. Jacobs, MD, FACC, FAHA; Rick Nishimura, MD, FACC, FAHA; Joseph P. Ornato, MD, FACC, FAHA; Richard L. Page, MD, FACC, FAHA; Barbara Riegel, DNSc, RN, FAHA

The American College of Cardiology/American Heart Association/Society for Cardiovascular Angiography and Interventions (ACC/AHA/SCAI) 2005 Guideline Update for Percutaneous Coronary Intervention (PCI) contains changes in the recommendations, along with supporting text. For the purpose of comparison, this summary contains a list of the updated recommendations (middle column) alongside a list of the 2001 recommendations (left column), with each set accompanied by a comment (right column) that provides the rationale for the changes, additions, or deletions (see Table 1). References

*Official SCAI representative.

†Former Task Force Member during this writing effort.

Acknowledgment: The ACC and AHA recognize Dr J. Ward Kennedy for his dedicated service on developing ACC/AHA guidelines for PTCA and PCI since their inception in 1986 and for his counsel and advice in the preparation of this guideline.

This document was approved by the American College of Cardiology Foundation Board of Trustees in September 2005, by the American Heart Association Science Advisory and Coordinating Committee in September 2005, and by the Society for Cardiovascular Angiography and Interventions in September 2005.

The ACC/AHA Task Force on Practice Guidelines makes every effort to avoid any actual or potential conflicts of interest that might arise as a result of an outside relationship or personal interest of a member of the writing panel. Specifically, all members of the writing panel are asked to provide disclosure statements of all such relationships that might be perceived as real or potential conflicts of interest. These statements are reviewed by the parent task force, reported orally to all members of the writing panel at the first meeting, and updated as changes occur. The relationship with industry information for writing committee members, as well as peer reviewers of the document, is located in an appendix of the full-text guideline, which is available on the ACC, AHA, and SCAI Web sites.

When citing this document, the American Heart Association requests that the following citation format be used: Smith SC Jr, Feldman TE, Hirshfeld JW Jr, Jacobs AK, Kern MJ, King SB III, Morrison DA, O'Neill WW, Schaff HV, Whitlow PL, Williams DO. 0306
09/15/08

that support either the 2001 recommendations that have changed or the new or revised recommendations are cited in parentheses at the end of each recommendation or comment. A list of abbreviations is included in the Appendix. The reader is referred to the full-text guideline posted on the World Wide Web sites of the ACC, the AHA, and the SCAI for a more detailed explanation of the changes discussed here. Please note that we have changed the table of contents headings in the 2001 ACC/AHA Guidelines for Percutaneous Coronary Intervention from roman numerals to unique identifying numbers.

In preparing this update, the committee was guided by the following principles:

1. Changes in recommendations and levels of evidence were made because of the availability of data from new randomized trials, the accumulation of new clinical evidence, and/or the development of clinical consensus.
2. The committee is cognizant of the healthcare, logistic, and financial implications of recent trials and factored in these considerations in arriving at the class level of certain recommendations.
3. All recommendations in the PCI guideline update have been written in full sentences that express a complete thought, such that a recommendation, even if separated and presented apart from the rest of the document, will still convey the full intent of the recommendation.
4. The committee wishes to re-emphasize that the recommendations in the guideline apply to most patients but may require modification by existing situations that only the primary treating healthcare provider can evaluate properly.
5. The committee endeavored to maintain the consistency of recommendations in this and other previously published guidelines, primarily the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction and the ACC/AHA 2002 Guideline Update for the Management of Patients With Non–ST-Elevation Myocardial Infarction.

The classification of recommendations and levels of evidence are expressed in the ACC/AHA format as follows:

Classification of Recommendations

Class I: Conditions for which there is evidence for and/or general agreement that a given procedure or treatment is beneficial, useful, and effective.

Class II: Conditions for which there is conflicting evidence and/or a divergence of opinion about the usefulness/efficacy of a procedure or treatment.

IIa: Weight of evidence/opinion is in favor of usefulness/efficacy.

IIb: Usefulness/efficacy is less well established by evidence/opinion.

Class III: Conditions for which there is evidence and/or general agreement that the procedure/treatment is not useful/effective and in some cases may be harmful.

Level of Evidence

Level of Evidence A: Data derived from multiple randomized clinical trials or meta-analyses.

Level of Evidence B: Data derived from a single randomized trial or nonrandomized studies.

Level of Evidence C: Only consensus opinion of experts, case studies, or standard-of-care.

2001 Recommendation	2005 New or Revised Recommendation	Comments
3. Outcomes		
3.2 Acute Outcome: Procedural Complications		
Class I	**Class I**	
None	All patients who have signs or symptoms suggestive of MI during or after PCI and those with complicated procedures should have CK-MB and troponin I or T measured after the procedure. (*Level of Evidence: B*)	This recommendation appeared in the text of the 2001 revision for CK-MB only. Troponin I or T measurement has been added, and it is now listed as a class I, level of evidence B recommendation (1–10).
Class IIa	**Class IIa**	
None	Routine measurement of cardiac biomarkers (CK-MB and/or troponin I or T) in all patients undergoing PCI is reasonable 8 to 12 hours after the procedure. *(Level of Evidence: C)*	Routine measurement of CK-MB or troponin I or T is added as a new class IIa, level of evidence C recommendation. The committee did not think that evidence regarding the clinical utility of routine measurement of biomarkers in all patients was strong enough to warrant a class I recommendation.
4. Institutional and Operator Competency		
4.1 Quality Assurance		
Class I	**Class I**	
None	1. An institution that performs PCI should establish an ongoing mechanism for valid peer review of its quality and outcomes. Review should be conducted both at the level of the entire program and at the level of the individual practitioner. Quality-assessment reviews should take risk adjustment, statistical power, and national benchmark statistics into consideration. Quality-assessment reviews should include both tabulation of adverse event rates for comparison with benchmark values and case review of complicated procedures and some uncomplicated procedures. *(Level of Evidence: C)*	Quality assurance is an important responsibility for all institutions in which PCI is performed. Institutions must monitor the PCI program with respect to process, appropriateness, and outcomes and correct any circumstances in which quality falls below accepted norms. The quality assessment should be conducted at the level of both the entire program and the individual practitioner.
	2. An institution that performs PCI should participate in a recognized PCI data registry for the purpose of benchmarking its outcomes against current national norms. *(Level of Evidence: C)*	Participation in a recognized PCI registry for benchmarking outcomes against current national norms is an important part of the quality-improvement process. The ACC–National Cardiovascular Data Registry® or other databases may serve as a valuable resource in this regard.
4.2 Operator and Institutional Volume		
Class I	**Class I**	
PCI done by operators with acceptable volume (greater than or equal to 75) at high-volume centers (greater than 400). *(Level of Evidence: B)*	1. Elective PCI should be performed by operators with acceptable annual volume (at least 75 procedures) at high-volume centers (more than 400 procedures) with on-site cardiac surgery. *(Level of Evidence: B)*	Wording has been added to clarify this statement and emphasize that it relates to elective PCI performed at centers with on-site cardiac surgery.
	2. Elective PCI should be performed by operators and institutions whose historical and current risk-adjusted outcomes statistics are comparable to those reported in contemporary national data registries. *(Level of Evidence: C)*	This recommendation was added to emphasize that historical and current risk-adjusted outcomes for operators and institutions are an essential part of the quality-improvement process.
	3. Primary PCI for STEMI should be performed by experienced operators who perform more than 75 elective PCI procedures per year and, ideally, at least 11 PCI procedures for STEMI per year. Ideally, these procedures should be performed in institutions that perform more than 400 elective PCIs per year and more than 36 primary PCI procedures for STEMI per year. *(Level of Evidence: B)*	This recommendation is expanded based on data from the New York State registry indicating that physicians performing more than 10 primary PCI procedures per year have lower mortality rates (11–13).
Class IIa	**Class IIa**	
1. PCI done by operators with acceptable volume (75 or more) at low-volume centers (200–400). *(Level of Evidence: C)*	1. It is reasonable that operators with acceptable volume (at least 75 PCI procedures per year) perform PCI at low-volume centers (200 to 400 PCI procedures per year) with on-site cardiac surgery. *(Level of Evidence: B)*	Wording has been changed to comply with current recommended phrasing for class IIa recommendation. The fact that this recommendation applies to centers with on-site cardiac surgery is emphasized. Level of evidence has been changed to B based on accumulated published evidence (14).

2001 Recommendation	2005 New or Revised Recommendation	Comments
2. PCI done by low-volume operators (fewer than 75) at high-volume centers (more than 400). Note: Ideally operators with an annual procedure volume less than 75 should only work at institutions with an activity level of more than 600 procedures/year.* *(Level of Evidence: C)* *Operators who perform fewer than 75 procedures per year should develop a defined mentoring relationship with a highly experienced operator who has an annual procedural volume of at least 150 procedures per year.	2. It is reasonable that low-volume operators (fewer than 75 PCI procedures per year) perform PCI at high-volume centers (more than 400 PCI procedures per year) with on-site cardiac surgery. Ideally, operators with an annual procedure volume less than 75 should only work at institutions with an activity level of more than 600 procedures per year. Operators who perform fewer than 75 procedures per year should develop a defined mentoring relationship with a highly experienced operator who has an annual procedural volume of at least 150 procedures per year. *(Level of Evidence: B)*	Wording has been changed to comply with current recommended phasing. Level of evidence has been changed to B based on accumulated published evidence (15).
Class IIb	**Class IIb**	
None	The benefit of primary PCI for STEMI patients eligible for fibrinolysis when performed by an operator who performs fewer than 75 procedures per year (or fewer than 11 PCIs for STEMI per year) is not well established. (Level of Evidence: C)	This recommendation has been added to address the issue of low-volume operators performing primary PCI. It reflects the relative lack of evidence supporting a benefit of primary PCI for low-volume operators.
Class III	**Class III**	
PCI done by low-volume operators (fewer than 75) at low-volume centers (200–400). Note: An institution with a volume of fewer than 200 procedures/year, unless in a region that is underserved because of geography, should carefully consider whether it should continue to offer service.* *(Level of Evidence: C)* *Operators who perform fewer than 75 procedures per year should develop a defined mentoring relationship with a highly experienced operator who has an annual procedural volume of at least 150 procedures per year.	It is not recommended that elective PCI be performed by low-volume operators (fewer than 75 procedures per year) at low-volume centers (200 to 400) with or without on-site cardiac surgery. An institution with a volume of fewer than 200 procedures per year, unless in a region that is underserved because of geography, should carefully consider whether it should continue to offer this service. *(Level of Evidence: B)*	Wording has been changed to reflect current preferred phrasing. Level of evidence changed to B on the basis of published data indicating poorer outcomes at low-volume centers (15).
4.3. Role of On-Site Cardiac Surgical Back-up		
Class I	**Class I**	
1. Patients undergoing elective PCI in facilities with on-site cardiac surgery. *(Level of Evidence: B)*	1. Elective PCI should be performed by operators with acceptable annual volume (at least 75 procedures per year) at high-volume centers (more than 400 procedures annually) that provide immediately available on-site emergency cardiac surgical services. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology and volume criteria; otherwise, no significant changes.
2. Patients undergoing primary PCI in facilities with on-site cardiac surgery. *(Level of Evidence: B)*	2. Primary PCI for patients with STEMI should be performed in facilities with on-site cardiac surgery. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology and to be consistent with the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction.
Class III	**Class III**	
Patients undergoing elective PCI in facilities without on-site cardiac surgery. *(Level of Evidence: C)*	Elective PCI should not be performed at institutions that do not provide on-site cardiac surgery.* *(Level of Evidence: C)* *Several centers have reported satisfactory results based on careful case selection with well-defined arrangements for immediate transfer to a surgical program (18–28). A small, but real fraction of patients undergoing elective PCI will experience a life-threatening complication that could be managed with the immediate on-site availability of cardiac surgical support but cannot be managed effectively by urgent transfer. Wennberg et al. found higher mortality in the Medicare database for patients undergoing elective PCI in institutions without onsite cardiac surgery (29). These recommendations may be subject to revision as clinical data and experience increase.	Phrasing has been changed to reflect current terminology. As with many dynamic areas in interventional cardiology, these recommendations may be subject to revision as clinical data and experience increase.

2001 Recommendation	2005 New or Revised Recommendation	Comments
Section 4.4 Primary PCI for STEMI Without On-Site Cardiac Surgery		
Class IIb	**Class IIb**	
Patients undergoing primary PCI in facilities without on-site cardiac surgery, but with a proven plan for rapid access (within 1 h) to a cardiac surgery operating room in a nearby facility with appropriate hemodynamic support capability for transfer. The procedure should be limited to patients with ST-segment elevation MI or new LBBB on ECG, and done in a timely fashion (balloon inflation within 90 plus or minus 30 min of admission) by persons skilled in the procedure (at least 75 PCIs/year) and only at facilities performing a minimum of 36 primary PCI procedures per year. *(Level of Evidence: B)*	Primary PCI for patients with STEMI might be considered in hospitals without on-site cardiac surgery, provided that appropriate planning for program development has been accomplished, including appropriately experienced physician operators (more than 75 total PCIs and, ideally, at least 11 primary PCIs per year for STEMI), an experienced catheterization team on a 24 hours per day, 7 days per week call schedule, and a well-equipped catheterization laboratory with digital imaging equipment, a full array of interventional equipment, and intra-aortic balloon pump capability, and provided that there is a proven plan for rapid transport to a cardiac surgery operating room in a nearby hospital with appropriate hemodynamic support capability for transfer. The procedure should be limited to patients with STEMI or MI with new or presumably new LBBB on ECG and should be performed in a timely fashion (goal of balloon inflation within 90 minutes of presentation) by persons skilled in the procedure (at least 75 PCIs per year) and at hospitals that perform a minimum of 36 primary PCI procedures per year. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology. Recommendations have been added that 1) physicians perform at least 11 primary PCIs per year for STEMI, 2) a 24 hours per day, 7 days per week call schedule be maintained, and 3) the catheterization laboratory be well equipped with digital imaging equipment, a full array of interventional equipment, and intra-aortic balloon pump capability. The intent is to ensure optimal experience availability and capability to perform primary PCI in patients with STEMI (16,17).
Class III	**Class III**	
Patients undergoing primary PCI in facilities without on-site cardiac surgery and without a proven plan for rapid access (within 1 h) to a cardiac surgery operating room in a nearby facility with appropriate hemodynamic support capability for transfer or when performed by lower-skilled operators (fewer than 75 PCIs per year) in a facility performing fewer than 36 primary PCI procedures per year. *(Level of Evidence: C)*	Primary PCI should not be performed in hospitals without on-site cardiac surgery and without a proven plan for rapid transport to a cardiac surgery operating room in a nearby hospital or without appropriate hemodynamic support capability for transfer. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology and to place emphasis on need for inter-institutional planning and support.
4.5 Elective PCI Without On-Site Surgery		
Class III	**Class III**	
Patients undergoing elective PCI in facilities without on-site cardiac surgery. *(Level of Evidence: C)*	Elective PCI should not be performed at institutions that do not provide on-site cardiac surgery. *(Level of Evidence: C)* *Several centers have reported satisfactory results based on careful case selection with well-defined arrangements for immediate transfer to a surgical program (18–28). A small, but real fraction of patients undergoing elective PCI will experience a life-threatening complication that could be managed with the immediate on-site availability of cardiac surgical support but cannot be managed effectively by urgent transfer. Wennberg et al. found higher mortality in the Medicare database for patients undergoing elective PCI in institutions without onsite cardiac surgery (29). These recommendations may be subject to revision as clinical data and experience increase.	Repeated from previous section for consistency. Phrasing has been changed to reflect current terminology.
5.1. Patients With Asymptomatic Ischemia or Canadian Cardiovascular Society (CCS) Class I or II Angina		
Class I	**Class IIa**	
Patients who do not have treated diabetes with asymptomatic ischemia or mild angina with 1 or more significant lesions in 1 or 2 coronary arteries suitable for PCI with a high likelihood of success and a low risk of morbidity and mortality. The vessels to be dilated must subtend a large area of viable myocardium. *(Level of Evidence: B)*	1. PCI is reasonable in patients with asymptomatic ischemia or CCS class I or II angina and with 1 or more significant lesions in 1 or 2 coronary arteries suitable for PCI with a high likelihood of success and a low risk of morbidity and mortality. The vessels to be dilated must subtend a moderate to large area of viable myocardium or be associated with a moderate to severe degree of ischemia on noninvasive testing. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology. This recommendation and all of those that follow in Section 5 have been reworded to be consistent with the CCS classification system of angina. This recommendation has been changed to class IIa to reflect the published data and Writing Committee consensus that not all patients in this clinical category must have PCI performed (30,31).
Class IIa		
1. The same clinical and anatomic requirements for Class I, except the myocardial area at risk is of moderate size or the patient has treated diabetes. *(Level of Evidence: B)*		This recommendation has been merged with other class IIa recommendations of this section, and the phrasing has been changed to reflect current terminology.

2001 Recommendation	2005 New or Revised Recommendation	Comments
	2. PCI is reasonable for patients with asymptomatic ischemia or CCS class I or II angina, and recurrent stenosis after PCI with a large area of viable myocardium or high-risk criteria on noninvasive testing. *(Level of Evidence: C)*	This is a new recommendation dealing with the management of recurrent stenosis after PCI among patients with asymptomatic ischemia or class I or II angina.
	3. Use of PCI is reasonable in patients with asymptomatic ischemia or CCS class I or II angina with significant left main CAD (greater than 50% diameter stenosis) who are candidates for revascularization but are not eligible for CABG. *(Level of Evidence: B)*	This recommendation for PCI among patients who are eligible for CABG who have significant left main disease has been added to reflect the favorable results noted by several trials with PCI (32–35).
Class IIb		
Patients with asymptomatic ischemia or mild angina with greater than or equal to 3 coronary arteries suitable for PCI with a high likelihood of success and a low risk of morbidity and mortality. The vessels to be dilated must subtend at least a moderate area of viable myocardium. In the physician's judgment, there should be evidence of myocardial ischemia by ECG exercise testing, stress nuclear imaging, stress echocardiography or ambulatory ECG monitoring or intracoronary physiologic measurements. *(Level of Evidence: B)*		This recommendation has been eliminated and replaced by the following 2 recommendations. For each, the phrasing has been constructed to reflect current terminology.
	Class IIb	
	1. The effectiveness of PCI for patients with asymptomatic ischemia or CCS class I or II angina who have 2- or 3-vessel disease with significant proximal LAD CAD who are otherwise eligible for CABG with 1 arterial conduit and who have treated diabetes or abnormal LV function is not well established. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology. Among patients who are eligible, CABG with 1 arterial conduit is generally preferred for treatment of multivessel disease with significant proximal LAD obstruction in patients with treated diabetes and/or abnormal LV function (36).
	2. PCI might be considered for patients with asymptomatic ischemia or CCS class I or II angina with nonproximal LAD CAD that subtends a moderate area of viable myocardium and demonstrates ischemia on noninvasive testing. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology. PCI might be considered in this clinical setting.
Class III	**Class III**	
Patients with asymptomatic ischemia or mild angina who do not meet the criteria as listed under Class I or Class II and who have: a. Only a small area of viable myocardium at risk b. No objective evidence of ischemia c. Lesions that have a low likelihood of successful dilatation d. Mild symptoms that are unlikely to be due to myocardial ischemia e. Factors associated with increased risk of morbidity or mortality f. Left main disease g. Insignificant disease less than 50% *(Level of Evidence: C)*	PCI is not recommended in patients with asymptomatic ischemia or CCS class I or II angina who do not meet the criteria as listed under the class II recommendations or who have 1 or more of the following: a. Only a small area of viable myocardium at risk *(Level of Evidence: C)* b. No objective evidence of ischemia *(Level of Evidence: C)* c. Lesions that have a low likelihood of successful dilatation *(Level of Evidence: C)* d. Mild symptoms that are unlikely to be due to myocardial ischemia *(Level of Evidence: C)* e. Factors associated with increased risk of morbidity or mortality *(Level of Evidence: C)* f. Left main disease and eligibility for CABG *(Level of Evidence: C)* g. Insignificant disease (less than 50% coronary stenosis) *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology. Recommendation has been reworded to be consistent with CCS classification system for angina. Level of evidence has been added for each subgroup.
5.2 Patients With CCS Class III Angina		
Class I	**Class IIa**	
Patients with 1 or more significant lesions in 1 or more coronary arteries suitable for PCI with a high likelihood of success and low risk of morbidity or mortality. The vessel(s) to be dilated must subtend a moderate or large area of viable myocardium and have high risk. *(Level of Evidence: B)*	1. It is reasonable that PCI be performed in patients with CCS class III angina and single-vessel or multivessel CAD who are undergoing medical therapy and who have 1 or more significant lesions in 1 or more coronary arteries suitable for PCI with a high likelihood of success and low risk of morbidity or mortality. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology. Recommendation has been reworded to be consistent with CCS classification system for angina. The recommendation class has been changed to IIa to reflect published data and Writing Committee consensus. Criteria regarding viable and high-risk myocardium have been deleted from this recommendation (30, 31).

Downloaded from circ.ahajournals.org by on August 27, 2008

2001 Recommendation	2005 New or Revised Recommendation	Comments
Class IIa		
Patients with focal saphenous vein graft lesions or multiple stenoses who are poor candidates for reoperative surgery. *(Level of Evidence: C)*	2. It is reasonable that PCI be performed in patients with CCS class III angina with single-vessel or multivessel CAD who are undergoing medical therapy with focal saphenous vein graft lesions or multiple stenoses who are poor candidates for reoperative surgery. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology.
	3. Use of PCI is reasonable in patients with CCS class III angina with significant left main CAD (greater than 50% diameter stenosis) who are candidates for revascularization but are not eligible for CABG. *(Level of Evidence: B)*	This recommendation for PCI among patients with significant left main disease who are not eligible for CABG has been added to reflect the favorable results noted by several trials with PCI (32–35).
Class IIb	**Class IIb**	
Patient has 1 or more lesions to be dilated with reduced likelihood of success or the vessel(s) subtend a less than moderate area of viable myocardium. Patients with 2- or 3-vessel disease, with significant proximal LAD CAD and treated diabetes or abnormal LV function. *(Level of Evidence: B)*	1. PCI may be considered in patients with CCS class III angina with single-vessel or multivessel CAD who are undergoing medical therapy and who have 1 or more lesions to be dilated with a reduced likelihood of success. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology. The 2001 recommendation has been split into 2 separate recommendations.
	2. PCI may be considered in patients with CCS class III angina and no evidence of ischemia on noninvasive testing or who are undergoing medical therapy and have 2- or 3-vessel CAD with significant proximal LAD CAD and treated diabetes or abnormal LV function. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology. The use of noninvasive testing to evaluate for evidence of ischemia has been added.
Class III	**Class III**	
Patient has no evidence of myocardial injury or ischemia on objective testing and has not had a trial of medical therapy, or has a. Only a small area of myocardium at risk b. All lesions or the culprit lesion to be dilated with morphology with a low likelihood of success c. A high risk of procedure-related morbidity or mortality. *(Level of Evidence: C)*	PCI is not recommended for patients with CCS class III angina with single-vessel or multivessel CAD, no evidence of myocardial injury or ischemia on objective testing, and no trial of medical therapy, or who have 1 of the following: a. Only a small area of myocardium at risk *(Level of Evidence: C)* b. All lesions or the culprit lesion to be dilated with morphology that conveys a low likelihood of success *(Level of Evidence: C)* c. A high risk of procedure-related morbidity or mortality *(Level of Evidence: C)* d. Insignificant disease (less than 50% coronary stenosis) *(Level of Evidence: C)* e. Significant left main CAD and candidacy for CABG *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology. Class III recommendations #2 and #3 from the 2001 guidelines have been merged into this recommendation.
2. Patients with insignificant coronary stenosis (e.g., less than 50% diameter). *(Level of Evidence: C)*		See above.
3. Patients with significant left main CAD who are candidates for CABG. *(Level of Evidence: B)*		See above.
5.3 Unstable Angina/Non–ST-Elevation Myocardial Infarction (UA/NSTEMI) *(Note: Some of these recommendations have been repeated from above because the sections for the 2005 guideline were revised slightly.)*		
	Class I	
	An early invasive PCI strategy is indicated for patients with UA/NSTEMI who have no serious comorbidity and who have coronary lesions amenable to PCI. Patients must have any of the following high-risk features: a. Recurrent ischemia despite intensive anti-ischemic therapy *(Level of Evidence: A)* b. Elevated troponin level *(Level of Evidence: A)* c. New ST-segment depression *(Level of Evidence: A)* d. CHF symptoms or new or worsening MR *(Level of Evidence: A)* e. Depressed LV systolic function *(Level of Evidence: A)* f. Hemodynamic instability *(Level of Evidence: A)* g. Sustained ventricular tachycardia *(Level of Evidence: A)* h. PCI within 6 months *(Level of Evidence: A)* i. Prior CABG *(Level of Evidence: A)*	Added to maintain consistency with the ACC/AHA 2002 Guideline Update for the Management of Patients With Unstable Angina and Non–ST-Segment Myocardial Infarction (37).

09/15/08

2001 Recommendation	2005 New or Revised Recommendation	Comments
Class IIa	**Class IIa**	
1. Patients with focal saphenous vein graft lesions or multiple stenoses who are poor candidates for reoperative surgery. *(Level of Evidence: C)*	1. It is reasonable that PCI be performed in patients with UA/NSTEMI and single-vessel or multivessel CAD who are undergoing medical therapy with focal saphenous vein graft lesions or multiple stenoses who are poor candidates for reoperative surgery. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology.
	2. In the absence of high-risk features associated with UA/NSTEMI, it is reasonable to perform PCI in patients with amenable lesions and no contraindication for PCI with either an early invasive or early conservative strategy. See full-text guidelines. *(Level of Evidence: B)*	Added in accordance with growing evidence regarding PCI for patients with UA/NSTEMI (30, 37–39).
	3. Use of PCI is reasonable in patients with UA/NSTEMI with significant left main CAD (greater than 50% diameter stenosis) who are candidates for revascularization but are not eligible for CABG. *(Level of Evidence: B)*	Added in accordance with growing evidence regarding PCI for patients with UA/NSTEMI (32–35, 40–43).
	Class IIb	
	1. In the absence of high-risk features associated with UA/NSTEMI, PCI may be considered in patients with single-vessel or multivessel CAD who are undergoing medical therapy and who have 1 or more lesions to be dilated with reduced likelihood of success. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology. Original recommendation replaced by 2 separate recommendations as noted here and in the following recommendations.
	2. PCI may be considered in patients with UA/NSTEMI who are undergoing medical therapy who have 2- or 3-vessel disease, significant proximal LAD CAD, and treated diabetes or abnormal LV function. *(Level of Evidence: B)*	See above.
2. All patients after a non–Q-wave MI. *(Level of Evidence: C)*		This recommendation was removed because it is now covered by the revised recommendations from the ACC/AHA 2002 Guideline Update for the Management of Patients With Unstable Angina and Non–ST-Segment Myocardial Infarction.
Class III	**Class III**	
1. Patient has no evidence of myocardial injury or ischemia on objective testing and has not had a trial of medical therapy, or has a. Only a small area of myocardium at risk b. All lesions or the culprit lesion to be dilated with morphology with a low likelihood of success c. A high risk of procedure-related morbidity or mortality. *(Level of Evidence: C)*	1. In the absence of high-risk features associated with UA/NSTEMI, PCI is not recommended for patients with UA/NSTEMI with single-vessel or multivessel CAD and no trial of medical therapy, or who have 1 or more of the following a. Only a small area of myocardium at risk *(Level of Evidence: C)* b. All lesions or the culprit lesion to be dilated with morphology that conveys a low likelihood of success *(Level of Evidence: C)* c. A high risk of procedure-related morbidity or mortality *(Level of Evidence: C)* d. Insignificant disease (less than 50% coronary stenosis) *(Level of Evidence: C)* e. Significant left main CAD and candidacy for CABG *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology and level of evidence for each subgroup. Class III recommendations #2 and #3 from the 2001 guidelines have been merged into this recommendation.
2. Patients with insignificant coronary stenosis (e.g., less than 50% diameter). *(Level of Evidence: C)*		See above.
3. Patients with significant left main CAD who are candidates for CABG. *(Level of Evidence: B)*		See above.

5.4. Patients With STEMI

The phrasing has been changed to reflect current terminology as needed for all recommendations in this section and to be consistent with the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction.

2001 Recommendation	2005 New or Revised Recommendation	Comments
5.4.1. General and Specific Considerations		
Class I	**Class I**	
1. As an alternative to thrombolytic therapy in patients with AMI and ST-segment elevation or new or presumed new left bundle-branch block who can undergo angioplasty of the infarct artery less than or equal to 12 h from the onset of ischemic symptoms or more than 12 h if symptoms persist, if performed in a timely fashion* by individuals skilled in the procedure† and supported by experienced personnel in an appropriate laboratory environment.‡ *(Level of Evidence: A)* *Performance standard: balloon inflation within 90 plus or minus 30 min of hospital admission. †Individuals who perform 75 or more PCI procedures per year. ‡Centers that perform more than 200 PCI procedures per year and have cardiac surgical capability.	General considerations: 1. If immediately available, primary PCI should be performed in patients with STEMI (including true posterior MI) or MI with new or presumably new LBBB who can undergo PCI of the infarct artery within 12 hours of symptom onset, if performed in a timely fashion (balloon inflation goal within 90 minutes of presentation) by persons skilled in the procedure (individuals who perform more than 75 PCI procedures per year, ideally at least 11 PCIs per year for STEMI). The procedure should be supported by experienced personnel in an appropriate laboratory environment (one that performs more than 200 PCI procedures per year, of which at least 36 are primary PCI for STEMI, and that has cardiac surgery capability). *(Level of Evidence: A)* Primary PCI should be performed as quickly as possible, with a goal of a medical contact–to-balloon or door-to-balloon time within 90 minutes. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology to be consistent with the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction. This revised recommendation reflects the evidence from several trials and a meta-analysis of 23 trials comparing PCI with fibrinolysis that confirm the advantage of PCI. The conditions under which PCI must be performed to optimize this advantage are included in the recommendation (11–13,44–47).
2. In patients who are within 36 h of an acute ST elevation/Q-wave or new left bundle-branch block MI who develop cardiogenic shock, are less than 75 years of age, and revascularization can be performed within 18 h of the onset of shock by individuals skilled in the procedure† and supported by experienced personnel in an appropriate laboratory environment.‡ *(Level of Evidence: A)* †Individuals who perform 75 or more PCI procedures per year. ‡Centers that perform more than 200 PCI procedures per year and have cardiac surgical capability (193, 194).	Specific considerations: 2. Primary PCI should be performed for patients less than 75 years old with ST elevation or presumably new LBBB who develop shock within 36 hours of MI and are suitable for revascularization that can be performed within 18 hours of shock, unless further support is futile because of the patient's wishes or contraindications/unsuitability for further invasive care. *(Level of Evidence: A)*	Phrasing has been changed to reflect current terminology. The changes from the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction have been included in this recommendation (48–53).
	3. Primary PCI should be performed in patients with severe HF and/or pulmonary edema (Killip class 3) and onset of symptoms within 12 hours. The medical contact–to-balloon or door-to-balloon time should be as short as possible (i.e., goal within 90 minutes). *(Level of Evidence: B)*	The changes from the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction are included in this new recommendation, which emphasizes the benefits of PCI for patients with severe CHF and onset of symptoms within 12 hours (54–56).
	Class IIa	
	1. Primary PCI is reasonable for selected patients 75 years or older with ST elevation or LBBB or who develop shock within 36 hours of MI and are suitable for revascularization that can be performed within 18 hours of shock. Patients with good prior functional status who are suitable for revascularization and agree to invasive care may be selected for such an invasive strategy. *(Level of Evidence: B)*	This recommendation, which addresses the benefit of PCI in patients at least 75 years of age with shock, is included from the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction with phrasing to reflect current terminology (48–53).
	2. It is reasonable to perform primary PCI for patients with onset of symptoms within the prior 12 to 24 hours and 1 or more of the following: a. Severe HF *(Level of Evidence: C)* b. Hemodynamic or electrical instability *(Level of Evidence: C)* c. Evidence of persistent ischemia *(Level of Evidence: C)*	This new recommendation provides guidance for use of primary PCI within 12 to 24 hours of symptom onset in certain patient subsets. Phrasing has been changed to reflect current terminology and to be consistent with the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction.

2001 Recommendation	2005 New or Revised Recommendation	Comments
Class III	**Class III**	
1. Elective PCI of a non–infarct-related artery at the time of acute MI. *(Level of Evidence: C)*	1. Elective PCI should not be performed in a non–infarct-related artery at the time of primary PCI of the infarct-related artery in patients without hemodynamic compromise. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology. Important phrasing has been added to address the issue of PCI of the non–infarct-related coronary artery at the time of primary PCI.
2. In patients with acute MI who: a. have received fibrinolytic therapy within 12 h and have no symptoms of myocardial ischemia b. are eligible for thrombolytic therapy and are undergoing primary angioplasty by an inexperienced operator (individual who performs fewer than 75 PCI procedures per year) c. are beyond 12 h after onset of symptoms and have no evidence of myocardial ischemia. *(Level of Evidence: C)*	2. Primary PCI should not be performed in asymptomatic patients more than 12 hours after onset of STEMI who are hemodynamically and electrically stable. *(Level of Evidence: C)* **Class IIb** 1. The benefit of primary PCI for STEMI patients eligible for fibrinolysis when performed by an operator who performs fewer than 75 PCI procedures per year (or fewer than 11 PCIs for STEMI per year) is not well established. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology. Recommendation has been divided to emphasize specific points. The class IIb recommendation was upgraded in the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction and approved by the PCI Writing Committee.
5.4.2. PCI in Fibrinolytic-Ineligible Patients		
Class IIa	**Class I**	
As a reperfusion strategy in candidates who have a contraindication to thrombolytic therapy. *(Level of Evidence: C)*	Primary PCI should be performed in fibrinolytic-ineligible patients who present with STEMI within 12 hours of symptom onset. *(Level of Evidence: C)*	Revised recommendation reflects the committee's opinion that primary PCI should be a class I recommendation for fibrinolytic-ineligible patients within 12 hours of symptom onset. Phrasing has been changed to reflect current terminology and to be consistent with the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction.
	Class IIa	
	It is reasonable to perform primary PCI for fibrinolytic-ineligible patients with onset of symptoms within the prior 12 to 24 hours and 1 or more of the following: a. Severe HF *(Level of Evidence: C)* b. Hemodynamic or electrical instability *(Level of Evidence: C)* c. Evidence of persistent ischemia *(Level of Evidence: C)*	New recommendation from the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction that addresses conditions under which primary PCI is reasonable for fibrinolytic-ineligible patients with onset of symptoms within the prior 12 to 24 hours.
5.4.3. Facilitated PCI		
Class IIb	**Class IIb**	
None	Facilitated PCI might be performed as a reperfusion strategy in higher-risk patients when PCI is not immediately available and bleeding risk is low. *(Level of Evidence: B)*	New recommendation from the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction addressing conditions for which facilitated PCI might be considered. Important randomized trials are under way, and more data are needed regarding outcomes resulting from this treatment strategy (57–63).
5.4.4. PCI After Failed Fibrinolysis (Rescue PCI)		
Class I	**Class I**	
None	1. Rescue PCI should be performed in patients less than 75 years old with ST elevation or LBBB who develop shock within 36 hours of MI and are suitable for revascularization that can be performed within 18 hours of shock, unless further support is futile because of the patient's wishes or contraindications/unsuitability for further invasive care. *(Level of Evidence: B)*	See above (49,51).
	2. Rescue PCI should be performed in patients with severe HF and/or pulmonary edema (Killip class 3) and onset of symptoms within 12 hours. *(Level of Evidence: B)*	See above (54–56).

Downloaded from circ.ahajournals.org by on August 27, 2008

0315
09/15/08

2001 Recommendation	2005 New or Revised Recommendation	Comments
Class IIa	**Class IIa**	
None	1. Rescue PCI is reasonable for selected patients 75 years or older with ST elevation or LBBB or who develop shock within 36 hours of MI and are suitable for revascularization that can be performed within 18 hours of shock. Patients with good prior functional status who are suitable for revascularization and agree to invasive care may be selected for such an invasive strategy. *(Level of Evidence: B)*	See above (49).
	2. It is reasonable to perform rescue PCI for patients with 1 or more of the following: a. Hemodynamic or electrical instability *(Level of Evidence: C)* b. Evidence of persistent ischemia. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology.
Class IIb		
Recurrent angina without objective evidence of ischemia/infarction. *(Level of Evidence: C)*		Deleted. Recurrent angina is not applicable to rescue angioplasty. Recurrent symptoms are discussed elsewhere.
Class III	**Class III**	
Routine PTCA within 48 h following failed thrombolysis. *(Level of Evidence: B)*	Rescue PCI in the absence of 1 or more of the above class I or IIa indications is not recommended. *(Level of Evidence: C)*	Evidence obtained from studies of PTCA during the fibrinolytic era before the use of stents failed to show a benefit for reperfusion under these conditions. Current trials are under way to investigate the outcome of PCI with stent placement among patients with occluded arteries days after presentation with STEMI.
5.4.5. PCI After Successful Fibrinolysis or for Patients Not Undergoing Primary Reperfusion		
Class I	**Class I**	
1. Objective evidence for recurrent infarction or ischemia (rescue PCI). *(Level of Evidence: B)*	1. In patients whose anatomy is suitable, PCI should be performed when there is objective evidence of recurrent MI. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology. Revised to a level of evidence C.
2. Spontaneous or provocable myocardial ischemia during recovery from infarction. *(Level of Evidence: C)*	2. In patients whose anatomy is suitable, PCI should be performed for moderate or severe spontaneous or provocable myocardial ischemia during recovery from STEMI. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology. Level of evidence revised on the basis of review by the Writing Committee (64).
3. Persistent hemodynamic instability. *(Level of Evidence: C)*	3. In patients whose anatomy is suitable, PCI should be performed for cardiogenic shock or hemodynamic instability. See also Section 5.4.6 of the full-text guidelines. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology. Level of evidence was revised on the basis of review by the Writing Committee, and cardiogenic shock has been added (cardiogenic shock is discussed in Section 5.4.6 and is a class I, level of evidence A recommendation for patients younger than 75 years old and a class IIa, level of evidence B recommendation for those aged 75 years and older) (49).
Class IIa	**Class IIa**	
Patients with LV ejection fraction less than or equal to 0.4, CHF, or serious ventricular arrhythmias. *(Level of Evidence: C)*	1. It is reasonable to perform routine PCI in patients with LV ejection fraction less than or equal to 0.40, CHF, or serious ventricular arrhythmias. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology.
Class IIb		
1. Coronary angiography and angioplasty for an occluded infarct-related artery in an otherwise stable patient to revascularize that artery (open artery hypothesis). *(Level of Evidence: C)*		Recommendation deleted. Important trials are under way to provide evidence regarding outcomes associated with or resulting from this therapy.
2. Angioplasty of the infarct-related artery stenosis within hours to days (48 h) following successful thrombolytic therapy in asymptomatic patients without clinical and/or inducible evidence of ischemia. *(Level of Evidence: B)*		This recommendation has been merged into the upgraded class IIb recommendation for PCI after fibrinolytic therapy below.

Downloaded from circ.ahajournals.org by on August 27, 2008

0316
09/15/08

2001 Recommendation	2005 New or Revised Recommendation	Comments
	Class IIa	
3. Clinical HF during the acute episode, but subsequent demonstration of preserved LV function (LV ejection fraction greater than 0.4). *(Level of Evidence: C)*	2. It is reasonable to perform PCI when there is documented clinical heart failure during the acute episode, even though subsequent evaluation shows preserved LV function (LV ejection fraction greater than 0.40). *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology. Recommendation was upgraded to class IIa by the Writing Committee.
Class III	**Class III**	
1. PCI of the infarct-related artery within 48 to 72 h after thrombolytic therapy without evidence of spontaneous or provocable ischemia. *(Level of Evidence: C)*		This recommendation has been upgraded and merged into the IIb recommendation for PCI after fibrinolytic therapy below.
	Class IIb	
2. Routine PCI of the infarct-artery stenosis immediately after thrombolytic therapy. *(Level of Evidence: A)*	1. PCI might be considered as part of an invasive strategy after fibrinolytic therapy. *(Level of Evidence: C)*	This recommendation has been upgraded to class IIb to reflect a possible benefit from improved technology. The Committee recognizes the potential benefit of this therapy but believes more data are needed to define outcomes of PCI after fibrinolytic therapy in the current era of improved antiplatelet, anticoagulant, and drug-eluting stent therapies.
5.4.6. PCI for Cardiogenic Shock		
Class I	**Class I**	
None	Primary PCI is recommended for patients less than 75 years old with ST elevation or LBBB who develop shock within 36 hours of MI and are suitable for revascularization that can be performed within 18 hours of shock, unless further support is futile because of the patient's wishes or contraindications/unsuitability for further invasive care. *(Level of Evidence: A)*	Phrasing has been changed to reflect current terminology and the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction (48–53).
Class IIa	**Class IIa**	
Cardiogenic shock or hemodynamic instability. *(Level of Evidence: B)*	Primary PCI is reasonable for selected patients 75 years or older with ST elevation or LBBB who develop shock within 36 hours of MI and are suitable for revascularization that can be performed within 18 hours of shock. Patients with good prior functional status who are suitable for revascularization and agree to invasive care may be selected for such an invasive strategy. *(Level of Evidence: B)*	Phrasing has been changed to reflect current technology and modified to be consistent with the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction (48–53).
5.5. Percutaneous Intervention in Patients With Prior Coronary Bypass Surgery		
Class I	**Class I**	
Patients with early ischemia (usually within 30 days) after CABG (194). *(Level of Evidence: B)*	1. When technically feasible, PCI should be performed in patients with early ischemia (usually within 30 days) after CABG. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology.
	2. It is recommended that distal embolic protection devices be used when technically feasible in patients undergoing PCI to saphenous vein grafts. *(Level of Evidence: B)*	New recommendation is based on several studies demonstrating efficacy of distal embolic protection devices in PCI to saphenous vein grafts (65,66).
Class IIa	**Class IIa**	
1. Patients with ischemia occurring 1 to 3 years postoperatively and preserved LV function with discrete lesions in graft conduits. *(Level of Evidence: B)*	1. PCI is reasonable in patients with ischemia that occurs 1 to 3 years after CABG and who have preserved LV function with discrete lesions in graft conduits. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology.
2. Disabling angina secondary to new disease in a native coronary circulation. (If angina is not typical, the objective evidence of ischemia should be obtained.) *(Level of Evidence: B)*	2. PCI is reasonable in patients with disabling angina secondary to new disease in a native coronary circulation after CABG. (If angina is not typical, objective evidence of ischemia should be obtained.) *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology.
3. Patients with diseased vein grafts more than 3 years following CABG. *(Level of Evidence: B)*	3. PCI is reasonable in patients with diseased vein grafts more than 3 years after CABG. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology.
	4. PCI is reasonable when technically feasible in patients with a patent left internal mammary artery graft who have clinically significant obstructions in other vessels. *(Level of Evidence: C)*	This new recommendation addresses the feasibility of PCI to native circulation in the presence of a patent left internal mammary artery graft.

Downloaded from circ.ahajournals.org by on August 27, 2008

0317
09/15/08

2001 Recommendation	2005 New or Revised Recommendation	Comments
Class III	**Class III**	
1. PCI to chronic total vein graft occlusions. *(Level of Evidence: B)*	1. PCI is not recommended in patients with prior CABG for chronic total vein graft occlusions. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology.
2. Patients with multivessel disease, failure or multiple SVGs, and impaired LV function. *(Level of Evidence: B)*	2. PCI is not recommended in patients who have multiple target lesions with prior CABG and who have multivessel disease, failure of multiple SVGs, and impaired LV function unless repeat CABG poses excessive risk due to severe comorbid conditions. *(Level of Evidence: B)*	Phrasing has been changed to reflect current technology, and considerations regarding risk of repeat CABG have been added (36).
5.6.1. Intravascular Ultrasound Imaging (IVUS)		
Class IIa	**Class IIa**	
1. Assessment of the adequacy of deployment of coronary stents, including the extent of stent apposition and determination of the minimum luminal diameter within the stent. *(Level of Evidence: B)* 2. Determination of the mechanism of stent restenosis (inadequate expansion vs. neointimal proliferation) and to enable selection of appropriate therapy (plaque ablation vs. repeat balloon expansion). *(Level of Evidence: B)* 3. Evaluation of coronary obstruction at a location difficult to image by angiography in a patient with a suspected flow-limiting stenosis. *(Level of Evidence: C)*	1. IVUS is reasonable for the following: a. Assessment of the adequacy of deployment of coronary stents, including the extent of stent apposition and determination of the minimum luminal diameter within the stent. *(Level of Evidence: B)* b. Determination of the mechanism of stent restenosis (inadequate expansion versus neointimal proliferation) and to enable selection of appropriate therapy (vascular brachytherapy versus repeat balloon expansion). *(Level of Evidence: B)* c. Evaluation of coronary obstruction at a location difficult to image by angiography in a patient with a suspected flow-limiting stenosis. *(Level of Evidence: C)* d. Assessment of a suboptimal angiographic result after PCI. *(Level of Evidence: C)* e. Establishment of the presence and distribution of coronary calcium in patients for whom adjunctive rotational atherectomy is contemplated. *(Level of Evidence: C)* f. Determination of plaque location and circumferential distribution for guidance of directional coronary atherectomy. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology. The previous class IIa recommendations for IVUS have been listed together in the recommendation rather than separately, with the exception that the Writing Committee has changed the recommendation to evaluate coronary disease after transplantation to class IIb.
4. Assessment of a suboptimal angiographic result following PCI. *(Level of Evidence: C)* 5. Diagnosis and management of coronary disease following cardiac transplantation. *(Level of Evidence: C)* 6. Establish presence and distribution of coronary calcium in patients for whom adjunctive rotational atherectomy is contemplated. *(Level of Evidence: C)* 7. Determination of plaque location and circumferential distribution for guidance of directional coronary atherectomy. *(Level of Evidence: B)*		
Class IIb	**Class IIb**	
1. Determine extent of atherosclerosis in patients with characteristic anginal symptoms and a positive functional study with no focal stenoses or mild CAD on angiography. *(Level of Evidence: C)* 2. Preinterventional assessment of lesional characteristics and vessel dimensions as a means to select an optimal revascularization device. *(Level of Evidence: C)*	IVUS may be considered for the following: a. Determination of the extent of atherosclerosis in patients with characteristic anginal symptoms and a positive functional study with no focal stenoses or mild CAD on angiography. *(Level of Evidence: C)* b. Preinterventional assessment of lesional characteristics and vessel dimensions as a means to select an optimal revascularization device. *(Level of Evidence: C)* c. Diagnosis of coronary disease after cardiac transplantation. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology. The previous class IIb recommendations for IVUS have been listed together in this recommendation rather than separately. The use of IVUS to evaluate coronary disease in transplant patients is now a class IIb recommendation.
Class III	**Class III**	
When angiographic diagnosis is clear and no interventional treatment is planned. *(Level of Evidence: C)*	IVUS is not recommended when the angiographic diagnosis is clear and no interventional treatment is planned. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology.

2001 Recommendation	2005 New or Revised Recommendation	Comments
5.6.2. Coronary Artery Pressure and Flow: Use of Fractional Flow Reserve and Coronary Vasodilatory Reserve		
Class IIa	**Class IIa**	
Assessment of the physiological effects of intermediate coronary stenoses (30 to 70% luminal narrowing) in patients with anginal symptoms. Coronary pressure or Doppler velocimetry may also be useful as an alternative to performing noninvasive functional testing (e.g., when the functional study is absent or ambiguous) to determine whether an intervention is warranted. *(Level of Evidence: B)*	It is reasonable to use intracoronary physiologic measurements (Doppler ultrasound, fractional flow reserve) in the assessment of the effects of intermediate coronary stenoses (30% to 70% luminal narrowing) in patients with anginal symptoms. Coronary pressure or Doppler velocimetry may also be useful as an alternative to performing noninvasive functional testing (e.g., when the functional study is absent or ambiguous) to determine whether an intervention is warranted. *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology.
Class IIb	**Class IIb**	
1. Evaluation of the success of percutaneous coronary revascularization in restoring flow reserve and to predict the risk of restenosis. *(Level of Evidence: C)*	1. Intracoronary physiologic measurements may be considered for the evaluation of the success of PCI in restoring flow reserve and to predict the risk of restenosis. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology.
2. Evaluation of patients with anginal symptoms without an apparent angiographic culprit lesion. *(Level of Evidence: C)*	2. Intracoronary physiologic measurements may be considered for the evaluation of patients with anginal symptoms without an apparent angiographic culprit lesion. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology.
Class III	**Class III**	
Routine assessment of the severity of angiographic disease in patients with a positive, unequivocal noninvasive functional study. *(Level of Evidence: C)*	Routine assessment with intracoronary physiologic measurements such as Doppler ultrasound or fractional flow reserve to assess the severity of angiographic disease in patients with a positive, unequivocal noninvasive functional study is not recommended. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology.
6. Management of Patients Undergoing PCI **6.1. Evolution of Technologies** **6.1.1. Acute Results**		
	Class I	
	It is recommended that distal embolic protection devices be used when technically feasible in patients undergoing PCI to saphenous vein grafts. *(Level of Evidence: B)*	Published clinical trials using distal embolic protection devices confirm their benefit in improving cardiovascular outcomes among patients undergoing PCI to saphenous vein grafts (65,66).
6.2. Antiplatelet and Antithrombotic Adjunctive Therapies for PCI **6.2.1. Oral Antiplatelet Therapy**		
	Class I	
The recommendations in this section appeared in table format in the 2001 guideline (see 2001 Table). The phrasing has been changed to reflect current terminology and to be consistent with new evidence and/or recommendations in the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction and the ACC/AHA 2002 Guideline Update for Patients With Unstable Angina/Non–ST-Elevation Myocardial Infarction.	1. Patients already taking daily chronic aspirin therapy should take 75 to 325 mg of aspirin before the PCI procedure is performed. *(Level of Evidence: A)*	A daily dose of 75 mg of aspirin has been shown to result in improved cardiovascular outcomes similar to daily doses of 325 mg but with fewer bleeding complications (67–69).
	2. Patients not already taking daily chronic aspirin therapy should be given 300 to 325 mg of aspirin at least 2 hours and preferably 24 hours before the PCI procedure is performed. *(Level of Evidence: C)*	Higher doses of aspirin are recommended for patients not already taking aspirin therapy immediately before PCI procedures.
	3. After the PCI procedure, in patients with neither aspirin resistance, allergy, nor increased risk of bleeding, aspirin 325 mg daily should be given for at least 1 month after bare-metal stent implantation, 3 months after sirolimus-eluting stent implantation, and 6 months after paclitaxel-eluting stent implantation, after which daily chronic aspirin use should be continued indefinitely at a dose of 75 to 162 mg. *(Level of Evidence: B)*	The doses and duration of aspirin therapy recommended herein are derived from those used for US Food and Drug Administration approval of the specific stent types noted in the recommendation. Daily chronic aspirin therapy is based on recommendations in the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction and evidence indicating that aspirin therapy in dosages as low as 75 mg per day yields outcomes similar to those achieved with 325 mg per day but with fewer side effects (67,69–71).

09/15/08

2001 Recommendation	2005 New or Revised Recommendation	Comments
	4. A loading dose of clopidogrel should be administered before PCI is performed. *(Level of Evidence: A)* An oral loading dose of 300 mg, administered at least 6 hours before the procedure, has the best established evidence of efficacy. *(Level of Evidence: B)*	Clopidogrel is an important adjunctive therapy for patients undergoing PCI with stent placement. The best evidence of efficacy exists for 300 mg given at least 6 hours before PCI is performed (68,69,72).
	5. In patients who have undergone PCI, clopidogrel 75 mg daily should be given for at least 1 month after bare-metal stent implantation (unless the patient is at increased risk for bleeding; then it should be given for a minimum of 2 weeks), 3 months after sirolimus stent implantation, and 6 months after paclitaxel stent implantation, and ideally up to 12 months in patients who are not at high risk of bleeding. *(Level of Evidence: B)*	Clopidogrel therapy in the dosage of 75 mg daily should be given after stent placement to all patients. The duration of therapy varies for each stent and is based on data from clinical trials used for US Food and Drug Administration approval of that stent (67,69–71).
	Class IIa	
	1. If clopidogrel is given at the time of procedure, supplementation with GP IIb/IIIa receptor antagonists can be beneficial to facilitate earlier platelet inhibition than with clopidogrel alone. *(Level of Evidence: B)*	When clopidogrel is given at the time of a PCI procedure, supplementation with glycoprotein IIb/IIIa receptor antagonists can be beneficial, especially among high-risk patients (73,74).
	2. For patients with an absolute contraindication to aspirin, it is reasonable to give a 300-mg loading dose of clopidogrel, administered at least 6 hours before PCI, and/or GP IIb/IIIa antagonists, administered at the time of PCI. *(Level of Evidence: C)*	A significant number of patients will have resistance to aspirin. The strongest evidence for clopidogrel benefit exists for doses of 300 mg given at least 6 hours before the procedure.
	3. When a loading dose of clopidogrel is administered, a regimen of greater than 300 mg is reasonable to achieve higher levels of antiplatelet activity more rapidly, but the efficacy and safety compared with a 300-mg loading dose are less established. *(Level of Evidence: C)*	Many patients receive clopidogrel therapy at the time of PCI in dosages greater than 600 mg. Although more pronounced inhibition of platelet function has been demonstrated for doses of clopidogrel greater than 300 mg, the safety of these higher doses and their benefits on clinical outcome are not fully established.
	4. It is reasonable that patients undergoing brachytherapy be given daily clopidogrel 75 mg indefinitely and daily aspirin 75 to 325 mg indefinitely unless there is significant risk for bleeding. *(Level of Evidence: C)*	Subacute or later thrombosis has been observed in patients undergoing brachytherapy, and for this reason long-term antiplatelet therapy is recommended.
	Class IIb	
	In patients in whom subacute thrombosis may be catastrophic or lethal (unprotected left main, bifurcating left main, or last patent coronary vessel), platelet aggregation studies may be considered and the dose of clopidogrel increased to 150 mg per day if less than 50% inhibition of platelet aggregation is demonstrated. *(Level of Evidence: C)*	Clopidogrel resistance is a significant problem, and owing to its contribution to catastrophic clinical outcomes, the Writing Committee recommends studies be performed with increases in clopidogrel dose being recommended for use in those with higher-risk lesions.
6.2.2 Glycoprotein IIb/IIIa Inhibitors		
	Class I	
The recommendations in this section appeared in table format in the 2001 guideline (see 2001 Table). The phrasing has been changed to reflect current terminology and to be consistent with new evidence and/or recommendations in the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction and the ACC/AHA 2002 Guideline Update for the Management of Patients With Unstable Angina/ Non–ST-Elevation Myocardial Infarction.	In patients with UA/NSTEMI undergoing PCI without clopidogrel administration, a GP IIb/IIIa inhibitor (abciximab, eptifibatide, or tirofiban) should be administered. *(Level of Evidence: A)*§ §It is acceptable to administer the GP IIb/IIIa inhibitor before performance of the diagnostic angiogram ("upstream treatment") or just before PCI ("in-lab treatment").	This recommendation and phrasing are compatible with the ACC/AHA 2002 Guideline Update for the Management of Patients With Unstable Angina and Non–ST-Segment Myocardial Infarction and current evidence from randomized clinical trials. The benefits of GP IIb/IIIa inhibition are especially efficacious when clopidogrel is not given (37).
	Class IIa	
	1. In patients with UA/NSTEMI undergoing PCI with clopidogrel administration, it is reasonable to administer a GP IIb/IIIa inhibitor (abciximab, eptifibatide, or tirofiban). *(Level of Evidence: B)*§ §It is acceptable to administer the GP IIb/IIIa inhibitor before performance of the diagnostic angiogram ("upstream treatment") or just before PCI ("in-lab treatment").	See above (37).
	2. In patients with STEMI undergoing PCI, it is reasonable to administer abciximab as early as possible. *(Level of Evidence: B)*	Recommendation has been added for consistency with the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction (57,75–78).

2001 Recommendation	2005 New or Revised Recommendation	Comments
	3. In patients undergoing elective PCI with stent placement, it is reasonable to administer a GP IIb/IIIa inhibitor (abciximab, eptifibatide, or tirofiban). *(Level of Evidence: B)*	Phrasing has been changed to reflect current terminology, especially in a high-risk patient (79,80).
	Class IIb	
	In patients with STEMI undergoing PCI, treatment with eptifibatide or tirofiban may be considered. *(Level of Evidence: C)*	Recommendation has been added for consistency with the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction.
6.2.3. Antithrombotic Therapy		
6.2.3.1 Unfractionated Heparin, Low-Molecular-Weight Heparin, and Bivalirudin		
	Class I	
The recommendations in this section appeared in table format in the 2001 guideline (see 2001 Table). The phrasing has been changed to reflect current terminology and to be consistent with new evidence and/or recommendations in the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction and the ACC/AHA 2002 Guideline Update for the Management of Patients With Unstable Angina/Non–ST-Elevation Myocardial Infarction.	1. Unfractionated heparin should be administered to patients undergoing PCI. *(Level of Evidence: C)*	Phrasing has been changed to reflect current terminology.
	2. For patients with heparin-induced thrombocytopenia, it is recommended that bivalirudin or argatroban be used to replace heparin. *(Level of Evidence: B)*	Bivalirudin and argatroban are established therapies in place of heparin among patients with heparin-induced thrombocytopenia (81, 82).
Class IIa	**Class IIa**	
None	1. It is reasonable to use bivalirudin as an alternative to unfractionated heparin and glycoprotein IIb/IIIa antagonists in low-risk patients undergoing elective PCI. *(Level of Evidence: B)*	New recommendation is based on data from a clinical trial (REPLACE-2) indicating bivalirudin is an acceptable alternative to heparin and GP IIb/IIIa antagonists in low-risk patients undergoing PCI (83).
	2. Low-molecular-weight heparin is a reasonable alternative to unfractionated heparin in patients with UA/NSTEMI undergoing PCI. *(Level of Evidence: B)*	Recommendation from the ACC/AHA 2002 Guideline Update for the Management of Patients With Unstable Angina and Non–ST-Segment Myocardial Infarction has been approved by this Writing Committee and included in these guidelines for consistency.
Class IIb	**Class IIb**	
None	Low-molecular-weight heparin may be considered as an alternative to unfractionated heparin in patients with STEMI undergoing PCI. *(Level of Evidence: B)*	Recommendation from the ACC/AHA Guidelines for the Management of Patients With ST-Elevation Myocardial Infarction has been approved by this Writing Committee and included in these guidelines for consistency.
6.3.4. Left Main CAD		
Class IIa	**Class IIa**	
None	It is reasonable that patients undergoing PCI to unprotected left main coronary obstructions be followed up with coronary angiography between 2 and 6 months after PCI. *(Level of Evidence: C)*	Patients undergoing PCI to an unprotected left main coronary artery are at higher risk for adverse events and should be monitored carefully. On the basis of experience and opinion in the available reports, the Writing Committee recommends angiography be performed between 2 and 6 months after PCI.
7.3.3. Management Strategies for Restenosis After PTCA		
Class IIa	**Class IIa**	
None	It is reasonable to consider that patients who develop restenosis after PTCA or PTCA with atheroablative devices are candidates for repeat coronary intervention with intracoronary stents if anatomic factors are appropriate. *(Level of Evidence: B)*	This new recommendation reflects data indicating a significant reduction in target-lesion revascularization and restenosis for patients undergoing bare-metal stent placement compared with PTCA for restenosis after PTCA (84).
7.3.5. Drug-Eluting Stents		
Class I	**Class I**	
None	A drug-eluting stent should be considered as an alternative to the bare-metal stent in subsets of patients in whom trial data suggest efficacy. *(Level of Evidence: A)*	New recommendation since the 2001 ACC/AHA Guidelines for Percutaneous Coronary Intervention. Evidence continues to accumulate that supports the use of drug-eluting stents (DES) versus bare-metal stents in certain subsets in which DES results and outcomes are better (70, 71, 85–97).
Class IIb	**Class IIb**	
None	A drug-eluting stent may be considered for use in anatomic settings in which the usefulness, effectiveness, and safety have not been fully documented in published trials. *(Level of Evidence: C)*	The data that a DES can improve clinical outcomes for PCI are generally strong. However, DESs have not undergone evaluation for use in all clinical situations and anatomic settings.

2001 Recommendation	2005 New or Revised Recommendation	Comments
7.3.6.2 Drug-Eluting Stents for the Management of In-Stent Restenosis		
Class IIa None	**Class IIa** It is reasonable to perform repeat PCI for in-stent restenosis with a DES or a new DES for patients who develop in-stent restenosis if anatomic factors are appropriate. *(Level of Evidence: B)*	This is a new recommendation. Clinical trials comparing sirolimus and paclitaxel DESs with PTCA for in-stent restenosis demonstrate improved outcomes for the DESs (97–101).
7.3.6.3. Radiation for Restenosis		
Class IIa None	**Class IIa** Brachytherapy can be useful as a safe and effective treatment for in-stent restenosis. *(Level of Evidence: A)*	This is a new recommendation since the 2001 ACC/AHA Guidelines for Percutaneous Coronary Intervention based on evidence supporting the efficacy of brachytherapy in the treatment of in-stent restenosis (102–109).

2001 TABLE. Recommendations for Pharmacological Management of Patients Undergoing PCI—For Comparison Purposes Only (Deleted From 2005 Guideline)

	Clinical Status				
		Transmural Myocardial Infarction			
Drugs	Class I Angina	Class II–IV Angina, Unstable Angina, NSTEMI	Acute Phase MI	After Thrombolysis	Hospital Management Phase
Aspirin	I*	I	I	I	I
Ticlopidine, Clopidogrel†	I‡	I	I	I	I§
Warfarin‖	III‖	III	III	II	I¶
GP blockers#	II	I	II	I	III
Abciximab					
Tirofiban					
Eptifibatide					
Unfractionated heparin**	I	I	I	II	III††

Note: This table has been deleted from the 2005 PCI Guideline Update. The recommendations in this table were updated or deleted, as determined by the writing committee, and included in the 2005 PCI Guideline Update in the recommendation list.

*Roman numerals indicate ACC/AHA class indication I, II, or III.
†In conjunction with stenting.
‡To be given 24–48 h before planned stenting, if possible.
§For 2 to 4 weeks after stent placement.
¶For patients without atrial fibrillation or other pre-existing clinical indications.
‖For patients with anterior myocardial wall motion abnormalities or LV thrombus.
#Every indication may not apply to all individual agents.
**Low-molecular-weight heparin is under investigation to replace unfractionated heparin.
††Other noncoronary thrombotic complications (eg, thrombophlebitis).

Appendix. Abbreviations

CABG	coronary artery bypass graft surgery
CAD	coronary artery disease
CK	creatine kinase
DES	drug-eluting stent
ECG	electrocardiogram
GP	glycoprotein
HF	heart failure
IVUS	intravascular ultrasound
LAD	left anterior descending artery
LBBB	left bundle-branch block
LV	left ventricular
MB	cardiac muscle isoenzyme of creatine kinase
MI	myocardial infarction
MR	mitral regurgitation
NSTEMI	non–ST-elevation myocardial infarction
PCI	percutaneous coronary intervention
STEMI	ST-elevation myocardial infarction
UA	unstable angina

Executive Summary

The Society of Thoracic Surgeons established a Quality Measurement Task Force to develop a methodology for the comprehensive assessment of adult cardiac surgery quality of care, including both individual measures and an overall *composite quality score*. In Part 1 of a two-part series, the Task Force describes the conceptual framework, principles, and guidelines used to select and categorize the individual measures that comprise the composite score.

Quality indicators were selected using the following principles:

1. Quality assessment should be at the level of the program or hospital rather than the individual surgeon.
2. Initial quality reports should focus on coronary artery bypass grafting surgery.
3. Quality measures should be chosen from among those endorsed by the National Quality Forum.
4. Quality measure selection should be consistent with the principles and criteria recommended in the 2006 Institute of Medicine report *Performance Measurement: Accelerating Improvement.*
5. Quality measures should be available as data elements within The Society of Thoracic Surgeons National Adult Cardiac Surgery Database.
6. Quality scores should consider structure, process, and outcomes.
7. Quality scores should assess three temporal domains—preoperative, operative, and postoperative.
8. Quality scores should satisfy multiple criteria for validity.
9. Quality scores should be interpretable and actionable by providers.

Eleven individual measures of coronary artery bypass grafting quality within four domains were selected:

1. *Perioperative Medical Care,* a process bundle of four medications including preoperative β-blockade and discharge aspirin, β-blockade, and lipid-lowering agents.
2. *Operative Care,* a single process measure—use of at least one internal mammary artery.
3. *Risk-Adjusted Operative Mortality.*
4. *Postoperative Risk-Adjusted Major Morbidity,* defined as the risk-adjusted occurrence of any of the following: renal failure, deep sternal wound infection, reexploration, stroke, or prolonged ventilation/intubation.

In summary, The Society of Thoracic Surgeons Quality Measurement Task Force has selected a group of measures to serve as the basis for comprehensive assessment of adult cardiac surgery quality. Part 2 of this report describes the statistical considerations relevant to combining these measures into composite scores, then using such scores as the basis for a provider rating system.

Introduction

Performance measurement is an essential element of quality improvement initiatives and health care reform [1]. For two decades, cardiac surgeons have systematically collected and analyzed outcomes data in order to continually enhance the quality of care they deliver. Central to this effort was the development of The Society of Thoracic Surgeons National Adult Cardiac Surgery Database (STS NCD), which is the largest and most comprehensive single-specialty clinical database in health care. Through this resource, information is available on all aspects of adult cardiac procedures including preoperative patient characteristics, operative management, perioperative care, postoperative outcomes, and discharge medications and venue.

These data are used in numerous ways to improve selection, operative techniques, and perioperative care of cardiac surgical patients. Over the past decade, analysis of such risk-adjusted data has also been used by providers, health policy researchers, payers, and government agencies to assess the quality of cardiac surgical care. Until recently, these efforts were focused on the short-term outcomes (eg, operative mortality and morbidity) of cardiac surgery, particularly coronary artery bypass grafting (CABG) [2–4]. However, it is now recognized that such clinical outcomes are only one measure of overall health care quality. More comprehensive quality indicators are desirable, including intraoperative processes of care as well as perioperative measures that impact hospital outcomes, secondary prevention, and long-term health.

Continuing its tradition of leadership in efforts to assess and improve quality, The Society of Thoracic Surgeons recently established a Quality Measurement Task Force (QMTF) consisting of clinical, health policy, and statistical experts. Its charge is to develop methodologies to assess the overall quality of care delivered by cardiac surgery providers (used generically in these reports to refer to hospitals or cardiac surgical groups that participate in the STS NCD). Such information could serve several important functions: (1) to provide public accountability, a fundamental responsibility of any professional organization; (2) to facilitate quality improvement activities; and (3) to satisfy the reporting requirements of various pay for performance programs.

Commercial organizations, accrediting, and governmental agencies have previously developed cardiac surgery rating systems; however, most of these were designed without the involvement or endorsement of cardiac surgeons. Furthermore, all are based on administrative data with the exception of several state report cards (eg, New York, Massachusetts), and the latter have been limited primarily to operative outcomes. The goal of the QMTF is to develop a more *comprehensive* set of measures based on clinical data elements that have already received the endorsement of the National Quality Forum. With the widespread support of the provider community as well as broad external endorsement, it is expected that these measures could become the standard, benchmark methodology for assessing adult cardiac surgery quality.

The design of such comprehensive quality measures involved clinical, health policy, and statistical considerations. Part 1 of this report outlines the conceptual framework within which the QMTF conducted its deliberations and the guidelines used to select and categorize a comprehensive set of quality measures. Part 2 will describe the statistical considerations relevant to combining these measures into composite scores and subsequently using these scores as the basis for a provider rating system. It also presents the results of a pilot study of the proposed QMTF methodology using actual 2004 data from the STS NCD.

The Concept of Quality

Quality is an abstract construct that cannot be directly measured. In the nomenclature of modern measurement theory, it is characterized by one or more latent (unobserved) variables or traits. The overt, observable manifestations of such underlying traits may be intuitively apparent at the extremes, but difficult to quantify over the broad range between extremes. Different observers may agree that a luxury automobile is high quality, and that an entry-level automobile is of lower quality. However, what are the characteristics that permit this classification to be made, and how is it possible to scale these defining characteristics, weight their relative importance, and combine them into meaningful overall scores?

To quantify abstract constructs like quality, intelligence, or musical ability, we typically rely upon some combination or composite of measurable surrogates that are thought to be associated with or contribute to that underlying trait. For example, to assess intelligence it might be useful to objectively measure visual spatial ability, critical reasoning, and problem-solving approaches, and then assign a score to each area as well as a composite overall score. Ideally, it should also be possible to validate this score against some end point that is believed to be the product of intelligence, such as academic achievement.

Quality is a major focus of American medicine, but how best to define this elusive concept for health care is particularly challenging. At a minimum, any proposed measures of provider quality should be associated with the results we would expect from excellent health care; for example, fewer hospital admissions for chronic diseases, and improved long-term survival. In current practice, quality is often characterized by some combination of *structure, process,* and *outcome* measures, a triad first proposed by Professor Avedis Donabedian at the University of Michigan. Birkmeyer and associates [5] suggest that the suitability of structure, process, or outcome measures to assess quality for a particular procedure is a function of both the potential for adverse consequences and the frequency with which the procedure is performed. For many surgical procedures and medical conditions, small sample sizes [6] or lack of serious adverse sequelae diminish the utility of statistical outcomes com-

0328
09/15/08

parisons, and in such instances process or structural measures may be more appropriate. In contrast, the evaluation of CABG quality is less subject to such limitations. This procedure has important, quantifiable end points and is performed with sufficient frequency to justify the evaluation of outcomes, as well as the more widely applicable process and structural measures.

Structure

Structural measures refer to inherent characteristics of the provider that are believed to be associated with higher quality. These may include, for example, the volume of a particular type of procedure performed annually, advanced information technology such as electronic health records or computerized order entry, participation in an outcomes database registry, sophisticated radiographic imaging capabilities, number of approved residencies, and nurse staffing ratios. For many such measures, the strength of their relationship with desired health care outcomes is not well defined.

Without question, volume is the most extensively studied structural measure of quality in all of medicine and surgery. Whether this reflects "practice makes perfect" or "selective referral" to institutions perceived to be of higher quality is uncertain. The strength of the volume-outcome relationship varies widely. For complex procedures such as esophagectomy or pancreatectomy that are performed relatively infrequently even at high-volume institutions, the volume-outcome association is strong [7]. For some frequently performed, relatively standardized and mature complex procedures such as CABG, where annual hospital volumes may range from 100 to more than 1000 cases, the volume-outcome relationship is weak [3, 7–10].

Structural measures may be useful proxies for outcomes when the latter data are unavailable. Conversely, their relative utility diminishes when reliable outcomes data are accessible. Furthermore, structural measures are often not readily actionable by providers, and this diminishes their usefulness as quality improvement tools.

Process

Process measures reflect the extent to which a provider complies with evidence-based care guidelines. Ideally, use of process measures should be shown to correlate directly with outcomes of care, although only a limited number of such measures meet this criterion (Table 1). In the acute care setting, appropriate process measures might include the administration of aspirin and β-blockade to reduce mortality in acute coronary syndromes, as well as "door to balloon" time for acute myocardial infarction. For chronic disease management, process measures include the degree of compliance with desirable practices such as frequent determination of hemoglobin A1c levels to optimize glycemic control. Evidence-based practice guidelines have been developed by professional organizations with the goal of decreasing practice variation and defining best-practice standards of care [11].

Process measures are particularly useful for procedures and medical conditions in which outcome measures are unavailable or impractical [3, 5, 6]. They have the advantage of being actionable by providers, and they are the dominant quality metric utilized in many pay-for-performance initiatives. Concern exists, however, that when payment depends on compliance with particular process measures, providers may focus on maximizing their performance in these specific areas. In some cases, this may be a perverse incentive, leading to tests or interventions that are unnecessary, costly, or inconsistent with the patient's wishes [12]. It may also focus attention on a few measured processes that comprise only a small fraction of overall care for a particular patient or condition, perhaps to the neglect of other important care measures.

Table 1. Classes of Recommendation and Levels of Evidence

Classes of Recommendation	
Class 1	Intervention is useful and effective
Class 2a	Weight of evidence/opinion favors utility/effectiveness
Class 2b	Usefulness/efficacy less well established by evidence/opinion
Class 3	Intervention is not useful/effective and is potentially harmful
Levels of Evidence	
A	Multiple randomized trials with large numbers of patients
B	Limited number of randomized trials with smaller number of patients, careful analysis of non-randomized studies, or observational registries
C	Expert consensus

In addition to such theoretical concerns, measurement of compliance with process measures also presents practical difficulties. Many patients have legitimate contraindications to a particular measure, such as the use of β-blockade in patients with significant heart block. Ideally, process measure compliance should reflect the number of *eligible* patients who received the treatment or therapy. In practice, agreement about what constitutes a legitimate exclusion has often been difficult even for expert panels, and mechanisms to document such exclusions are both problematic and susceptible to gaming. Many patients are ineligible for some or all of the process measures relevant to their condition, and the number of patients available for assessing provider practice is correspondingly reduced. Even for eligible patients, the proportion of outcome variability explained by adherence to process guidelines may be small [13].

Outcomes

Outcomes are the most obvious, intuitive, and historically used measures of quality. They also represent the quality metric that is generally most important to patients. Although known primarily as the founder of modern nursing practice, Florence Nightingale was in fact a highly regarded epidemiologist and statistician in the latter half of the 19th century [14–16]. Her careful

Downloaded from ats.ctsnetjournals.org by on August 4, 2008

0329
09/15/08

recording of British military deaths in Crimea, and her subsequent report to the government, had a profound impact on the care of wounded soldiers and is one of the earliest practical examples of epidemiologic outcomes analysis. Nightingale also introduced the concept of risk adjustment, which is central to modern profiling efforts.

Unquestionably the most important, seminal contribution to the study of surgical outcomes was that of Ernest Amory Codman, a Boston surgeon who advocated the methodical reporting of both short-term and long-term results. Although on the staff of the Massachusetts General Hospital, Dr Codman began his own hospital that was dedicated to the practical application of these principles. His obsession with quality was neither shared nor appreciated by many of his contemporaries, perhaps partly because of the often brusque fashion with which he presented his views. Nonetheless, his efforts contributed substantially to the development of what ultimately became the American College of Surgeons and the Joint Commission on the Accreditation of Healthcare Organizations [16–19].

It was near the end of the 20th century before the next attempt to quantify health care outcomes on a large scale occurred. The Health Care Financing Administration (HCFA), now known as The Centers for Medicare & Medicaid Services (CMS), publicly released hospital mortality data for all institutions that received payment from HCFA. Because of serious deficiencies with this program, including lack of risk adjustment and the use of an administrative database not designed for outcomes analysis, the program was abandoned shortly after its inception. However, a number of specialty organizations concluded that properly executed data collection and analysis could be a powerful tool to assess and improve quality. In the late 1980s, the STS began development of what subsequently became the NCD [20]. This is currently the largest single specialty clinical database in the world, with entries on more than 3 million surgical procedures from more than 780 cardiac surgery practices. Statistical models have been developed for risk-adjusted mortality and morbidity, and the database also includes substantial information on process measures such as the use of the internal mammary artery (IMA) and of recommended medications such as β-blockers, aspirin, and antilipid agents [4].

Cardiac Surgery Quality

Cardiac surgeons were early adopters of data collection, measurement, and analysis. Their dominant procedure, CABG, is the most commonly performed of all complex operations. It is costly and has broad implications for population health. CABG surgery is the paradigm for outcome measurement given both its frequency and its potential for serious morbidity and mortality.

In recognition of its important public health implications, the National Quality Forum (NQF) recently convened a Cardiac Surgery Performance Measures Steering Committee and associated Technical Advisory Panel, both of which included representatives of the STS, payers, regulators, health policy experts, and consumers. Their charge was to identify and endorse a set of evidence-based measures that would accurately reflect the performance of cardiac surgery programs. Ultimately, a set of 21 structure, process, and outcomes measures were selected (Table 2). It is expected that various subsets or combinations of these measures will become the basis for regional and national quality monitoring and improvement efforts in cardiac surgery. With the exception of those measures pertaining to preoperative antibiotic administration, timing, and duration, the remaining measures are directly related to data elements included in the STS NCD, which further emphasizes the central importance of this instrument.

Table 2. National Quality Forum Voluntary Consensus Standards for Cardiac Surgery

1. Participation in a systematic database for cardiac surgery
2. Surgical volume for isolated coronary artery bypass graft (CABG) surgery, valve surgery, and CABG + valve surgery
3. Timing of antibiotic administration for cardiac surgery patients
4. Selection of antibiotic administration for cardiac surgery patients
5. Preoperative β-blockade
6. Use of internal mammary artery
7. Duration of prophylaxis for cardiac surgery patients
8. Prolonged intubation
9. Deep sternal wound infection rate
10. Stroke/cerebrovascular accident rate
11. Postoperative renal insufficiency rate
12. Surgical reexploration rate
13. Antiplatelet medications at discharge
14. β-Blockade at discharge
15. Antilipid treatment at discharge
16. Risk-adjusted inpatient operative mortality for CABG
17. Risk-adjusted operative mortality for CABG
18. Risk-adjusted operative mortality for aortic valve replacement (AVR)
19. Risk-adjusted operative mortality for mitral valve replacement (MVR)
20. Risk-adjusted operative mortality for MVR + CABG
21. Risk-adjusted operative mortality for AVR + CABG

Principles for Measure Selection

After extensive investigation and discussion, the QMTF established the following principles for the development of a comprehensive quality rating system for cardiac surgery:

1. *Initial public quality reports should focus on programs, not individual surgeons.* Although a number of states, notably New York and Pennsylvania, publish surgeon-specific results, this continues to be a highly controversial topic. Performance reports on individual practitioners are fraught with even more vexing conceptual and technical concerns than reports on hospitals. The potential for unintended negative consequences is greater, leading many experts to recommend caution regarding their use [2, 21, 22].

Downloaded from ats.ctsnetjournals.org by on August 4, 2008

0330
09/15/08

Cardiac surgery is fundamentally a team endeavor, and publicly releasing information on just one element of that team detracts from the more important goals of improving overall team coordination, standardization of care, and clinical effectiveness. Surgeon report cards also focus attention on the one member of the team who ultimately decides which patients to accept for surgery, and this increases the potential for risk aversion. Hospitals do not decide which patients are acceptable risks for surgery—surgeons ultimately bear this responsibility alone. The inevitably higher mortality associated with surgery on high-risk populations will be diluted within the overall results of a hospital or practice group. In contrast, a few such patients may have a substantial negative impact on the results of an individual surgeon. Research indicates that when individual surgeon results are made public, surgeons become more risk averse because they fear the impact of a bad result on their public report card [2, 23, 24]. This may result in denial of care to the very group of high-risk patients who would potentially benefit most from surgery [2, 25, 26].

From a practical standpoint, sample size is also an issue and generally requires accumulating data during a period of 2 to 3 years. The resulting reports include some data that may be as much as 4 years old after the appropriate audit, validation, and analysis have been performed, and some believe this limits their relevance. Some have advocated aggregating data across several measures of individual practitioner performance as a way to mitigate this problem.

Because of the many serious and unresolved concerns regarding this issue, as well as specific prohibitions included in existing STS NCD Participation Agreements, the STS currently does not publicly release information on individual practitioners. It should be noted that alternative approaches to practitioner-level public reporting do exist. For example, it is possible to collect and analyze individual practitioner data confidentially and to have such data reviewed by a committee of experts including clinicians, statisticians, and health policy experts.

2. *Initial quality reports should focus on CABG.* Coronary artery bypass grafting is the most commonly performed and studied of all cardiac surgical procedures. It is relatively standardized, and it has a broad range of well-defined major and minor adverse outcomes, including death. Results for this procedure have become the benchmark by which overall adult cardiac surgery performance is assessed by consumers, regulators, and payers. It should be noted, however, that excellent risk models and data exist for valve surgery as well [27–29]. Early evidence suggests that the results for such procedures may have greater variability among programs than those for CABG, making them a likely focus for subsequent quality profiling.

3. *All measures should be derived from the set of 21 NQF-endorsed adult cardiac surgery measures.* The NQF is a private, not-for-profit organization established in 1999. Its mission is to develop and endorse standardized health care performance measures to provide public accountability, support quality improvement efforts, promote patient safety, and to serve as the basis for pay-for-performance programs and value-based purchasing. The NQF has quickly achieved national respect and credibility because of the extensive process undertaken before any candidate quality measure is endorsed, as well as the diverse constituencies included on its panels. These include providers, payers, consumers, accrediting agencies, and health policy experts. NQF-endorsed measures are widely accepted by both payers and government agencies, and they have legal status as national voluntary consensus standards.

   The NQF has published a set of National Voluntary Consensus Standards for Cardiac Surgery that includes 21 structure, process, and outcome measures (Table 2), all of which are consistent with the Institute of Medicine goals for health care: safe, effective, patient-centered, timely, efficient, and equitable. These measures have thus become *the* set of nationally recognized parameters for assessing quality in cardiac surgery. Use of some combination of these NQF-endorsed measures largely mitigates concerns about their selection or appropriateness and also maximizes the acceptability of the measure to all constituencies.

4. *Measure selection should be consistent with the principles and criteria recommended by the Institute of Medicine.* In its two previous landmark studies, *To Err is Human* [30] and *Crossing the Quality Chasm* [31], the Institute of Medicine established the improvement of health care quality as a major national priority. In its 2006 publication *Performance Measurement: Accelerating Improvement* [1], the Institute of Medicine proposes principles and criteria for the selection of measures by which quality may be assessed. These recommendations include comprehensive; evidence-based; longitudinal; supportive of multiple uses and stakeholders; intrinsic to the care process; providing opportunity for patient input; patient-level, population-based, and systems-level measurement; acknowledgement of shared accountability; a learning system, continually evaluating performance and advancing knowledge; independent and sustainable; scientifically sound (reliable, valid, and explicit); feasible; having important health implications; and aligned with existing leading measure sets [1].

   These guidelines will undoubtedly become the national benchmark by which to evaluate quality

Downloaded from ats.ctsnetjournals.org by on August 4, 2008

0331
09/15/08

and performance measures. Accordingly, the QMTF assessed all its proposed measures to assure compliance with pertinent Institute of Medicine recommendations.

5. *Measures should be readily accessible from the STS NCD instrument.* With the exception of those related to perioperative antibiotics, the NQF-endorsed cardiac surgery measures are based upon or may be derived from data in the STS NCD. The STS NCD is the largest, single-specialty clinical database in the world and is administered by the highly respected Duke Clinical Research Institute. It has unquestioned credibility among providers, payers, and regulators. As a clinical database, it is clearly superior in accuracy to the administrative databases used as the basis for many government and commercial report cards [32, 33].

   Nationally, more than 780 hospitals or adult cardiac surgery practices devote extensive time and resources to the accurate collection of STS NCD data elements. It is both desirable and more efficient to develop quality measures from these existing elements without necessitating any separate work process or substantial additional resources. Consistent with its longstanding practice, the STS will modify the NCD as necessary to meet the evolving needs for additional information.

   As the STS NCD becomes the basis for quality reports to governmental agencies, payers, referring physicians, and the public, it will be crucial to assure the accuracy and validity of these data. Although preliminary reports [34] are encouraging, the STS has nevertheless embarked upon a major auditing initiative to confirm these findings. Undoubtedly such efforts will continue to evolve, hopefully with additional external funding.

6. *Quality assessment should consider, either separately or as a composite, each of Donabedian's three domains of quality—structure, process, and outcomes.* This quality triad is widely accepted in health care, and measures from all three domains are available from the STS NCD. The actual method of presenting scores from individual domains—separately, as a roll-up composite score, or both—has statistical implications that are discussed in Part 2 of this report. Furthermore, the specific report format can be tailored to particular constituencies.

7. *Quality scores should assess all three relevant temporal domains of the cardiac surgical experience—preoperative, operative, and postoperative (including long-term) care.* Preparation for surgery, conduct of the surgical procedure, postoperative morbidity and mortality, and discharge protocols are all important aspects of the surgical experience. Often, they involve different personnel because cardiac surgery is the quintessential team endeavor. An appropriate comprehensive quality measure should have representation from each of these periods of care. The only time frame that currently is difficult to study is long term, but with better information systems and electronic health records, this too will become an important component of quality scores. Our quality measures begin to address this long-term perspective by including discharge medications that primarily impact secondary prevention (aspirin, β-blockade, lipid-lowering agents). The time of hospital discharge after CABG may be one of the most effective opportunities to institute such therapy [35].

8. *Quality scores should satisfy multiple criteria for validity.* Quality scores must be acceptable to both providers, who are being evaluated, and to payers, accrediting agencies, and regulators. The measures should have *face validity* (the measures appear reasonable for their intended purpose), *content validity* (the selected measures encompass all relevant aspects of the concept that is being measured), *construct validity* (the measures accurately reflect the construct they are designed to measure), and *attributional validity* (risk-adjusted outcome measures adequately compensate for patient factors, so that they reflect quality of care and not case mix) [15, 36].

9. *Quality scores should be interpretable and actionable by providers.* The goal is a transparent, clearly defined methodology whose results provide some understanding of a provider's (hospital or program) performance relative to that of other providers. Reporting options would include actual numerical scores, a three-star or five-star rating system, performance tiers with upper and lower bands as currently employed in the CMS Premier Demonstration Project, or statistical techniques that determine with high probability that a given provider's results differ from the performance of its peers.

   Quality scores should enable providers to enact changes that will improve both their scores and, more importantly, the actual quality of care delivered to their patients. In addition to their overall composite score and rating, providers should also receive scores for the four domains and the eleven individual measures, thus enabling them to better focus their quality improvement efforts.

   As will be discussed in Part 2 of this report, the QMTF investigated a number of sophisticated statistical methodologies, including approaches derived from modern psychometric or measurement theory (eg, latent variable analysis, item response theory). Unless such methodologies had unequivocally superior scientific justification for our application, or proved to have superior performance when applied to STS data in pilot studies, we chose to use simpler and more intuitive approaches.

Table 3. The Society of Thoracic Surgeons Quality Measures

1. Perioperative Medical Care (All or None Process Bundle)
   a. Preoperative β-blockade
   b. Discharge aspirin
   c. Discharge β-blockade
   d. Discharge antilipid therapy
2. Operative Care (Process)
   a. Use of at least one internal mammary artery
3. Risk-Adjusted Operative Mortality
4. Postoperative Morbidity: Absence of Any Serious Complication
   a. Renal insufficiency
   b. Deep sternal wound infection
   c. Re-exploration for any cause
   d. Stroke
   e. Prolonged ventilation/intubation

Specific Measure Selection

In addition to these nine major principles, the QMTF also considered evolving new trends in health care quality assessment, including the use of bundled measures and "all or none" scoring as advocated by the Institute for Healthcare Improvement and the Institute of Medicine [1, 37]. Consider a bundle of care measures for a particular condition, such as acute myocardial infarction. If experts agree that all components of this bundle (eg, aspirin after acute myocardial infarction, β-blockade, 90-minute door-to-balloon time, statin on discharge) are important for optimal patient care, then the desired benchmark performance is compliance with *all* components. Failure to achieve one component of the bundle results in no credit. Partial credit not only sets too low a goal but also requires subjective decisions about how to weight the various components of the bundle.

Although the all or none approach in essence assigns equal weights to each component of the bundle, it is preferable to regard them as a group of important measures that are *all* essential to providing the highest quality care. By analogy, it would be impossible to weight the relative importance of the heart, kidneys, and liver to the human body. They all perform quite different tasks but all must work in concert for optimal bodily function. Significant failure of any one of these organs is potentially fatal.

The QMTF ultimately chose eleven individual quality measures grouped within four domains (Table 3). This includes all relevant CABG process and outcomes measures currently endorsed by the NQF. Because of the credibility of the NQF process, we did not conduct additional statistical analyses to determine whether any of these measures could be eliminated, although subsequent pilot studies did not demonstrate substantial correlation among these measures. This suggests that they provide complementary rather than redundant information.

Several of these domains were scored using the all or none principle or, in the case of complications, the corresponding "any or none" principle:

1. *Perioperative Medical Care Process Measure:* All or none compliance with the use of four specific medications (preoperative β-blockade and postoperative aspirin, β-blockade, and lipid-lowering therapy) shown to be associated with improved short or long-term outcomes for CABG patients. These are typically ordered by the surgical care team (staff and resident physicians, physician assistants, nurse practitioners) or cardiologists, often through the use of standardized order sheets.
2. *Operative Process Measure:* Use of the IMA, the single most important and universally accepted process measure in CABG surgery.
3. *Risk-Adjusted Operative Mortality:* The most important outcomes measure, and one for which CABG surgery is particularly well suited because of its frequency and the availability of excellent risk models.
4. *Postoperative Risk-Adjusted Major Morbidity:* Serious complications can be devastating for patients and costly for payers. The STS QMTF morbidity measure is the risk-adjusted rate of patient discharge from a given institution with any of the following five major complications: stroke, deep sternal wound infection, reexploration for any cause, prolonged intubation/ventilation, or renal insufficiency. Definitions of these five morbidities are available from the STS and NQF Websites [38, 39].

The following describes the QMTF rationale for selection of these measures and for the rejection of several others, in the context of the principles established previously.

Perioperative Medical Care

To assess preoperative and postoperative medical care, four NQF-endorsed process measures were selected, all of which are included as data elements in the STS NCD. These include preoperative β-blockade and postoperative aspirin, β-blockade, and lipid-lowering therapy. All these measures are supported by extensive studies, either specifically pertaining to CABG surgery or to the secondary prevention of disease progression in patients with established coronary atherosclerosis [40–45]. Each measure is also included in the 2006 American College of Cardiology (ACC)/American Heart Association (AHA) Guidelines for Secondary Prevention for Patients with Coronary and Other Atherosclerotic Vascular Disease [46].

The QMTF discussed the problem of legitimate exclusions to process measures, as noted previously. Two options for dealing with such exclusions were considered. Ideally, a full list of acceptable exclusions would be agreed upon, included in the STS NCD instrument, and documented as present by the provider when appropriate; however, how to make such an approach operational proved to be problematic. There were concerns regarding what constituted legitimate exclusions and how to prevent gaming of such exclusions. The second option, which we chose, is to assume that the percentage of

Downloaded from ats.ctsnetjournals.org by on August 4, 2008

0333
09/15/08

patients with legitimate exclusions to each process measure should not vary substantially among programs (in contrast to case mix, which can be quite variable). Accordingly, consistent with current NQF specifications, only a few exclusions are recognized for these medical process measures and for the operative process and postoperative outcome measures. The three discharge medication measures are calculated only among patients who survive until hospital discharge; the IMA measure excludes patients undergoing repeat CABG surgery; and the permanent stroke measure excludes patients with a previous cerebrovascular accident.

Because of this limited number of recognized exclusions, all programs will fall short of 100% compliance with the entire bundle of perioperative measures for all patients, but no program should be disproportionately disadvantaged. In a pilot study of data from more than 500 STS NCD participants (Part 2 of this report), application of this all or none approach to perioperative process measures produced a variable and relatively symmetric distribution of compliance percentages. Given that each of these 4 medical process measures was deemed by the QMTF to be efficacious and important for the care of CABG patients, it is noteworthy that current all or none compliance rates vary substantially among STS NCD participant programs. Hence, there is significant room for process improvement. Furthermore, none of these measures would require any additional funding or resources by institutions. They require only the will to change, a standardized order set, and an audit mechanism.

Operative Care

For a surgical procedure regarded as being relatively standardized, operative processes of care for CABG vary widely among cardiac surgery programs. For many of these processes, there is no generally accepted gold standard. Examples of such practice variation include: on-pump versus off-pump CABG; conduct of cardiopulmonary bypass including temperature, hematocrit, flow rates, anticoagulation management, and the use of heparin-bonded circuits; hemostatic and antiinflammatory adjuncts such as aprotinin; single aortic cross clamp versus side clamp; and cardioplegia composition, temperature, and route of administration. For many of these areas, it would be difficult to select a performance benchmark that had broad support, and that could be implemented by most programs without substantially altering otherwise successful operative protocols. This could have the potential for producing significant unintended negative consequences.

We chose not to base our operative quality measure on such indicators that are often a matter of individual preference. However, there is one measure of CABG operative process quality—use of single or multiple IMA—whose importance has been universally recognized for well over two decades [47, 48]. There may be no other single surgical measure that so positively impacts the long-term survival of CABG patients, and it is for this reason that use of at least one IMA was chosen as the operative process measure. Consistent with the NQF definition, exclusion is permitted for repeat CABG procedures.

Risk-Adjusted Operative Mortality

This is the most familiar and widely used of all quality measurements [2], and it has broad acceptance as a valid measure among providers, regulators, and payers. We use the NQF operative mortality definition adapted from the STS NCD. It includes all deaths occurring in-hospital, regardless of timing, as well as all deaths occurring within 30 days of surgery regardless of venue, unless clearly unrelated to the operation.

Postoperative Risk-Adjusted Major Morbidity

Studies by Hannan [49] and Silber [50] and their colleagues suggest that complications and readmissions, which are delayed complications, may measure different aspects of care than does mortality. Furthermore, the same serious complication may result in death at one institution because of "failure to rescue," whereas superior care at another institution may result in patient salvage. For all these reasons, we chose to include a bundle of NQF morbidity measures as a separate outcomes domain in addition to operative mortality.

Patients, providers, and payers have a common goal after CABG surgery—discharge from the hospital alive, and without the occurrence of *any* serious postoperative complication. We selected five postoperative complications from the NQF cardiac surgery measure set (Table 2), all of which are derived from and defined by the STS NCD. These include stroke, renal insufficiency, deep sternal wound infection, reexploration for any cause, and prolonged intubation/ventilation. There are several NQF-approved exclusions for renal failure, stroke, and prolonged ventilation. Because absence of all such complications is the desired outcome, they are again considered as a bundle, in this case any or none. If even one major complication occurs, no credit is received for the bundle. A hierarchical risk model is developed using this dichotomous morbidity measure (1 = presence of *any* of the five major complications, 0 = no major complications) as the dependent variable, and an adjusted any or none morbidity rate is determined (see Part 2 and Technical Appendix).

Measures Considered but Not Included

Two structural measures (database participation and procedural volume) are included in the NQF cardiac surgery measure set but were not specifically chosen for inclusion in our quality score. As all our chosen measures will be derived from the STS NCD, participation in this database will be required for all programs that are rated, and thus this structural measure is included de facto. The other NQF-endorsed structural measure is procedural volume. Based on the studies cited previously, the volume-outcome relationship for CABG is weak. Furthermore, volume is most useful as a surrogate for outcome when accurate determination of the latter is impractical. In the case of CABG, we have highly credible, direct

Downloaded from ats.ctsnetjournals.org by on August 4, 2008

0334
09/15/08

measures of both risk-adjusted mortality and morbidity. For all these reasons, we have chosen not to include volume as a structural measure.

Three NQF cardiac surgery process measures deal with the selection of appropriate preoperative antibiotics, their timing of administration, and duration of use. Because these are not currently included in the STS NCD, they were not selected for our quality measure set. In addition, compliance with these measures is already being closely monitored through multiple other quality measurement and improvement initiatives (eg, Surgical Infection Prevention Project, Surgical Care Improvement Project, American College of Surgeons National Surgical Quality Improvement Program, Joint Commission on Accreditation of Healthcare Organizations).

Finally, although the ACC/AHA endorses the use of angiotensin-converting enzyme inhibitors or angiotensin-receptor blockers for secondary prevention of atherosclerotic coronary disease [46], they are not NQF-endorsed and are therefore not included in our measure set.

Conclusion

The QMTF selected a set of 11 individual quality measures within four domains of care. These are nationally recognized metrics that are also consistent with the guiding principles established by the STS QMTF. This measure set will be the foundation for a comprehensive, composite quality scoring methodology for cardiac surgery. The QMTF envisions this as a dynamic process that will undergo progressive refinements over time.

Part 2 of this report describes the statistical considerations for analyzing and combining these measures and for using the resulting composite scores to characterize provider performance [51].

GUIDELINES FOR STANDARDS IN CARDIAC SURGERY

The following statement is an updated version of guidelines that were first published by the American College of Surgeons in 1991. The revised statement was developed by the Advisory Council for Cardiothoracic Surgery and approved by the College's Board of Regents in October 1996.

Preamble

This report provides guidelines to be used by hospital executives and appropriate medical staff only. It places no value judgment on existing successful programs or on the treatment of individual patients.

While current standards of practice form the basis of this report, it is recognized that large programs in cardiac surgery grow from smaller ones. Hospitals and their staffs should exercise their own discretion in approving programs based on local need and the responsibility for achieving a good standard of practice.

While attention is directed primarily to open-heart surgery, the proposed standards should apply to closed-heart operations as well as to operations on the great vessels within the chest.

In borderline situations, in which the number of open-heart operations does not meet the established guidelines, the American College of Surgeons recommends the use of peer review.

Professional team

Specification of the qualifications for cardiac surgeons in an established practice is beyond the scope of these guidelines. Surgeons practicing cardiac surgery should be certified or awaiting certification by the American Board of Thoracic Surgery or its Canadian equivalent within five years after completion of an approved residency program in cardiac surgery. It is recommended that hospital committees for staff accreditation exercise their judgments for privileges based on the nature of the cardiothoracic residency or postresidency experiences of the applicant.

A team approach with a minimum of two qualified cardiac surgeons is recommended to provide adequate and continuous perioperative care as well as assistance in the OR. It is recognized that, depending on the particular setting and situation, the assistant on a particular case may vary in experience and qualification.

Hospital operative volume–Adult cardiac surgery

The 1975 report of the Inter-Society Commission on Heart Disease Resources recommended that cardiac surgical programs in a *hospital* should perform at least 200 procedures annually. This recommendation was based on the premise of a hospital dedicating 1 operating room to cardiac surgery and functioning at 80 percent capacity (4 cases per week x 52 weeks = 200 per year). While there are no presently available data linking an *individual surgeon's* patient volume and hospital mortality rate, there are data to suggest that an annual volume of at least 100 to 125 open heart procedures (including coronary artery bypass procedures, valve replacements, and other operations requiring the use of cardiopulmonary bypass) per *hospital* is necessary from a quality standpoint and that there is a greater variation in adjusted mortality rates for teams

doing lower volumes of procedures as compared with those doing a high volume. While 100 to 125 cases per year per *hospital* appears sufficient from a quality standpoint, it is likely that considerably more, and at least 200 procedures per year as previously recommended, are necessary in order for a program to function efficiently.

Congenital heart surgery

Surgery for congenital heart disease, especially in infants, requires a setting that readily meets the complex and special needs of this group of patients. These requirements include a cardiac surgeon experienced in the operative and perioperative management of such patients. There should be a pediatric cardiologist, an anesthesia team, perfusionists, intensive care nurses, and appropriate intensive care facilities for the treatment of infants and children. At a hospital where congenital heart operations are performed, a total of 100 congenital heart operations (both open and closed, not including neonatal ductus ligations) should be done. The occasional management of an infant or child with congenital heart disease by an otherwise busy and well-functioning adult cardiac surgical team is strongly discouraged.

Hospital facilities and personnel

It is urged that hospital committees for staff accreditation use peer review to determine that adequate standards of practice are maintained in terms of case frequency and results. A registry for the recording of cardiac surgical results is mandatory.

The complex operating room environment required by cardiac surgery in terms of equipment and instruments requires constant improvement in technique and proper indoctrination of personnel. Such educational programs should be under the direction of a clearly designated individual with particular interest and skill in cardiac surgery. Operating room nurses and technicians specializing in cardiac surgery are important. It should be mandatory that operating room nurses and technicians be assigned to cardiac surgery sufficiently often to develop and maintain the skills required for proficient performance in this area.

Anesthesia for cardiac surgical patients encompasses a variety of special problems. To ensure technical competence, frequent changing of the anesthesiologists assigned to cardiac surgery should be avoided.

The operation of a heart-lung machine should be performed by a specially trained nurse or technician under the supervision of the operating surgeon. A perfusionist certified by the American Board of Cardiovascular Perfusion is recommended. Perfusionists who are not certified should have at least two years of experience under supervision in an active clinical program in open-heart surgery and have a thorough background in operating room sterile techniques, perfusion physiology, the use of monitoring equipment, and a general understanding of commonly performed cardiac surgical procedures. The primary responsibility for determining the capability of the perfusionist remains with the cardiac surgeon.

Cardiac surgeons must be primarily responsible for the postoperative care of their patients, including that provided in the intensive care unit. Portions of that care may be shared with others, such as nurses and other physicians. However, only the cardiac surgeon is fully cognizant of all aspects of a given patient's condition and retains the responsibility for the continuity of care, which includes the preoperative status, the operative management, and the postoperative care.

Intensive care nursing of cardiac surgical patients is recognized as a true specialty involving skills in dealing with cardiac and respiratory emergencies. Assignment to cardiac surgical patients should be sufficiently often to maintain competence in this area of nursing. The surgeon should participate in the supervision of cardiac intensive care unit nurses.

The operating room, intensive care unit, and other facilities must conform to standards mandated by the Joint Commission on Accreditation of Health Care Organizations.

The nature of cardiac surgery makes it mandatory that diagnostic facilities be available to the surgical team. A proper cardiac catheterization laboratory must be available for hemodynamic and cine' angiographic studies. This laboratory should be under the direction of a qualified specialist and be accessible for preoperative elective studies, postoperative elective studies, and emergency procedures on a 24-hour basis.

Standard laboratory studies should be available on a 24-hour basis, including blood-gas analysis.

A blood bank facility with full resources under the direction of qualified specialists in this field is mandatory.

An intensive care facility must be available for all patients following cardiac surgery, and in some instances, for patients who are severely ill, preoperatively. This should be a limited-access area that is off limits to nonparticipating personnel and should have facilities for the adequate isolation of septic patients.

Patient follow-up

Proper patient follow-up is an integral part of surgical treatment. An effective follow-up system for patients having open-heart surgery is the responsibility of the surgical team. The team should be able to demonstrate that it has an adequate follow-up system and that patients are seen as often as necessary during the immediate postdischarge period and, subsequently, are followed up at appropriate intervals.

Subject: information requested

Could you please indicate if there have been any updated guidelines for the minimum number of Open Heart Surgeries that "should" be done at any one institution to insure quality. Currently I have ACS guidelines from 1996 which indicate a range of 100-125 and 2004 AHA guidelines indicating the need for close monitoring of institutions performing less than 100. Is there any number currently endorsed by STS as a minimum number for an organization or individual surgeon? Your assistance is greatly appreciated in this matter.

ORIGINAL ARTICLE

Volume-Outcome Relationship for Coronary Artery Bypass Grafting in an Era of Decreasing Volume

Rocco Ricciardi, MD, MPH; Beth A. Virnig, PhD, MPH; James W. Ogilvie Jr, MD; Peter S. Dahlberg, MD; Harry P. Selker, MD, MSPH; Nancy N. Baxter, MD, PhD

Hypothesis: We hypothesized that the recent reduction in procedure volume for coronary artery bypass grafting (CABG) has led to an increase in the in-hospital mortality rate.

Design: Hospital discharge data from the Nationwide Inpatient Sample from January 1, 1988, through December 31, 2003.

Setting: A 20% random sample of patients admitted to US hospitals.

Patients: All patients who underwent CABG or percutaneous transluminal coronary interventions. Facilities performing CABG were assigned to standard volume cutoffs.

Main Outcome Measures: Rates of cardiac procedures and the proportion of hospitals meeting standard volume cutoffs, as well as the CABG mortality rate.

Results: During our 16-year study period, the rate of CABG increased from 7.2 cases per 1000 discharges in 1988 to 12.2 cases in 1997 but then decreased to 9.1 cases in 2003, while the rate of percutaneous interventions tripled. For CABG, the proportion of high-volume hospitals declined from 32.5% in 1997 to 15.5% in 2003. Despite shifts between high- and low-volume hospitals, the CABG mortality rate steadily declined from 5.4% in 1988 to 3.3% in 2003. Hospitals performing the lowest volume of CABG experienced the largest decrease in the in-hospital mortality rate.

Conclusions: Since 1997, CABG volume has declined in the setting of a decrease in in-hospital mortality. A lower mortality rate in the setting of reduced CABG volume is a counterintuitive finding, suggesting that procedure volume is an insufficient predictor of outcome on which to base regionalization strategies.

THE RELATIONSHIP BETWEEN increased hospital coronary artery bypass grafting (CABG) volume and lower mortality has been consistently observed in the clinical literature.[1-15] The robustness of this association has led some investigators to suggest that postsurgical morbidity and mortality could be reduced substantially if hospitals with little working experience in cardiac techniques stopped performing procedures such as CABG.[16-18] Other researchers estimate that the mortality rate for CABG could be reduced by 1486 deaths per year if all patients undergoing CABG were referred to hospitals that perform more than 500 CABG operations per year.[19,20] As a result, several organizations and the lay press encouraged health care purchasers to consider CABG volume when selecting providers.[21] The Leapfrog Group,[22] a health care purchasing group of more than 170 companies and organizations, established the standard of 500 CABG operations per year as a quality criterion for selecting providers.

CME available online at www.jamaarchivescme.com and questions on page 330

See Invited Critique at end of article

During the past 2 decades, the introduction and refinement of percutaneous coronary revascularization techniques have considerably affected the care of patients with coronary artery disease. The resulting drop in the number of CABG operations provides an opportunity to evaluate the effect of decreasing procedure volume on patient outcomes. These changes have led us to question what happens to the volume-outcome relationship when volume decreases significantly. Our study had the following initial aims: (1) to de-

0343
09/15/08

fine national trends in the volume of coronary revascularization techniques performed surgically (CABG) or by percutaneous transluminal coronary intervention (PTCI) and (2) to define trends in valve replacement and repair (VRR) to correct for potential database sampling bias. Next, we characterize trends in hospital volume for CABG (based on established criteria for volume[13]) to characterize the proportion of patients treated at low-, mid-, and high-volume hospitals. Therefore, 2 additional aims were the following: (3) to record mortality by year and by CABG volume to evaluate the effect of declining CABG volume on the well-defined volume-outcome relationship and (4) to quantify the difference in mortality between high- and low-volume hospitals.

METHODS

DATA SOURCES

We obtained hospital discharge data from the Nationwide Inpatient Sample (NIS) for 16 years (January 1, 1988, through December 31, 2003) via the Healthcare Cost and Utilization Project of the Agency for Healthcare Research and Quality. The NIS, the largest source of all-payer hospital discharge information in the United States, is a unique and powerful tool that includes data from about 7 million hospital stays per year in 1000 hospitals located in 35 states, approximating a 20% stratified sample of US community hospitals. Other researchers have used NIS data to review trends in surgical care and outcomes,[23] volume-outcome relationships,[13] and disparities in care.[24] A data use agreement is held by the Agency for Healthcare Research and Quality; in addition, our study protocol was considered exempt by the University of Minnesota Institutional Review Board.

PATIENTS

We used diagnostic codes from the *International Classification of Diseases, Ninth Revision* (*ICD-9*) to identify all patients who underwent CABG (codes 36.10-36.19),[13] VRR (codes 35.11, 35.21, 35.22, 35.12, 35.23, and 35.24),[15] or PTCI (codes 36.01, 36.02, 36.04, 36.05, 36.06, 36.07, and 36.09) from 1988 through 2003.

HOSPITAL VOLUME

The NIS contains hospital identifiers that permit calculation of hospital-level volume. Volumes of CABG were calculated separately in each year for each facility reporting CABG. Based on previously published methods,[13] we included all hospitals performing at least 12 CABG operations per year. Prior work by Rathore et al[13] identified significant volume-outcome effects using the following categories of annual volume: high (≥500 CABG operations), mid (250-499 operations), and low (12-249 operations); the high-volume cut point (500 operations) was selected as a minimum threshold for quality standards by the Leapfrog Group[22] during the period of our analysis. Therefore, we adopted these volume cutoffs to divide hospitals into 3 groups.

IN-HOSPITAL MORTALITY

The NIS contains information on vital status at the time of discharge. We determined the in-hospital mortality rate for all patients undergoing CABG during our study period. We also calculated the mean mortality rate by hospital volume group (high, mid, and low) and for each quarter of our study period (1988-1991, 1992-1995, 1996-1999, and 2000-2003). The NIS does not include 30-day mortality rates, so the in-hospital mortality rate was the single outcome that we calculated.

COMORBIDITY

To control for changes in patient comorbidity over time, we adjusted for comorbidity using the modification of the Charlson Comorbidity Index by Deyo et al.[25] Briefly, we ascertained the presence of 17 comorbid conditions and then weighted them according to the original study by Pompei et al.[26] An elevated Charlson Comorbidity Index has been shown to correlate with increased 1-year mortality.[26] In addition, we calculated the proportion of patients having a diagnosis of diabetes mellitus to adjust for risk during our 16-year study period. In a study[27] of administrative database coding accuracy, upcoding of diabetes mellitus was not noted over time.

STATISTICAL ANALYSIS

To compare categorical variables (patient characteristics, proportion of hospitals, and mortality) between high-, mid-, and low-volume hospitals, we used the χ^2 test. We used the t test to compare continuous variables.

We used the joinpoint regression program[28] from the Surveillance Epidemiology and End Results program of the National Cancer Institute to evaluate whether volume and mortality were variable over time. We estimated statistical significance (P value) using Monte Carlo methods and maintained the overall asymptotic significance level using Bonferroni correction.[29]

We used logistic regression analysis to determine the effect of study period (1988-1991, 1992-1995, 1996-1999, and 2000-2003) on the probability of mortality while controlling for comorbidity, payer status, patient sex, and patient age. Study period and payer status (Medicare, Medicaid, private, or other) were modeled as categorical variables, with comorbidity and patient age as continuous variables. To determine if the relationship between volume and mortality was consistent throughout our study period, we tested for an interaction between hospital volume (using the published cutoffs) and year of surgery on mortality. To identify potential changes in the relationship between hospital volume and mortality over time, we calculated odds ratios for mortality after adjusting for identified covariates. We then compared the odds ratios for mortality between high-volume and low-volume hospitals for 1988-1991 (quarter 1) and then plotted the results.

For statistical analyses, we used commercially available software (SAS version 9.13; SAS Institute, Cary, NC). All statistical tests were 2-sided, and $P \leq .05$ was considered statistically significant.

RESULTS

PATIENT CHARACTERISTICS

For our 16-year study period, we found NIS discharge abstracts for 108 087 386 patients: CABG was performed in 1 082 218 patients (1.0%), VRR in 186 483 patients (0.2%), and PTCI in 1 589 942 patients (1.5%) (**Table 1**). During our study period, 2 858 643 (CABG, VRR, or PTCI) procedures were performed. The mean age of all patients was 64.6 years; patients who underwent VRR and CABG were slightly older. About half of all patients were enrolled in Medicare. The mean Charlson Comorbidity Index score was 1.02, and the highest

Abbreviations: CABG, coronary artery bypass grafting; PTCI, percutaneous transluminal coronary intervention; VRR, valve replacement or repair.
[a] $P<.001$ for all comparisons across procedures.

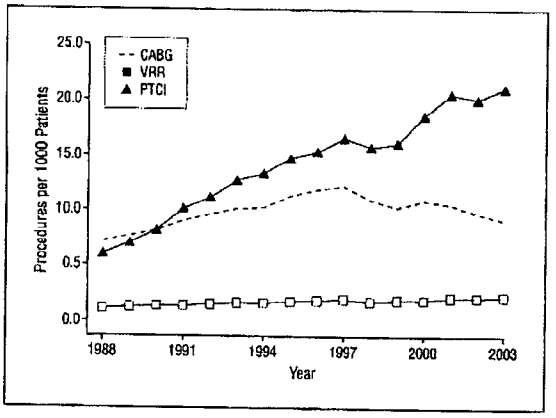

Figure 1. Coronary artery bypass grafting (CABG), valve replacement or repair (VRR), and percutaneous transluminal coronary intervention (PTCI) per 1000 patients per year.

score was for patients who underwent CABG. Diabetes mellitus was present in 24.1% of all patients undergoing CABG; its prevalence increased from 14.0% in 1988 to 31.5% in 2003.

PROCEDURE TRENDS

The number of CABG operations increased from 37 838 in 1988 to 87 160 in 1997 but decreased to 72 939 in 2003. The rate of CABG increased from 7.2 procedures per 1000 hospitalized patients in 1988 to 12.2 procedures per 1000 patients in 1997 and then declined to 9.1 procedures per 1000 patients in 2003 ($P<.001$) (**Figure 1**). Our joinpoint trend analysis revealed an increase in the rate of CABG over time until 1996 (slope, 0.60; $P<.001$). After that, our analysis revealed a reduction in the rate of CABG (slope, −0.36; $P<.001$). In contrast, the number of VRR procedures increased from 5908 in 1988 to 17 408 in 2003. The rate of VRR gradually increased from 1.1 procedures per 1000 patients in 1988 to 2.2 procedures per 1000 patients in 2003: this increase was consistent over time (our joinpoint trend analysis revealed a slow increase, without a major change in the trend [slope, 0.07; $P<.001$]).

The number of PTCI procedures increased considerably during our study period, from 31 713 in 1988 to 168 831 in 2003. The rate of PTCI increased from 6.0 procedures per 1000 patients in 1988 to 21.2 procedures per 1000 patients in 2003 (Figure 1). Our joinpoint trend analysis revealed a rapid increase in the rate of PTCI until 1993 (slope, 1.36; $P<.001$), with a more gradual increase in the ensuing years (slope, 0.84; $P<.001$). As a result of the combined decrease in CABG and increase in PTCI, the overall ratio of CABG to PTCI procedures decreased from 1.2:1 in 1988 to 0.4:1 in 2003.

HOSPITAL CABG VOLUME

The number of hospitals routinely performing CABG ranged from 119 to 233 during our study period. Overall, 52.0% of patients received care at high-volume (≥500 CABG operations per year) hospitals. Patients treated at high-volume hospitals were slightly older (mean age, 65.9 years) but were less likely to be male (70.3%) compared with patients treated at other hospitals (**Table 2**). High-volume hospitals treated a larger proportion of Medicare patients, but low-volume hospitals treated more patients with Medicaid insurance. In addition, high-volume hospitals treated a higher proportion of patients with diabetes mellitus, as well as a higher proportion of patients with 3 or more comorbidities and with higher mean Charlson Comorbidity Index scores.

The proportion of high-volume hospitals increased from 17.7% in 1988 to a peak of 32.5% in 1997 (the year of the peak volume of CABG) but then decreased to 15.5% in 2003. Conversely, the proportion of low-volume (12-249 CABG operations per year) hospitals decreased from 49.6% in 1988 to a nadir of 35.5% in 1997 but increased to 52.4% in 2003 (**Figure 2**). The number of patients

[a]Two hundred fifty-eight patients were excluded from the hospital volume calculations. $P<.001$ for all comparisons across hospital volumes.

undergoing CABG treated at high-volume hospitals increased from 16 878 (44.6%) in 1988 to 54 983 (63.1%) in 1997 but then decreased to 29 886 (41.0%) in 2003. Conversely, the number of patients treated at low-volume hospitals decreased from 7500 (19.8%) in 1988 to 9757 (11.2%) in 1997 but then increased to 17 945 (24.6%) in 2003.

CABG IN-HOSPITAL MORTALITY

In-hospital CABG mortality decreased from 5.4% in 1988 to 3.3% in 2003 (**Figure 3**). Our joinpoint trend analysis revealed a drop in mortality for CABG throughout our study period, with a more rapid decrease before 1993 (slope, −0.26; $P<.001$) compared with 1994 onward (slope, −0.09; $P<.001$). Our logistic regression analysis revealed a statistically significant reduction in mortality from 1988 to 2003 (odds ratio, 0.41; 95% confidence interval, 0.38-0.41; $P<.001$) that was not explained by changes in patient age, patient sex, payer status, or comorbidity. The overall Charlson Comorbidity Index score increased during our study period (from 0.6 in 1988 to 1.3 in 2003, $P<.001$), and the percentage of patients with 3 or more comorbidities rose from 1.2% in 1988 to 9.4% in 2003 ($P<.01$). The percentage of patients with diabetes mellitus rose from 14.0% in 1988 to 31.5% in 2003 ($P<.001$). When we excluded comorbidity from our model, we still noted a statistically significant reduction in mortality over time (odds ratio, 0.53; 95% confidence interval, 0.50-0.57; $P<.001$).

In 1988, CABG mortality in high-volume hospitals was 4.9%; in 2003, it was 3.1%. We noted a statistically significant trend toward reduced mortality in high-volume hospitals from 1990 onward ($P<.001$). Similarly, in mid-volume hospitals, mortality decreased from 5.6% in 1988 to 3.4% in 2003. A statistically significant trend toward reduced mortality in mid-volume hospitals was observed throughout our study period ($P<.002$). In low-volume hospitals, mortality decreased from 5.9% in 1998 to 3.5% in 2003. Therefore, we also noted a statistically significant trend toward reduced mortality in low-volume hospitals throughout our study period ($P<.001$).

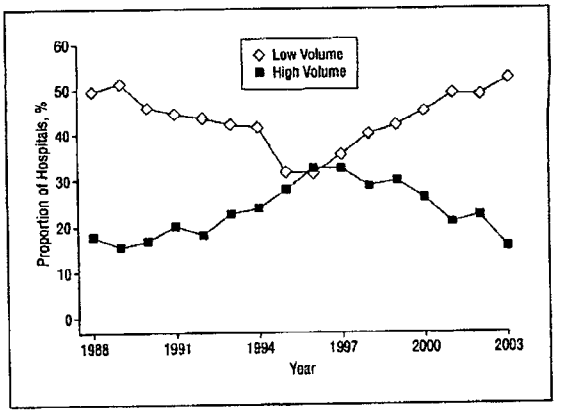

Figure 2. Proportions of coronary artery bypass grafting low-volume or high-volume hospitals by year of procedure.

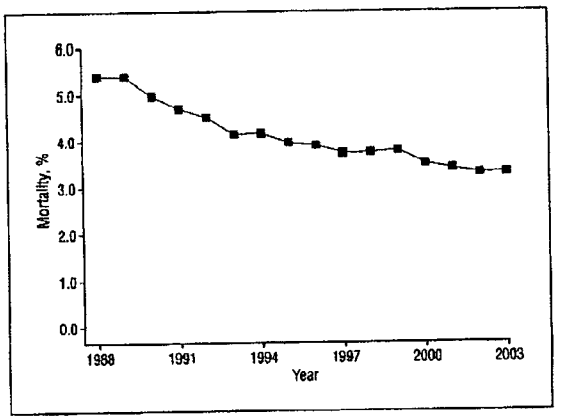

Figure 3. Overall mortality rates by year for patients undergoing coronary artery bypass grafting.

When we analyzed mortality by quarter of our study period (1988-1991, 1992-1995, 1996-1999, and 2000-2003), we observed a statistically significant difference in mortality between high-volume and low-volume hospitals, a difference that was not explained by patient characteristics or by comorbidities ($P<.001$) (**Table 3**). In addition, we identified a statistically significant interaction between quarter and hospital volume in our logistic regression model predicting mortality, indicating that the relationship between hospital volume and mortality changed over time ($P<.05$). Therefore, the difference in mortality across volume thresholds changed during the study period. The odds ratio for mortality revealed that mortality significantly decreased for all cutoffs of hospital volume over time compared with low-volume hospitals in 1988-1991. In addition, a plot of our odds ratios illustrated that the difference in mortality between high-volume and low-volume hospitals narrowed during the most recent quarter (2000-2003) (**Figure 4**).

Table 3. Patient Mortality by Hospital Volume and Quarter of the Study Period[a]

Quarter	Hospital Volume, %			P Value
	High	Mid	Low	
1988-1991	4.9	5.1	5.5	<.002
1992-1995	3.9	4.3	4.8	<.001
1996-1999	3.7	3.9	4.2	<.001
2000-2003	3.2	3.5	3.7	<.001

[a] *P* value indicates significance for comparisons across all hospital volumes.

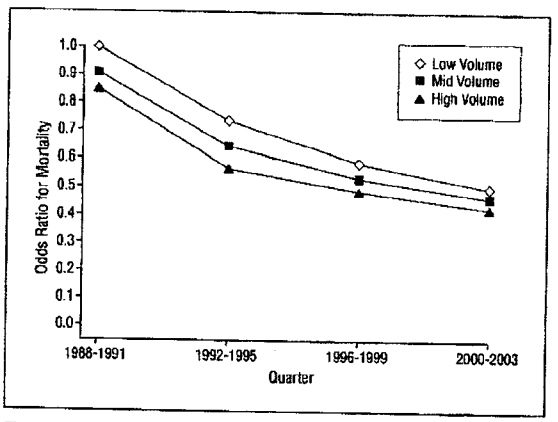

Figure 4. Odds ratios for coronary artery bypass grafting mortality compared with low-volume hospitals at the beginning of the study period. Rates are per quarter of the study period.

COMMENT

Our data confirm marked changes in CABG volume over time in the United States. Although the volumes of PTCI and VRR rose during our study period, the volume of CABG has been decreasing since its peak in 1997. Similarly, a population-based study[30] in Washington State found that CABG operations decreased 19% from 1997 to 2001. Explanations for the reduced rate of CABG surgery include improvements in minimally invasive approaches to coronary revascularization,[31] enhancements in PTCI techniques, the development of drug-impregnated stents,[32] and the advent of new anticoagulant agents.[33,34] In addition, behavioral, societal, and medical efforts at prevention may have reduced the overall proportion of patients with cardiovascular risk factors and, consequently, with coronary artery disease.[35]

The effect of decreased CABG volume has not been evaluated in the literature, to our knowledge, until our study. It stands to reason that the decreasing CABG volume has an effect on patient outcome. However, in addition to the overall reduction in CABG operations, our data demonstrate marked reductions in the proportion of institutions classified as high-volume hospitals and in the proportion of patients treated at the Leapfrog Group's high-volume hospitals. If a causal relationship exists between a high procedure volume and a good outcome, then findings of (1) an overall reduction in CABG volume and (2) a reduction in the proportion of patients treated at high-volume hospitals should affect mortality. Specifically, with a decline in CABG volume, one would predict a rise in mortality since 1997. Instead, our study reveals a significant reduction in mortality in the face of reduced aggregate procedure volume.

As overall CABG volume declined from 1997 onward, overall CABG mortality also significantly declined from 3.7% in 1997 to 3.3% in 2003. This counterintuitive finding may be explained by (1) a dissemination of improved quality care practices to the community or (2) a shift of once high-volume hospitals, with presumed lower mortality rates because of structural variables that remained constant, into the low-volume group. A definitive explanation cannot be obtained from our data. We also found significant improvement across all volume groups over time, as well as overall improvements in the mortality rate since 1997, despite the fact that fewer patients were treated at high-volume hospitals. Therefore, care of patients undergoing CABG has improved independent of volume. Previous research confirmed a dissemination of improved quality care practices at multiple institutions in the area of CABG surgery.[36] Given the reduction in CABG volume and the dramatic increase in patients treated at low-volume hospitals, regionalization strategies were not responsible for the improvements in the mortality rate that we identified.

Our data indicate that in-hospital mortality rates and, possibly, quality care practices are improving everywhere independent of CABG volume. In fact, the low-volume hospitals had the most substantial reduction in CABG mortality. In 2003, the absolute difference in mortality between high-volume and low-volume centers was small. This finding should challenge the setting of any arbitrary volume cut point: positive effects on patient outcome are multifactorial and are inadequately described by procedure volume. In addition, the in-hospital mortality rate after CABG may have diminished to such low levels that it is no longer a useful marker of quality. It may still be valuable in identifying outliers, but in terms of evaluating quality of care in further CABG outcome studies, other end points may be more valuable.

Our use of an administrative database for analysis of medical services has limitations and strengths. First, *ICD-9* procedure coding was consistently recorded throughout our 16-year study period and is known to be highly accurate. Yet, despite the noted accuracy of *ICD-9* coding, a significant limitation of our study is the lack of all potential medical items in the hospital record. In addition, we were unable to directly compare in-hospital mortality rates with 30-day mortality rates; however, these 2 rates have been shown to be highly correlated.[37] Second, we noted a secular trend toward higher comorbidity coding; however, the results of our logistic regression model were similar with and without adjustment for comorbidities. Our data represent a large sample of CABG operations in the United States, not restricted to subjects enrolled in Medicare. Therefore, we believe that our

0347
09/15/08

results provide generalizable population-based estimates of the CABG volume-outcome relationship.

In conclusion, our study revealed a significant decrease in CABG volume since 1997 in the setting of a significant rise in PTCI. Also since 1997, the number of patients undergoing CABG treated at high-volume hospitals and the proportion of high-volume hospitals have decreased significantly. Despite this reduction in patients undergoing CABG at high-volume hospitals, the overall pooled CABG mortality decreased significantly during the study period. Reduced CABG volume in the setting of decreased mortality is a counterintuitive finding given the robust converse relationship between volume and outcome. Therefore, our findings have important implications for our understanding of the volume-outcome relationship and should dampen enthusiasm for regionalization of CABG care based solely on volume.

INVITED CRITIQUE

It has been assumed by many, based on previous studies,[1,2] that there is a linkage between hospital cardiac surgical case volumes and outcomes, whereby improved outcomes are associated with high-volume centers. Regionalization strategies and recommendations, adopted by state certificate of need regulations and health care industry consortia (eg, the Leapfrog Group), are largely predicated on these assumptions in that they espouse concentrating bypass surgery procedural volumes in the interest of improving quality and outcomes. Findings from this article suggest that such traditional volume-outcome tenets may be overly simplistic and inaccurate in assessing current CABG practices. In an analysis of the Society of Thoracic Surgeons' National Cardiac Surgery Database, DiSesa et al[3] recently reported that, although certificate of need regulations have been successful in increasing hospital CABG volumes, their effect on procedural mortality or morbidity seems to be negligible. There is growing experiential evidence that hospital-based quality control, monitoring, and best-practice programs may have a more significant effect on outcomes.

It is intriguing that Dr Ricciardi and colleagues found that lower-volume CABG centers have recently experienced reduced mortality rates, fueling the notion that lower-volume community centers with rigorous quality control mechanisms may be better able to provide superior perioperative care than traditional high-volume academic centers. Although difficult to evaluate objectively, high-volume academic centers should not underestimate the negative effect of recently enforced restricted residency hours on the quality of perioperative care readily available to high-acuity postoperative patients.

Coronary artery bypass grafting has been selected as an index operation for this and other outcome analyses presumably because of its high volume, high acuity, and expense. One must be cautious, however, in applying the conclusions of such analyses based on generally routine operations to other less frequently performed, more technically complex, and specialized cardiac operations (eg, complex mitral valve repair, aortic root or arch reconstructions, and Norwood procedures). It would seem that operative outcomes among such operations might better adhere to traditional volume-outcome assumptions.

Health Care Outcomes

The CABG Surgery Volume–Outcome Relationship: Temporal Trends and Selection Effects in California, 1998–2004

James P. Marcin, Zhongmin Li, Richard L. Kravitz, Jian J. Dai, David M. Rocke, and Patrick S. Romano

Objective. To investigate the temporal trends in the volume–outcome relationship in coronary artery bypass graft (CABG) surgery in California from 1998 to 2004, and to assess the selection effects on this relationship by using data from periods of voluntary and mandatory hospital reporting.

Data Sources. We used patient-level clinical data collected for the California CABG Mortality Reporting Program (CCMRP, a voluntary reporting program with between 68 and 81 hospitals) from 1998 to 2002 and the California CABG Outcomes Reporting Program (CCORP, a mandatory reporting program with 121 and 120 hospitals) from 2003 to 2004.

Study Design. The patient was the primary unit of analysis, and in-hospital mortality was the primary outcome. We used hierarchical logistic regression models (generalized linear mixed models) to assess the association of hospital annual volume with hospital mortality while controlling for detailed patient-level covariates in each of the 7 years.

Data Collection Methods. All data were systematically collected, reviewed for accuracy, and validated by the State of California's Office of Statewide Health Planning and Development (OSHPD).

Principal Findings. We found that during the period of voluntary hospital reporting (1998–2002), with the exception of 1998, higher volume hospitals had significantly lower risk-adjusted in-hospital mortality rates, on average, than lower volume hospitals (1998 odds ratio [OR] per 100 operations performed = 0.962, 95 percent confidence interval [CI]: 0.912–1.015; 1999 OR = 0.955, 95 percent CI: 0.920–0.991; 2000 OR = 0.942, 95 percent CI: 0.897–0.989; 2001 OR = 0.935, 95 percent CI: 0.887–0.986; 2002 OR = 0.946, 95 percent CI: 0.899–0.997). We also found that in the period of mandatory reporting (2003 and 2004) there was no volume–outcome relationship (2003 OR = 0.997, 95 percent CI: 0.939–1.058; 2004 OR = 0.984, 95 percent CI: 0.915–1.058) and that this lack of association was not due to a reporting bias from the addition of data from hospitals that did not originally contribute during the voluntary program.

0350
09/15/08

Conclusions. In California, where no state regulations support regionalization of CABG surgeries, a weak volume–outcome relationship was present from 1998 to 2002, but was absent in 2003 and 2004. The disappearance of the volume–outcome association was temporally related to the implementation of a statewide mandatory CABG surgery reporting program.

Key Words. Volume–outcome relationship, coronary artery bypass graft surgery, regionalization of services, risk adjustment, multilevel modeling

---

The association between the quantity of care that a physician or hospital provides and the quality of care that patients receive has been rigorously studied by clinicians and health services researchers (Luft, Bunker, and Enthoven 1979; Birkmeyer et al. 2003; Gandjour, Bannenberg, and Lauterbach 2003). This "volume–outcome" relationship has been documented for a wide variety of medical conditions and surgical procedures at the physician, clinical team, and hospital level of care (Halm, Lee, and Chassin 2002; Elixhauser, Steiner, and Fraser 2003). In a report reviewing the volume–outcome relationship published by the Institute of Medicine, the authors noted that 77 percent of the published volume–outcome studies had demonstrated a significant relationship between higher physician and hospital volumes and better health outcomes (Hewitt et al. 2001).

The volume–outcome relationship has been most intensely studied for patients receiving coronary artery bypass grafting (CABG) surgery, perhaps because regionalization is a particularly promising policy strategy to improve care for high-risk elective surgery. Although many studies have found that hospitals performing relatively more CABG surgeries have better outcomes (Luft, Bunker, and Enthoven 1979; Birkmeyer et al. 2002, 2003; Hannan et al. 2003; Peterson et al. 2004), the importance of this relationship for health policy

remains controversial. First, several recent studies using robust statistical methods and careful risk adjustment have found either minor or insignificant hospital CABG volume–outcome relationships, or no relationship at all (Christiansen and Morris 1997; Shahian et al. 2001; Kalant and Shrier 2004; Peterson et al. 2004). Second, studies of regionalization policies have been inconclusive regarding their impact on improving care (Vaughan-Sarrazin et al. 2002; Nobilio and Ugolini 2003). Third, there is some evidence that the observed volume–outcome association may reflect selective referral of patients to high-quality surgeons and hospitals, rather than greater experience leading to improved skills (Luft et al. 1990; Escarce et al. 1999).

In addition, the effect of public reporting of CABG surgery performance on the volume–outcome relationship is unknown. In several studies, the publication of CABG surgery quality reports has been associated with reduced CABG mortality (Hannan et al. 1995; Rosenthal, Quinn, and Harper 1997; Romano and Zhou 2004) and enhanced quality improvement efforts, particularly for low-quality and low-volume outliers (Bentley and Nash 1998; Rainwater, Romano, and Antonius 1998; Chassin 2002). Therefore, public performance data may help stimulate standardization of procedures, improved training, acquisition of better equipment, and diffusion of innovation, thereby improving outcomes among low-quality and low-volume outliers and attenuating the volume–outcome relationship. Further, as some of the studies that have reported a significant volume–outcome relationship used data from voluntary reporting programs, selection bias could have contributed to misestimation of the volume effect (Clark 1996; Christian et al. 2003; Peterson et al. 2004). For example, the volume–outcome relationship could be overestimated if nonparticipating low-volume hospitals had better than average outcomes or if nonparticipating high-volume hospitals had worse than average outcomes.

The goal of this study was to investigate the volume–outcome relationship for CABG surgery in California from 1998 to 2004, a period during which public reporting of CABG outcomes transitioned from a voluntary basis to a state-mandated program. We analyze data from the California CABG Mortality Reporting Program (CCMRP), a voluntary reporting program with between 68 and 81 participating nonfederal hospitals from 1998 to 2002, and from the California CABG Outcomes Reporting Program (CCORP), a mandatory reporting program with 121 and 120 nonfederal hospitals from 2003 to 2004, respectively. Our objectives were (1) to use hierarchical logistic regression to determine whether hospitals performing more CABG surgeries have lower risk-adjusted mortality than hospitals performing fewer cases, and (2) to

0352
09/15/08

assess potential explanations for any change in the magnitude of the volume–outcome association between the voluntary reporting period (1998–2002) and the mandatory reporting period (2003 and 2004).

METHODS

The CCMRP was established in 1995 as a joint activity between the California Office of Statewide Health Planning and Development (OSHPD) and the Pacific Business Group on Health (PBGH). This voluntary program collected data from 1997 through 2002. The first CCMRP report was publicly released in July 2001 and presented data from 1997 to 1998 (Damberg, Chung, and Steimle 2001). The second report was released in August 2003 and presented data from 1999 (Damberg et al. 2003). The third report was released in February 2005 and presented data from 2000 to 2002 (Parker et al. 2005a). Beginning in 2003, data reporting became mandatory for all licensed nonfederal hospitals performing CABG surgery in California. The mandatory reporting program, referred to as the CCORP, published its first report in February 2006, based on data collected during 2003 (Parker et al. 2005b). The second CCORP report, to be published in 2007, will include physician-level data from 2003 to 2004.

The data used in this article include 5 years of data from the voluntary CCMRP (1998–2002) plus the first 2 years of data from the mandatory CCORP program (2003 and 2004). The data from 1997, the first year of the CCMRP, only included 34 hospitals and were therefore not included in these analyses. Further details on the CCMRP and CCORP reports including specifics on data collection, validation procedures, and statistical methods have been published (Parker et al. 2005a, b) and are available online (http://www.oshpd.ca.gov/hqad/outcomes/clinical.htm).

Data Elements

CCMRP and CCORP collect patient-level data elements defined by the Society of Thoracic Surgeons (STS) in its National Adult Cardiac Surgery database (Welke et al. 2004) as well as other state programs (Table 1) (Shroyer et al. 2003; Massachusetts Data Analysis Center [MASS-DAC] 2004; New York State Department of Health 2004; New Jersey Department of Health and Senior Services 2005; Pennsylvania Health Care Cost Containment Council 2005). To ensure the quality and comparability of data submitted, OSHPD

provided hospitals with training sessions and written guidance in the form of a data collection handbook.

Data Quality Review and Verification

The data submitted by each hospital for both the CCMRP and CCORP were systematically reviewed for completeness, data errors, and data discrepancies. The first step was to compare each hospital's specific rates for each data element to the state average. Invalid, missing, and abnormally high- or low-risk mean values and prevalences were identified. Reports were then generated for each hospital with discrepancies and each of these hospitals was asked to check for possible coding errors. The second step was to link the CCMRP and CCORP data with the State of California's Patient Discharge Data (PDD) to conduct further validation. This matched data set was used to generate additional reports to alert hospitals with apparent discrepancies in the number of isolated CABG surgeries performed or the number of in-hospital deaths. The relevant hospitals were contacted and asked to check the cases by reviewing medical records.

The PDD-CCMRP and PDD-CCORP linkages were also used to verify selected risk factors. Although the selected risk factors reviewed varied between years, they generally included the prevalence of cardiogenic shock, the use of percutaneous transluminal coronary angioplasty, the need for dialysis, myocardial infraction, and whether the surgery was considered a "salvage" case. The specific findings of these discrepancy reports and the hospital reconciliations are summarized in the CCMRP and CCORP reports (Parker et al. 2005a, b). Finally, independent medical record audits were undertaken for the CCORP data, but not the CCMRP data. Details of the audit, the audit results, and subsequent interventions are available in the CCORP report (Parker et al. 2005b).

Risk Adjustment Model

Multivariable logistic regression models were used to determine the relationship between each of the demographic and preoperative risk factors and the likelihood of in-hospital mortality. Details regarding risk model development are available elsewhere (Parker et al. 2005a, b). Briefly, the risk models were developed for the CCMRP and CCORP data separately. Table 1 lists the factors used in the risk adjustment compared with the factors included in the STS model and models used by the states of New York, New Jersey, Pennsylvania, and Massachusetts. The coefficients were developed on the patients

0356
09/15/08

included in the data sets without any missing variables (more than 89 percent of the cases in both data sets) to ensure that the effects of risk factors were estimated based on the most complete data available. Then, for all patient fields that were incomplete, parameters were imputed using the lowest risk category, so that there were no missing data in any of the seven final data sets (one for each year).

Volume–Outcome Models

To assess the association between annual hospital volume of isolated CABGs and risk-adjusted mortality, annual hospital volume (the only fixed effects hospital-level variable) was specified in three ways. First, we entered annual volume as a continuous variable for each year-specific model. Second, we entered annual volume as a quadratic (linear plus squared term) for each year-specific model to evaluate a possible curvilinear relation between mortality and volume. Third, we dichotomized volume using two volume thresholds that we selected before any analyses. By this method, hospitals were dichotomized as performing fewer than 250 or at least 250 CABG cases/year, as well as hospitals performing fewer than 450 or at least 450 cases/year, consistent with previously used volume thresholds (Birkmeyer et al. 2003; Parker et al. 2005a, b). Of note, a hospital could therefore be categorized as low volume in one year and high volume in another year if the number of CABG procedures crossed the specified volume threshold. Finally, to assess whether other transformations should be considered, for each year as well as for all years combined, we generated scatterplots of observed mortality versus volume and of risk-adjusted mortality versus volume, and produced locally weighted least squares (LOWESS) curves for visual inspection (Cleveland 1979; Royston 1991).

For data collected during the mandatory reporting program in 2003 and 2004, we conducted separate analyses on the 86 and 85 hospitals, respectively, that had previously reported data during any of the 5 years of the voluntary reporting period (CCMRP). This was done to assess potential explanations for any change in the magnitude of the volume–outcome association between the voluntary reporting period (1998–2002) and the mandatory reporting period (2003 and 2004).

Statistical Methods

The CABG volume–outcome relationship was analyzed with a hierarchical logistic regression model (PROC GLIMMIX, SAS, version 9.1) with hospital-

0357
09/15/08

specific random intercepts. These models are increasingly used in health services research to analyze multilevel data, such as patient data that are aggregated by hospital (Christiansen and Morris 1997; Shahian et al. 2001), and provide several theoretical and statistical advantages. These models are more appropriate for using patient data to make inferences at the hospital level by adjusting for the "clustering" of patients with similar characteristics (Christiansen and Morris 1997; Shahian et al. 2001). To aid in the visual inspection of the volume–mortality scatterplots, LOWESS curves were fitted to the data using *Stata*, version 9.2 (Cleveland 1979; Royston 1991).

RESULTS

Overall hospital volume and mortality data are presented in Table 2. During the voluntary reporting program years of 1998, 1999, 2000, 2001, and 2002, the number of hospitals contributing data were 68, 81, 76, 71, and 70, respectively. During the mandatory program years of 2003 and 2004, the number of hospitals performing CABG surgeries was 121 and 120, respectively. Of these hospitals, 86 and 85, respectively, had previously participated in at least one of the years during the prior voluntary program. The median annual hospital CABG volume generally decreased over the years studied; from its peak in 2000, the median annual hospital CABG volume fell to 120 for all

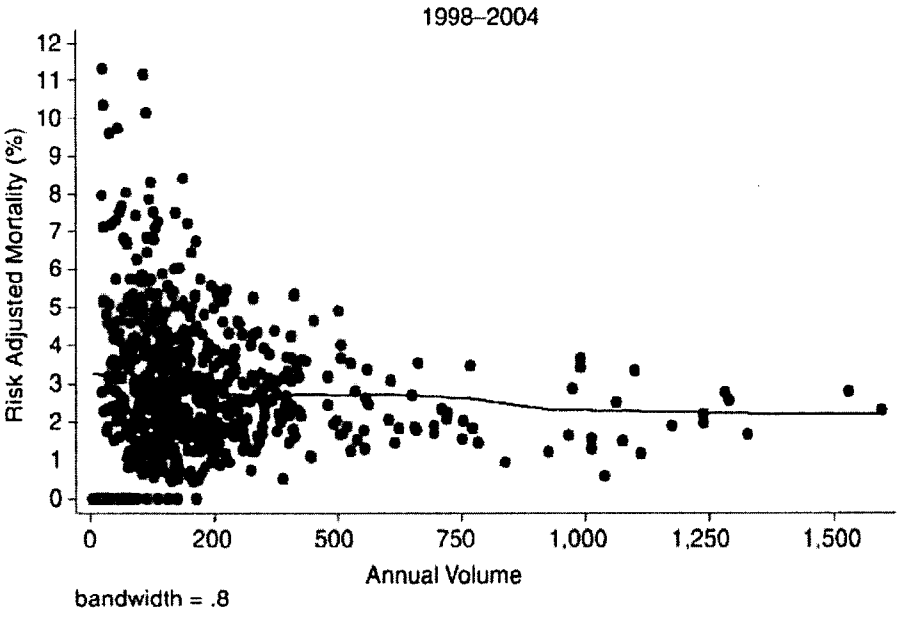
hospital volume and lower mortality in 1999, 2000, 2001, and 2002. While this association was not statistically significant in 1998, the OR associated with hospital volume was similar when compared to the four following years; however, there were fewer patients in the 1998 cohort. To give an example of the magnitude of this association, in the year 2000, the OR associated with each additional 100 CABG procedures performed was 0.942. Therefore, a hospital with the median in-hospital mortality rate of 2.88 percent would be expected to have its mortality rate drop by 0.17 percentage point to 2.71 percent if it performed 100 additional procedures. During 2003 and 2004, there was no significant volume–outcome association among either the hospitals that had previously reported during the voluntary program or the entire set of hospitals reporting in the mandatory program.

When hospital volume was entered as a quadratic term (linear plus squared), the squared term was not significant in eight of the nine models. In the year-specific model for 2000, the squared term was significant with a coefficient = 0.000002, 95 percent confidence interval [CI]: 0.0000007–0.0000033, $p = .004$.



When annual hospital volume was dichotomized as fewer than 250 cases versus 250 or more, a significant association was found between volume and outcome during the years, 2000–2002. This association disappeared during the mandatory reporting years, 2003 and 2004, with ORs of 1.007 (95 percent CI: 0.737–1.376) and 0.999 (95 percent CI: 0.731–1.366) for the hospitals that had participated in the voluntary program, and 1.089 (95 percent CI: 0.827–1.435) and 1.177 (95 percent CI: 0.856–1.618) for all hospitals performing CABG surgeries, respectively. This suggests that this loss of association did not result from including hospitals that had not participated in the voluntary program.

When annual hospital volume was dichotomized as fewer than 450 cases versus 450 or more, the ORs for mortality among high-volume hospitals compared with low-volume hospitals ranged from 0.587 to 0.769 from 1998 to 2002. For the years 2003 and 2004, the ORs were 1.016 and 0.951, respectively, for all hospitals and 1.052 and 0.900, respectively, for hospitals that had previously reported during the voluntary, CCMRP reporting period. Of note, only six hospitals during the mandatory program performed 450 or more cases/year.

Finally, upon visual inspection of scatterplots and LOWESS curves of observed mortality and hospital volume, and risk-adjusted mortality and hospital volume, we found no evidence of nonlinear associations or evidence to suggest that other transformations or dichotomization thresholds should be considered. Figure 1 shows the scatterplot of risk-adjusted mortality versus annual volume for all years, 1998–2004. The scatterplots and LOWESS curves

DISCUSSION

In California, we found that the hospital volume–outcome relationship for CABG surgery was consistent but small during the years 1998–2002, and that this relationship disappeared in 2003 and 2004. We found that the use of data collected during a voluntary statewide reporting program (1998–2002) appeared to yield unbiased estimates of the volume effect. That is, when we assessed the volume–outcome relationship for 2003 and 2004, conducting separate analyses on all hospitals as well as those hospitals that had previously participated in the voluntary reporting program, we found similar results. The disappearance of the volume–outcome relationship resulted, in part, from improved risk-adjusted outcomes among lower volume hospitals. It is unknown whether the overall improvement in mortality, especially at low-volume hospitals, during this study period was partially attributable to the state's public reporting of CABG surgery performance data. Low-volume hospitals

0361
09/15/08

may have implemented improved training programs, quality improvement activities, or other innovations to improve outcomes; these interventions may have been stimulated partially by the prospect of mandatory public reporting.

The policy implications of the volume–outcome association are important. If a clinically significant volume–outcome association exists, then legislators and policy makers should establish minimum volume guidelines and/or promote the regionalization of such services, as the New York Department of Health has done for many years. More patients would then receive care in higher volume centers, and average quality of care would improve. There are data that support this policy direction. Two large observational studies (Grumbach et al. 1995; Vaughan-Sarrazin et al. 2002) have compared outcomes of patients after CABG surgery in areas of high regionalization (e.g., Canada and New York) to areas of low regionalization (e.g., California). These reports have suggested that higher volume centers have lower mortality rates and that areas of high regionalization have better outcomes and less variability in outcomes when compared with areas of low regionalization. However, both of these studies used administrative data, which are inferior in their ability to risk adjust (Wray et al. 1997). Second, the data used in these analyses were from 1987–1989 (Grumbach et al. 1995) to 1994–1999 (Vaughan-Sarrazin et al. 2002) when overall CABG surgery mortality was higher and the volume–outcome association was more pronounced.

Our finding that the volume–outcome relationship has diminished over time is consistent with previous reports (Sowden, Deeks, and Sheldon 1995; Clark 1996; Kalant and Shrier 2004). In a recent literature review, Kalant and Shrier (2004) found that studies from the 1980s demonstrated that the risk of death after CABG surgery was 3–5 percent less at high-volume centers than at low-volume centers. Studies since 1990, on the other hand, have generally found that the risk of death after CABG surgery is between 0 and 3 percent less at high-volume centers (Kalant and Shrier 2004). These and other authors suggest that this trend is due to both general advances in medicine and maturation of the CABG procedure (Shahian and Normand 2003; Kalant and Shrier 2004). Peterson et al. (2004) analyzed data from 2000 to 2001 using the STS National Cardiac Database and found only a very small volume–outcome association, corresponding to a reduction in mortality of 0.07 percent for every additional 100 CABG surgeries performed (Peterson et al. 2004). Birkmeyer et al. 2002 also found a <2 percent difference in adjusted mortality between very low- and very high-volume hospitals performing CABG surgery in a national sample of Medicare patients. The most current data and systematic reviews of the CABG volume–outcome relationship conclude that caution

0362
09/15/08

should be exercised to avoid overinterpreting the significant findings of previous studies and that hospital volume may no longer be an adequate quality metric for CABG surgery (Sowden, Deeks, and Sheldon 1995; Sowden and Sheldon 1998; Shahian and Normand 2003; Kalant and Shrier 2004).

Using databases in which hospitals voluntarily report performance data to estimate the volume–outcome relationship could lead to selection bias. Several analyses reporting significant volume–outcome associations have used such databases (Clark 1996; Christian et al. 2003; Peterson et al. 2004). Bias could be introduced if either low- or high-volume hospitals not participating in the voluntary program had worse than average outcomes, resulting in either an under- or overestimation of the volume–outcome relationship, respectively. While other studies have shown that nonparticipating entities tend to have worse outcomes than participating entities (McCormick et al. 2002), ours is the first study that directly evaluated this potential bias for the CABG surgery volume–outcome relationship. Although we found the hospitals that did not participate in the voluntary program tended to be smaller and have higher observed mortality rates, including them in the full analyses did not significantly change the lack of volume–outcome association during the mandatory reporting program. These previously nonparticipating hospitals had similar risk-adjusted mortality rates in 2003 and 2004 as those previously participating hospitals, on average.

It is also possible that in California, the introduction of a mandatory CABG surgery outcome reporting program stimulated quality improvement efforts, particularly among low-quality outliers. While several studies have suggested that the publication of CABG surgery reports has been associated with reductions in CABG mortality (Hannan et al. 1995; Rosenthal, Quinn, and Harper 1997) and improvements in quality of care (Bentley and Nash 1998; Rainwater, Romano, and Antonius 1998; Chassin 2002), it is unknown whether the observed reduction in hospital mortality, particularly among hospitals performing fewer than 250 surgeries/year, and the recent lack of a volume–outcome association in California reflects such improvements. Clearly, other factors may have contributed to this temporal finding, including patient selection, standardization of procedures, improved training, better equipment, and diffusion of innovation. Of note is the fact that expected mortality rates remained stable among low-volume hospitals throughout the study period, arguing against the possibility of low-volume hospitals inflating clinical risk factors during the mandatory program. It is also not known whether our findings reflect trends in other states or nationally, or whether they might be limited to states with public reporting programs or those that

0363
09/15/08

collect clinical data. Another limitation of our study is that we only examined 7 years of data, and the absence of the volume–outcome association may not be sustained. In addition, relative to other states, California has low-volume CABG centers, and there may be a volume–outcome association above the volumes reflected in the California data. Finally, our risk-adjustment models, although based on detailed clinical data similar to those collected in New York and New Jersey, may have omitted unidentified confounders.

Although many studies have supported the existence of an association between CABG hospital volume and mortality, this association has decreased with time, and in our analyses of the most recent California data, the relationship has disappeared. Our findings, in combination with the findings of other researchers, challenge the proposition that regionalizing services will result in improved quality of care, and raise questions about the validity of the Leapfrog Group's Evidence-based Hospital Referral standards for CABG volume. Other interventions, such as public reporting and collaborative quality improvement, may foster resolution of outcome disparities between low- and high-volume hospitals. Future analyses are clearly warranted to investigate whether the volume outcome association still exists for other cardiovascular procedures or in other states that do not impose regionalization.

CARDIOVASCULAR

Limitations of Hospital Volume as a Measure of Quality of Care for Coronary Artery Bypass Graft Surgery

Karl F. Welke, MD, Mitchell J. Barnett, PharmD, MS, Mary S. Vaughan Sarrazin, PhD, and Gary E. Rosenthal, MD

Division of Cardiothoracic Surgery, Oregon Health and Science University, Portland, Oregon; and Center for Research in the Implementation of Innovative Strategies in Practice (CRIISP), Iowa City VA Medical Center, and Department of Internal Medicine, Division of General Internal Medicine, University of Iowa Carver College of Medicine, Iowa City, Iowa

Background. While prior research has found an inverse relationship between hospital volume and mortality after coronary artery bypass graft surgery (CABG), the use of volume as a proxy for quality and a means for selecting hospitals is controversial. The objective of this study is to quantify the relationship between hospital volume alone and CABG mortality.

Methods. A retrospective cohort of 948,093 Medicare patients undergoing CABG in 870 US hospitals from 1996 to 2001 was categorized into quintiles, based on hospital CABG volume. Hospitals were also classified by volume criterion proposed by the Leapfrog Group. Logistic regression was used to adjust hospital mortality rates (in-hospital or within 30 days after CABG) for patient characteristics; discrimination of the volume categories was assessed by the *c* statistic.

Results. The range in risk-adjusted mortality for hospitals within the quintiles was substantial: 1% to 17% at very low, 2% to 12% at low, 2% to 10% at medium, 2% to 9% at high, and 3% to 11% at very high volume hospitals. Moreover, volume alone was a poor discriminator of mortality (*c* statistic = 0.52). Similar variation in adjusted mortality was seen within the Leapfrog low-volume (1% to 17%) and high-volume groups (2% to 11%), and the Leapfrog criterion was a poor discriminator of mortality (*c* statistic = 0.51). Of the 660 low-volume Leapfrog hospitals, 253 (38%) had risk-adjusted mortality rates that were similar to or lower than the overall risk-adjusted mortality of high-volume hospitals (5.2%).

Conclusions. Volume alone, as a discriminator of mortality, is only slightly better than a coin flip (*c* statistic of 0.50).

(Ann Thorac Surg 2005;80:2114–20)

Many authors have reported an inverse relationship between hospital surgical volume and perioperative mortality after coronary artery bypass graft surgery (CABG) [1–5]. These reports have received broad attention and have led many to propose volume as a proxy for quality of care. The Leapfrog Group, a consortium of 140 private and public purchasers of health insurance providing benefits to 34 million people, is encouraging patients to undergo CABG at hospitals that perform more than 450 procedures per year [6, 7]. The lay media and consumer groups are reporting hospital volumes and suggesting hospital CABG volume as a factor in patient choice [8, 9].

Much about the volume outcomes relationship remains unexamined, however. While nearly all prior studies of CABG have found statistically significant relationships between volume and mortality, these studies have typically utilized large health care databases and had exceptional statistical power to detect small differences across different categories of volume. Moreover, few studies have clearly articulated the strength of volume as a predictor of mortality and how patients should weigh it when choosing a hospital. Since patients are being encouraged to make their choice of hospital in part based on surgical volume, such information is essential, particularly for patients who may need to travel considerable distances to higher volume hospitals and leave their local support systems.

The purpose of this study is to quantify the strength of hospital volume as a predictor of an individual patient's risk of mortality after CABG, both in absolute terms and relative to the strength of previously validated approaches of risk-adjusting CABG hospital mortality rates. Such approaches may help illuminate the potential utility of volume as a marker of hospital quality, particularly for large employers and health plan administrators who have been encouraged to use volume as a criterion in selective contracting.

Patients and Methods

The study was designed as a retrospective cohort analysis using data derived from the Medicare Provider and Analysis Review (MEDPAR) Part A public use data files, which were obtained from the Center for Medicare and

Medicaid Services. The MEDPAR Part A files include data available on the Uniform Billing-92 hospital discharge abstract for all Medicare beneficiaries discharged from acute care hospitals with the exception of patients enrolled in risk-bearing health maintenance organizations. The files are matched quarterly to the Medicare enrollment database to obtain dates of death for Medicare beneficiaries who died after hospital discharge.

The eligible sample included 1,073,956 patients 65 years of age and older who underwent CABG in 1,174 US hospitals during a 6-year period from January 1, 1996, to December 31, 2001. Patients were identified on the basis of appropriate *International Classification of Diseases, 9th Clinical Modification* (ICD-9-CM) codes for CABG (36.10–36.19). Consistent with prior studies [3, 10], patients who underwent cardiac valve replacement at the time of CABG (n = 70,242, 6.5%) were excluded from analysis, as were 318 patients (0.03%) discharged from hospitals with 5 or fewer CABG procedures in the MEDPAR data because of the possibility that such cases could be ICD-9 CM coding errors rather than actual CABG procedures. Lastly, 55,621 patients (5.1%) who underwent CABG at 225 hospitals that did not perform CABG during all 6 years of the study period were excluded to minimize the impact of random variation in mortality rates and maximize the robustness of volume outcome relationships. These exclusions left a final sample of 948,093 patients who underwent CABG in 870 US hospitals.

Hospital volume was defined as the average number of CABG procedures performed per year in Medicare beneficiaries over the 6 years of the study and was analyzed using four approaches. First, volume was evaluated as a continuous variable. Second, hospital volume was categorized into quintiles by selecting whole-number division points that most closely sorted the sample into five equal-size patient cohorts: very low (fewer than 125 yearly), low (125 to 204 yearly), medium (205 to 299 yearly), high (300 to 449 yearly), and very high (more than 449 yearly). Third, a similar approach was used to apportion the sample into deciles. Fourth, hospitals were placed into high- and low-volume categories using the current criterion of the Leapfrog Group of 450 procedures per year. Because the Leapfrog criterion considers total volume, a cutpoint of 256 was used for the current sample, given that roughly 57% of CABG procedures in the United States are performed in Medicare beneficiaries [3].

The primary study endpoint was mortality that occurred within 30 days of surgery or during the index hospitalization for CABG. Secondary endpoints included mortality that occurred within 7, 14, 30, 90, and 365 days of surgery.

Several approaches were used to define the relationships between hospital volume and mortality. First, unadjusted mortality rates across volume groups were compared using the chi-square statistic for linear trend. Second, the discrimination of volume alone as a predictor of mortality was assessed by the *c* statistic (11, 12) as determined from univariate logistic regression analyses for each of the four approaches for analyzing hospital volume described above. The *c* statistic is numerically equivalent to the area under a receiver operator characteristic curve and represents the proportion of times that a given patient who died had a higher predicted risk of death (on the basis of hospital volume in this case) than a given patient who lived. The *c* statistic ranges from 0.5 to 1.0 and has been widely reported for multivariable models predicting mortality for patients undergoing CABG. A test with perfect discrimination has a *c* statistic of 1.0. A test with no discrimination has a *c* statistic of 0.5, namely, a coin flip. To maximize potential discrimination, the quintile and decile volume categorizations were modeled using indicator variables for individual volume categories, in lieu of a single ordinal variable. The *c* statistics were also determined for the primary (30-day or in-hospital mortality) and each of the secondary endpoints (7-, 14-, 30-, 90-, and 365-day mortality) using the four approaches for modeling hospital volume.

Table 1. Baseline Characteristics of the 948,093 Study Patients Undergoing Coronary Artery Bypass Graft Surgery (CABG)

Variable	Prevalence (%)
Patient demographics	
Mean age ± SD (years)	73.7 ± 5.5
Male	64.9
White	92.1
Patient comorbidities	
Congestive heart failure	21.3
Chronic obstructive pulmonary disease	15.3
Cerebral vascular disease	10.4
Diabetes mellitus	3.3
Peripheral vascular disease	8.9
Renal failure	2.9
Previous CABG	2.8
Primary diagnosis of acute myocardial infarction	19.8
Cardiac catheterization on the same day as CABG	9.2
Percutaneous coronary intervention on the same day as CABG	1.0
Intra-aortic balloon pump before CABG	3.0
Admission type	
Transfer into hospital	18.9
Admission through emergency room	18.6
Surgical priority	
Urgent	30.7
Emergent	26.6
30-day or in-hospital mortality	5.4

Similar analyses were conducted for demographic and clinical variables in the MEDPAR data that were independently ($p < 0.01$) related to mortality and for other hospital characteristics, including teaching status (membership in the Council of Teaching Hospitals) and type of ownership (government, for profit, and nonprofit).

Multivariable analyses examined the increase in model discrimination (ie, *c* statistic values) resulting from the

0370
09/15/08

Table 3. Discrimination (as Measured by the C Statistic) of Different Hospital Volume Categorizations for Predicting Mortality at Different Time Points After CABG

Measure of Mortality	Volume as Continuous Variable	Volume as Leapfrog Category (Dichotomous)	Volume as 5 Categories (Quintiles)	Volume as 10 Categories (Deciles)
30-day postoperative or in-hospital	0.53	0.52	0.52	0.53
7-day postoperative	0.53	0.53	0.53	0.53
14-day postoperative	0.53	0.52	0.53	0.53
30-day postoperative	0.53	0.52	0.53	0.53
90-day postoperative	0.52	0.52	0.52	0.53
365-day postoperative	0.52	0.51	0.52	0.52

(Table 1). Unadjusted mortality was directly related ($p < 0.001$) to hospital volume, based on the Leapfrog cutpoint of 256 procedures per year (5.9% versus 5.1%), hospital volume quintiles (6.4%, 5.6%, 5.6%, 5.1%, and 5.0%, respectively), and hospital volume deciles (6.5%, 6.0%, 5.6%, 5.6%, 5.6%, 5.3%, 4.9%, 5.1%, 5.3%, and 4.6%, respectively). Results were generally similar in analyses of risk-adjusted mortality rates (Table 2). Despite the statistical significance of this relationship, the wide variation in mortality rates at individual centers (Fig 1) led to considerable overlap of volume category mortality rate ranges. For example, when examining individual hospitals (n = 870), adjusted mortality ranged from 0.9% to 16.8%, with an interquartile range of 4.5% to 6.9%. Using the Leapfrog cutpoint, risk-adjusted mortality ranged from 0.9% to 16.8% in low-volume hospitals and from 2.0% to 10.6% in high-volume hospitals (Table 2). Of the 660 low-volume Leapfrog hospitals, 253 (38%) had risk-adjusted mortality rates that were similar or lower than the overall risk-adjusted mortality of high-volume hospitals (5.2%). Of the 210 high-volume hospitals, 52 (25%) had risk-adjusted mortality rates that were similar or higher than the overall risk-adjusted mortality (6.1%) of low-volume hospitals. Similarly, 209 (36%) of the 580 hospitals in the lowest two mortality quintiles had risk-adjusted mortality rates that were similar or lower than the overall risk-adjusted mortality of hospitals in the two highest volume quintiles, while 38 (23%) of the 164 hospitals in the highest two volume quintiles had similar or higher risk-adjusted mortality than the overall risk-adjusted mortality rate of hospitals in the two lowest volume quintiles.

Consistent with the overlap in hospital mortality rates, hospital volume alone had relatively poor discrimination for predicting mortality (Table 3). For example, *c* statistics for predicting 30-day or in-hospital mortality and other mortality endpoints ranged from 0.51 to 0.53 for the four approaches to analyzing volume. The *c* statistics for models based on hospital teaching status and ownership were roughly similar (0.51 for all endpoints). In contrast, the *c* statistic for the overall risk-adjustment model based on patient-level risk factors for predicting 30-day or in-hospital mortality was 0.71. The addition of volume to this model increased the *c* statistic marginally (0.002 for volume deciles, 0.002 for volume quintiles, and 0.001 for the Leapfrog volume threshold). Of the 16 patient level variables in the model, 11 (69%) had *c* statistics that were 0.53 or higher.

Comment

On average, higher volume hospitals had lower CABG mortality rates than lower volume hospitals. However,

Table 4. C Statistics for Several Previously Validated Multivariable Models for Risk-Adjusting Coronary Artery Bypass Graft Surgery Mortality Rates

Risk Adjustment Model	Type of Data[a]	Number of Variables	Measure of Mortality	C Statistic

CARDIOVASCULAR

INVITED COMMENTARY

Current thinking is that the informed patient is a better consumer of medical services. In an effort to help the consumer make better decisions related to their care, many groups are offering advice on choosing the best doctors or hospitals. Some groups such as Healthgrades.com or the Texas Health Care Information Council develop algorithms that involve using data from administrative databases, then passing it through a black-box algorithm to generate their rating system.

Others use a more simplistic system tied to factors such as reputation and patient volume. For the *US News and World Report* magazine and USNews.com, volume contributes one third of the final score. Other groups such as the Leapfrog Group use only volume for their recommendations. Using a single univariate analysis, they have decided that the best hospitals have a volume of 450 cases per year in cardiac surgery.

A number of recent publications have challenged the conclusion that using volume alone is a useful measure for determining the best hospitals. This article by Welke and colleagues [1] suggests that using only volume to select the best hospitals (based on mortality rate) is only marginally better than randomly selecting hospitals.

Using the Centers for Medicare Services Medicare Provider and Analysis Review (MEDPAR) part A public files, the authors created a dataset of nearly 1 million patients who underwent coronary artery bypass grafting. They proceeded to look at the relationship between volumes and outcomes (defined as mortality). After dividing the data into groups based on hospital volume using quintiles, deciles, high and low volume (based on Leapfrog criteria), and volume as a continuous variable, they analyzed the mortality rates measured for each group. Although there was a rough correlation of declining 30-day mortality with increasing volume within any group, the range of values nearly totally overlapped the adjacent groups. Further, the "c" statistic, which measures the ability of the model to discriminate accurately, was within the range of 0.51 to 0.53, essentially no better than randomly selecting hospitals (randomness has the value c = 0.50). This poor predictability held even looking at 7,

The Case Against Volume as a Measure of Quality of Surgical Care

Shukri F. Khuri, M.D.,[1] William G. Henderson, Ph.D.[2]

Abstract. Healthcare purchasers, represented by the Leapfrog Group, have attempted to set standards for "quality" of surgical care that include a minimum volume for each of five major surgical procedures, with the assumption that higher volumes in surgery bring better outcomes. The VA National Surgical Quality Improvement Program (NSQIP) is a validated, outcome-based program that prospectively collects clinical data on all major surgical operations in the VA, and builds validated risk-adjustment models that generate, for each hospital and each surgical specialty within a hospital, risk-adjusted outcomes expressed as O/E (observed to expected) ratios for 30-day mortality and morbidity. The O/E ratio has been validated as a reliable comparative measure of the quality of surgical care. Unlike retrospective studies that are based on administrative databases, NSQIP studies have failed to demonstrate a direct relationship between volume and risk-adjusted outcomes of surgery across various specialties. These studies have emphasized that the quality of *systems* of care was more important than volume in determining the overall quality of surgical care at an institution. High-volume hospitals could still deliver poor care in as much as low-volume hospitals could deliver good care. NSQIP studies have also underscored the major limitations of claims data and administrative databases in the provision of adequate risk-adjustment models that are crucial for volume–outcome studies. Therefore, volume should not be substituted for prospectively monitored and properly risk-adjusted outcomes as a comparative measure of the quality of surgical care.

Introduction

The cost of healthcare to employers has been increasing at an alarming pace over the past several years. In 1997, the average cost increase for large employers was 3%; in 2002 it rose to more than 13% (*Business Week*, November 18, 2002). Concerns about increasing costs and patient safety prompted the formation of the Leapfrog Group in 2000. Today, the Leapfrog Group is an alliance conglomeration of more than 150 public and private organizations (most of them Fortune 500 companies) that provide healthcare benefits to more than 34 million healthcare consumers in all 50 states (www.leapfroggroup.org). Recognizing that quality costs less, the group set standards for urban hospitals to meet before they would contract with them for the care of their employees. These "quality" standards included 24/7 coverage in intensive care units by intensivists, implementation of electronic physician order entry, and what was referred to as "evidence-based hospital referrals," a measure based on minimum volume requirements in five major operations that included coronary artery bypass grafting (500/year), esophagectomy (7/year, later increased to 13/year), and abdominal aortic aneurysmectomy (30/year, later increased to 50/year). The Leapfrog Group based its "evidence-based hospital referral" standard on a study by Birkmeyer et al. in which it was argued that more lives would be saved if patients were referred to high-volume as compared to low-volume hospitals [1].

Setting the volume criterion as a measure of *quality* of surgical care, as the Leapfrog Group has proposed, elevates the importance of the volume–outcome issue in surgery and has important implications for care. The purpose of this article is to build the case precisely *against* the use of volume criteria and to promote the use of risk-adjusted outcomes in setting standards for patient safety and quality of surgical care. The issue at hand is much more serious than a mere affirmation of whether increased surgical volume leads to better outcomes or of whether there is a minimum threshold of surgical workload below which the quality of surgical care is compromised. The issue at hand is the attempt, by the Leapfrog Group and others, to institute hospital-specific *quality* score cards based primarily on volume of surgical load. Allowing such standards to prevail means acceptance of the premise that low-volume hospitals deliver substandard care, and that good care can always be delivered by high-volume hospitals. Working from this premise involves passing very important qualitative judgments on specific healthcare provider institutions—judgments that would have far-reaching effects on the economic welfare and professional lives of the medical and paramedical employees at these institutions. In the Veterans Health Administration, the largest single-payer healthcare delivery system in the United States, specific comparative judgments on the quality of care of all 123 major surgical centers are being made by the VA's National Surgical Quality Improvement Program (NSQIP). This communication is based on lessons learned from the NSQIP, which teach us not only that volume of surgical

workload is unrelated to the quality of surgical care, but also that attempts at setting volume as a standard are flawed and, perhaps, more likely to hurt the quality of surgical care than to improve it.

Volume, Outcome, and Quality of Surgical Care in the NSQIP

The NSQIP Metric for the Assessment of the Quality of Surgical Care

The NSQIP is the first national, validated, outcome-based, risk-adjusted and peer-controlled program for the measurement and enhancement of the quality of surgical care that includes a range of surgical subspecialties [2]. It employs risk-adjusted 30-day outcomes of surgery as measures of the quality of surgical care. The NSQIP relies on a trained dedicated clinical nurse reviewer at each institution who uses a standardized protocol to prospectively collect, verify, and transmit to a national data coordinating center data on 52 preoperative patient risk factors (including laboratory variables), 15 intraoperative variables, and 32 thirty-day outcome variables on all major surgery. The NSQIP accrues nearly 105,000 major operations annually. As of September 30, 2003, the NSQIP database comprised data on more than 1.2 million operations in 9 surgical subspecialties. On an annual basis, models predictive of 30-day morbidity and mortality are created for various populations of patients from which, using the logit equation, *expected* morbidity or mortality rates are derived, based on the preoperative severity of illness of specific patient populations. Knowing the actual or *observed* morbidity and mortality rate of a specific patient population, an observed to expected ratio (the *O/E ratio*) for that patient population is then calculated to quantify and provide a comparative measure of the risk-adjusted outcome of that population. Figure 1 shows the O/E ratios for 30-day postoperative mortality of all operations at each medical center as they appeared in the FY2000 Annual Report of the NSQIP. The error bars represent the 90% confidence intervals. The hospitals are identified by code, each facility being privy only to its own code. The O/E ratio ranged from 0 to 2.3. An asterisk denotes a statistically significant high-outlier hospital, meaning that the hospital's mortality rate was significantly higher than expected based on the severity of illness of that hospital's patient population.

The implications drawn from using this method for the comparative assessment of quality of care are that high-outlier hos-

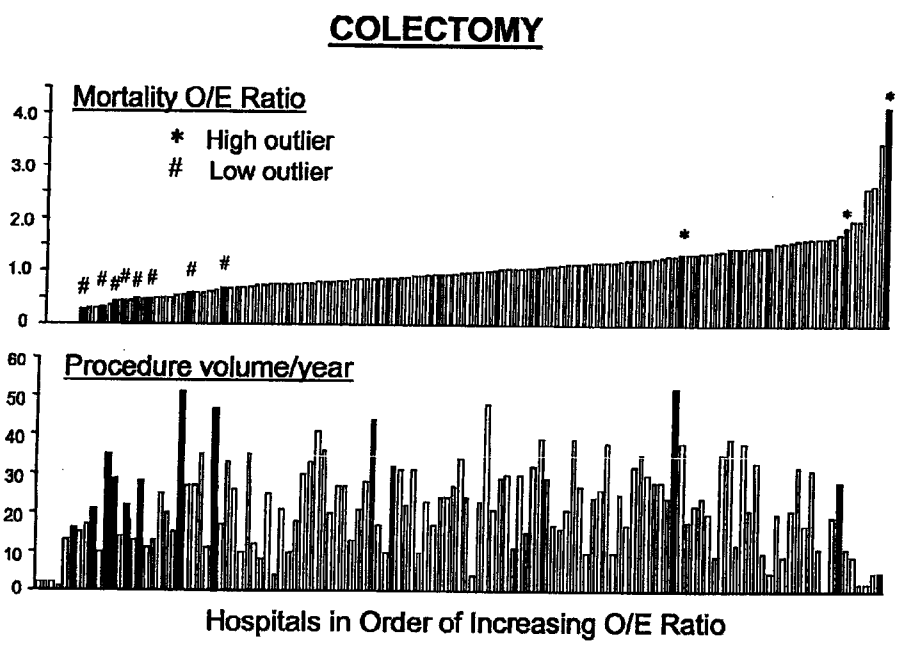

Fig. 2. The top panel shows the 30-day mortality O/E ratios for colectomy in 107 VA hospitals. The bottom panel shows the corresponding annual procedure volume for each hospital. High-outlier hospitals are marked with (*) and low-outlier hospitals are marked with (#).

pitals deliver inferior quality of care and low outlier hospitals deliver superior quality of care. One of the major accomplishments of the NSQIP is that it took these implications about quality of care one step further, conducting a validation study that included site visits by teams of surgeons, health services researchers, and nurses. This validation study demonstrated that, indeed, hospitals with significantly low mortality and morbidity O/E ratios had *superior* structures and processes of care, whereas hospitals with significantly high mortality and morbidity O/E ratios had *inferior* structures and processes of care [3]. The study validated the use of the O/E ratio as a measure of quality of VA surgical care. The NSQIP drives process improvement by feeding back to each surgical service in the VA reliable comparative data that allow providers and managers in these hospitals to compare their performance to that of their peers nationwide, and by identifying best practices in good performing hospitals and disseminating them to all VA hospitals. Since the NSQIP's application in 1991, VA surgery has witnessed a 27% reduction in 30-day mortality and a 45% reduction in 30-day morbidity.

Results of the Volume–Outcome Study

A major study was conducted by the NSQIP to address the debate regarding the regionalization of surgical care to high-volume centers only [4]. Only cardiac surgery and organ transplantation were regionalized in the VA at that time. The VA had been newly reorganized into 22 autonomous networks or Veterans Integrated Service Networks (VISNs), and a new cost allocation system had been implemented which favored primary care over tertiary care. This prompted a number of network directors to recommend closing low-volume surgical services, arguing that better quality surgical care would prevail in higher-volume hospitals. To address this possibility, the NSQIP examined the relation of surgical volume to risk-adjusted outcome in eight common operations: abdominal aortic aneurysm repair, infrainguinal vascular reconstruction, carotid endarterectomy, lung resection (lobectomy and pneumonectomy), open and laparoscopic cholecystectomy, colectomy, and total hip arthroplasty. We used four statistical analyses: (1) a simple Pearson correlation, (2) analysis of variance of risk-adjusted outcomes between hospitals divided in quartiles by volume, (3) mixed effects hierarchical modeling, which accounts for patient and hospital effects, and (4) automatic interaction detection analysis, which looks for a threshold of volume below which outcome is adversely affected. None of the resulting p values in the first three analyses were statistically significant, indicating no relationship between the 30-day mortality O/E ratio and procedure volume in any of the 8 operations examined [4].

Automatic interaction detection, the fourth analysis, also failed to identify a volume threshold below which risk-adjusted 30-day mortality was adversely affected in any of the eight operations. Figure 2 shows the relationship between volume and outcome in 16,181 colectomies performed in 132 VA hospitals. Shown on the top panel are the mortality O/E ratios for colectomy, each bar representing one participating hospital. In this and subsequent illustrations, high-outlier hospitals are marked with (*), and low outlier hospitals are marked with (#). The bottom panel shows the corresponding procedure volume for each hospital. Note that Hospital A, the hospital with the highest procedure volume (52 cases per year), was one of three high outliers, whereas Hospital B, with less than one third of these cases, was the lowest outlier—i.e., the best performer in the entire group.

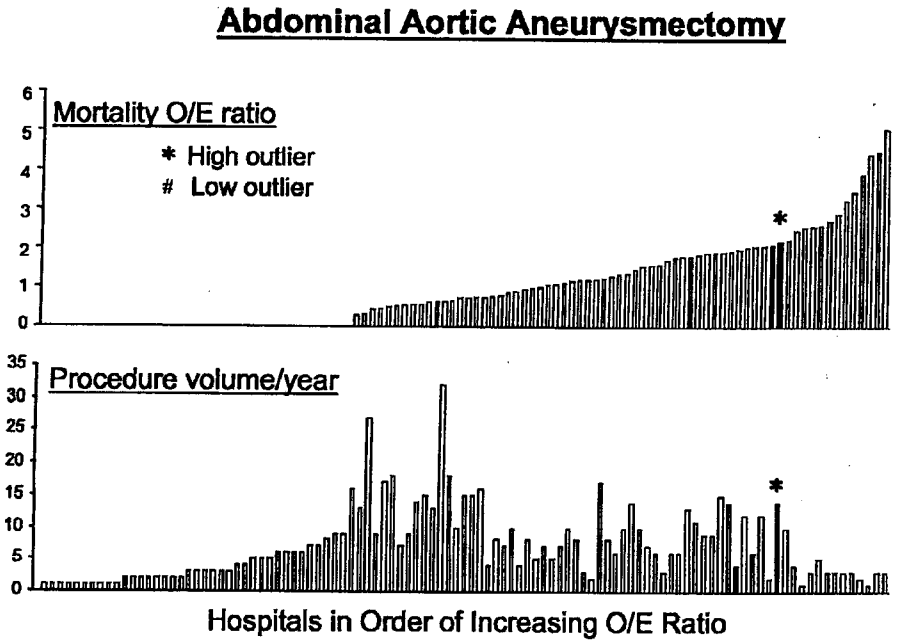

Fig. 3. The top panel shows the 30-day mortality O/E ratios for abdominal aortic aneurysmectomy in 107 VA hospitals. The bottom panel shows the corresponding annual procedure volume for each hospital. There was only one statistically high-outlier hospital (*) in which 14 operations were performed annually.

Additional Observations in Vascular Surgery. The lack of a specific relationship at the hospital level between volume of surgery and the O/E ratio, which the NSQIP has validated as a comparative measure of quality, can be appreciated more by examining the data from the three vascular operations studied. Shown on the top panel of Figure 3 are the mortality O/E ratios for abdominal aortic aneurysmectomy (AAA), again each bar representing one participating hospital. The bottom panel shows the corresponding annual procedure volume for each hospital. Note that there was only one statistically high-outlier hospital (with an O/E ratio of 2.0), which was *not* a low-volume hospital. In fact, this hospital performed more than the group's median number of operations per year. Although the hospitals on the high end of the O/E ratio scale tended to be low-volume hospitals, a relatively large number of low-volume hospitals did not have any mortality during the 3-year period of the study, indicating good performance and giving them an O/E ratio of zero throughout the three years. A scattergram of the same data (Fig. 4) shows the wide variance in the relationship between the number of AAA cases per year per center and the risk-adjusted 30-day mortality rate. Both Figures 3 and 4 show that the only statistically significant high-outlier at the 90% confidence interval was not a low-volume hospital, and that a fairly large number of low-volume hospitals achieved good quality, with O/E ratios of less than 1. Figure 5 shows no correlation between the number of AAA cases per hospital per year and the *expected* mortality rate, which is an indication of the severity of illness of the patient population. Note that a number of low-volume hospitals operated on high-risk patients. The scattergram shows that low-volume hospitals were as likely to operate on high-risk patients as high-volume hospitals were. The same observations were made in comparisons between case load and mortality O/E ratio in carotid endarterectomy (Fig. 6) and infrainguinal reconstruction operations (Fig. 7), where, as another example, a hospital performing 43 operations per year was a statistically low-outlier whereas a similar hospital, performing 47 operations per year, was a statistically high-outlier. Figure 8 again shows no

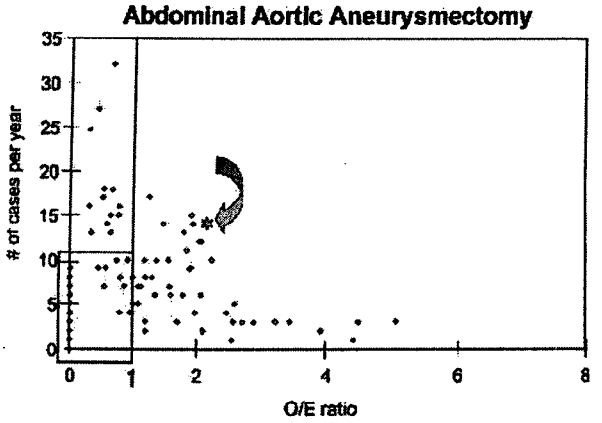

Fig. 4. A scattergram of the same data shown in Figure 3, illustrating the wide variance in the relationship between the number of abdominal aortic aneurysmectomy cases per year per center and the risk-adjusted 30-day mortality rate. The arrow points to the only statistically significant high-outlier hospital. The rectangle in the left corner shows the low-volume hospitals that achieved O/E ratios of less than 1.

0376

obvious direct relationship between the number of infrainguinal reconstructions performed in a hospital and the severity of illness of the respective patient population, as indicated by the expected mortality rate. In fact, the figure shows that the sickest patients were operated on in relatively low-volume hospitals, and that the only high-volume hospital operating on sick patients was a poor performer, with a statistically high O/E ratio.

It is obvious from these data that one would be committing a major error in assuming that surgeons in a relatively low-volume hospital only perform surgery on low-risk patients and cannot achieve good outcomes even in high-risk patients. More importantly, referring high-risk patients to high-volume hospitals does not prevent these patients from having poor outcomes secondary to suboptimal care. Therein lies the fallacy of using the volume standard as the only measure of quality of surgical care.

Limitations of Studies Making the Case for Referral Based on Volume

In light of what we have learned from the NSQIP, we would like now to address critically key studies that have demonstrated a direct relationship between volume and outcome of surgery, in particular the study on which the Leapfrog Group has based its volume standards. Almost all major studies that have found a direct relationship between volume and outcomes in noncardiac surgery have been based on claims and administrative databases. In contrast, the NSQIP, which has failed to show such a relationship, is based on clinical data collected by a trained nurse. The NSQIP has examined whether the information contained in the VA administrative database was adequate for proper risk adjustment of outcomes after surgery. In a recently published study, Best et al. compared patient preoperative variables and 30-day morbidity in the NSQIP database, which they designated the gold standard, to the corresponding variables in the VA's Patient Treatment File (PTF), which they designated the test criterion [5]. The authors calculated both the sensitivity and the positive predictive value of the PTF in depicting risk factors and postoperative outcomes. To justify replacing the NSQIP with the PTF, each of these indicators should have a value equal to or exceeding 0.9. The values obtained were far from 0.9. The average sensitivity and positive predictive value of the PTF in depicting all the preoperative risk factors contained in the NSQIP were 0.27 and 0.34, respectively. Worse still, the average sensitivity and positive predictive value of the PTF in depicting the postoperative outcomes were 0.25 and 0.23, respectively. These findings prompt us to conclude that studies employing administrative databases in the elucidation of the relationship between volume and outcomes of surgery are likely to be flawed because of their inability to adjust adequately for patient severity of illness.

The Leapfrog Group has justified its use of volume criteria by the study of Birkmeyer et al., which attempted to calculate, from previously published studies, the numbers of lives saved if patients in those studies had been referred to high-volume hospitals only [1]. Seventy-five percent of the lives saved were calculated on the basis of two studies that had shown a direct relationship between volume and outcome, one in abdominal aortic aneurysmectomy in the VA [6], and one in CABG in the State of New York [7]. The VA study used by Birkmeyer et al. in their analysis had employed the PTF for risk adjustment. When the NSQIP data on the same patients were analyzed a few years later, no relationship between volume and outcome could be elicited, as stated above. Likewise, the New York State study used by Birkmeyer et al. in their analysis was also supplanted a few years later by a paper by Sollano, from the same group, that showed no relationship between volume and outcome of CABG [8]. Thus, the construct on which the Leapfrog Group has based its volume criteria is at best questionable, and in our opinion, is flawed [9].

A recent study by Birkmeyer et al. [10] based on Medicare claims data showed the mortality rate was higher among patients at low-volume hospitals compared to high-volume hospitals. However, risk adjustment was based on only a few patient risk factors from administrative data, and the models had relatively low C-indexes. Furthermore, their data indicated that large numbers of patients were treated at low- to moderate-volume hospitals, and that many patients and their families would need to be transported at unknown large expense and hardship to satisfy the recommendation that all patients receive treatment at high-volume hospitals.

When in the State of Maryland the Johns Hopkins Hospital reports excellent outcomes in complex surgical procedures, it is probably not because it has the highest volume in the state [11]. Considering that quality is determined first by systems of care, it is more likely that the Johns Hopkins Hospital has the highest volume because it has superior and expert systems of care, which ultimately attract complex and other surgical referrals.

Adverse Impact of Applying the Volume Standard as a Measure of Quality

Using the volume standard as a quality criterion in surgery, as advocated by the Leapfrog Group, is more likely to compromise the quality of surgical care than to improve it: first, it mitigates the chance of assessing and improving systems of care within a specific surgical service. The NSQIP experience, which also includes numerous studies, publications, and site visits to a wide variety of surgical services, has as its premise that quality lies first in well-

0377
09/15/08

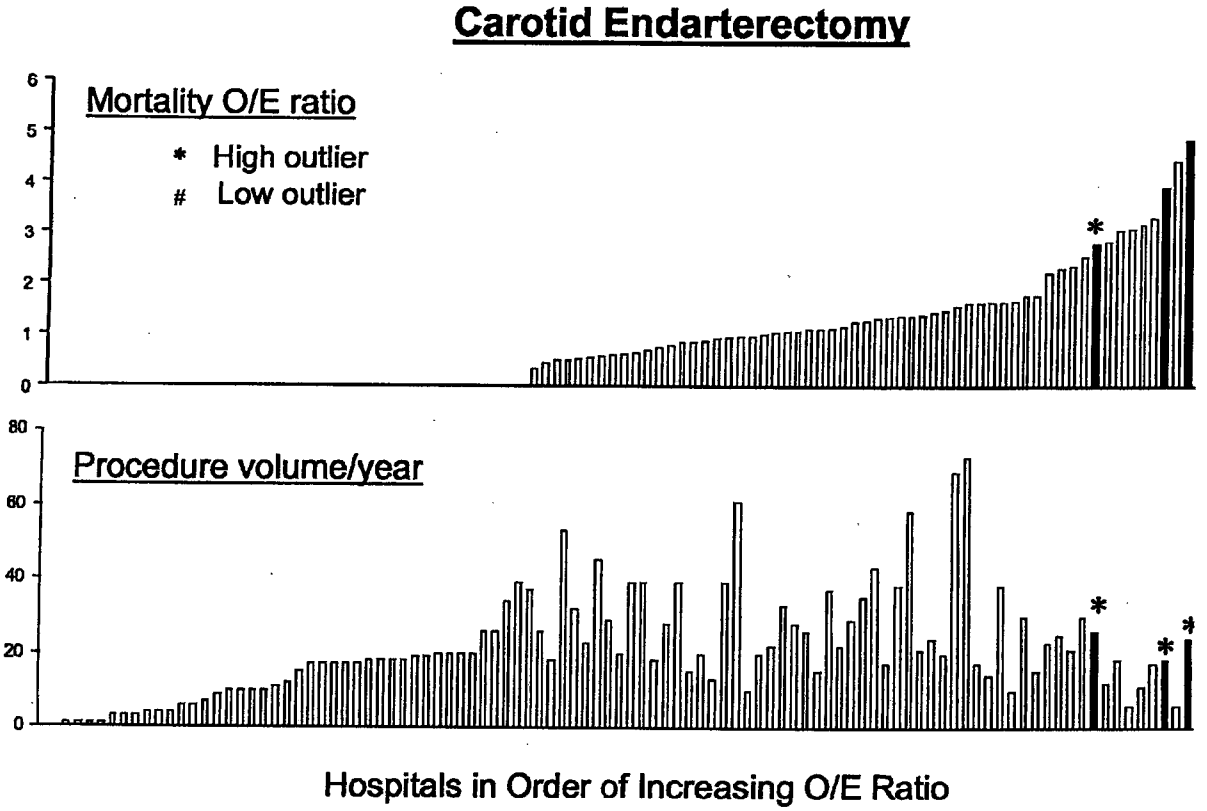

Fig. 6. The top panel shows the 30-day mortality O/E ratios for carotid endarterectomy in the hospitals that reported performing this procedure. The bottom panel shows the corresponding annual procedure volume for each hospital. There were three high-outlier hospitals, indicated by (*); the number of cases performed in these hospitals annually is shown in the corresponding barograph in the lower panel.

coordinated and optimally functioning systems of care. When a specific hospital is identified to be a statistically high-outlier, a methodic analysis of the various systems of care is routinely undertaken to uncover structures and processes that need to be improved. Using the volume standard instead of validated risk-adjusted outcome measures for the assessment of quality passes a potential false judgment on the quality of care of a specific surgical service and, in so doing, mitigates any chance for methodical assessment, and if need be improvement of systems on that service.

Second, applying the volume standard alienates and disenfranchises surgical providers in small hospitals, seriously compromising local quality improvement efforts in surgery in these hospitals. The NSQIP has taught us that efforts to improve the quality of care cannot succeed without the full endorsement and enthusiastic cooperation of the surgeons in the field.

Third, the volume standard cannot be applied to rural hospitals as readily as to urban hospitals. Applying this standard only to urban hospitals, as advocated by the Leapfrog Group, will cause unnecessary hardship to large numbers of patients who would have to travel for long distances to gain access to urban referral centers. It will also rob small hospitals and rural hospitals of their complex elective cases, limiting their experience in the management of these cases and still expecting them to attend to such cases when they present as emergencies, thus potentially compounding the compromise in the quality of surgical care.

Fourth, increasing referrals to high-volume hospitals may tax the capacity of those hospitals to deliver quality care, and thus may result in undesired access issues and poor outcomes of care. As we have demonstrated in the VA, referring patients to relatively high-volume hospitals does not prevent these patients from having poor outcomes and poor quality of care.

Is There a Volume Threshold that Might Influence the Quality of Surgical Care?

In trying to make the case against using the volume standard as a measure of quality, it is impossible to deny that outcomes of systems of surgical care are likely to be adversely affected if the volume of the surgery performed within these systems falls below a certain threshold level. Today, however, that threshold is elusive and very hard to determine. None of us would want to undergo a CABG procedure at an institution that performs only two or three such operations per year. At the crux of the volume-risk-adjusted-outcome relationship in the VA is whether a threshold volume below which quality is likely to be compromised can be determined. The mortality O/E ratio, which is used by the NSQIP as a comparative measure of quality, becomes statistically unsta-

0378
09/15/08

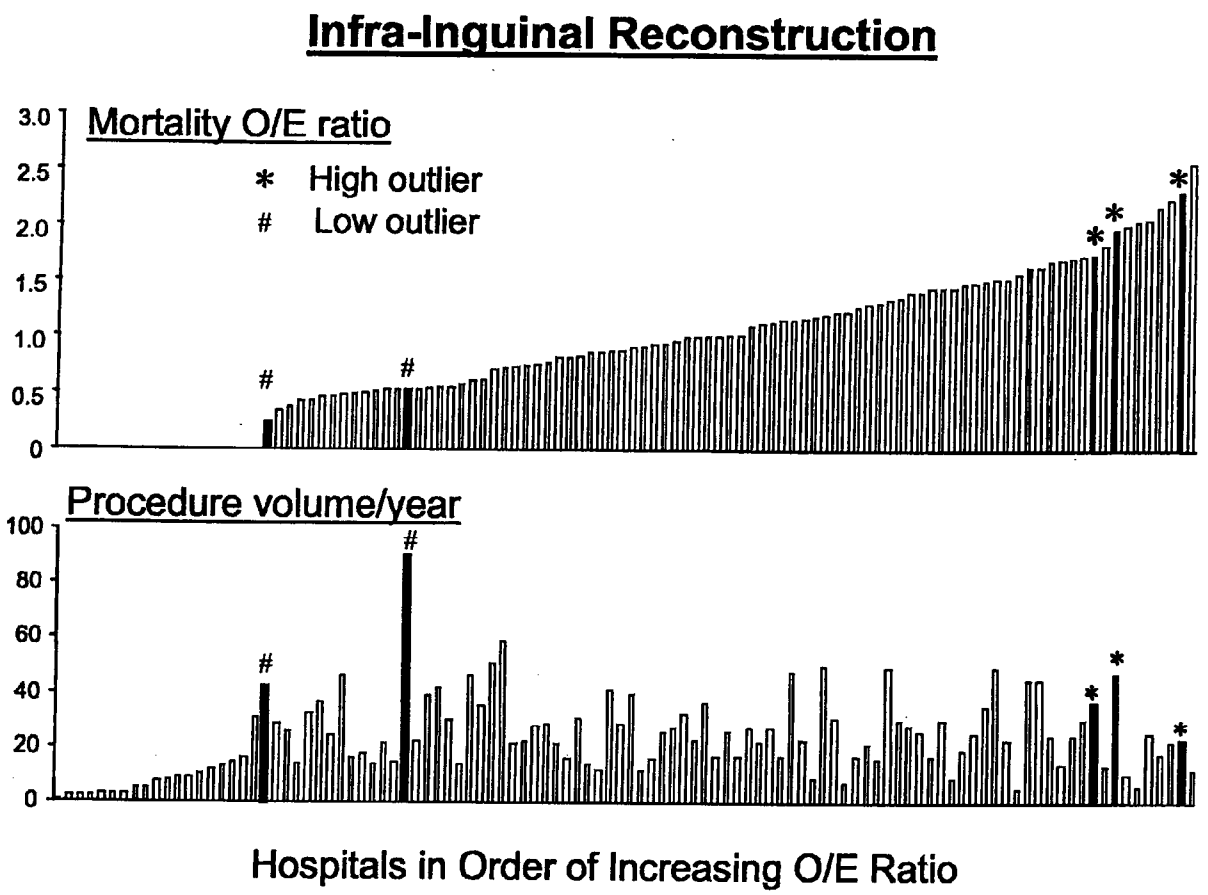

Fig. 7. The top panel shows the 30-day mortality O/E ratios for infrainguinal reconstruction procedures, and the bottom panel shows the corresponding annual procedure volume for each hospital. There were three high (*) and two low (#) outlier hospitals. The number of annual operations performed in each of these five hospitals is indicated in the corresponding barograph in the lower panel.

ble when the sample size is small. Because we found no relationship between volume and outcome O/E ratios in the VA, it is tempting to set as a "volume threshold" the sample size below which the outcome O/E ratio is no longer reliable in reflecting the comparative quality of care. This simple approach gets complicated by the wide variation in outcome event rates between operations and by numerous questions that are yet to be answered. For example, should the volume threshold be based on the total productivity of the system or the provider? Should it be based on numbers performed in a specific operation or on numbers performed within the specialty to which that operation belongs? The clusiveness of identifying valid "volume thresholds" below which the quality of surgical outcomes might be compromised provides another compelling reason for avoiding altogether the use of the volume standard as a measure of quality surgical care.

Conclusions.

1. Volume cannot be a proper measure of quality of surgical care. High-volume hospitals can deliver poor care and low-volume hospitals can deliver good care. Employing volume as a standard will not improve patient safety and is bound to alienate the surgical community and *adversely* affect the quality of surgical care.
2. In surgery, which in most cases revolves around a single episode of care with an expected and a measurable short-term outcome, there is no substitute for the use of properly risk-adjusted outcomes as the primary measures of the quality of surgical care. In this effort, there is also no substitute for the proper prospective acquisition and processing of patient clinical data by dedicated professionals using standardized and validated methodologies.
3. Quality standards in surgery should be set by surgeons, not by industry. The specialty boards in surgery are now struggling with the mandate from the Accreditation Council for Graduate Medical Education (ACGML) and the American Board of Medical Specialties (ABMS) to develop measures of surgeon competence that would be incorporated into the certification and re-certification processes. The American College of Surgeons (ACS) has teamed up with the NSQIP and demonstrated in a $5.6 million study funded by the Agency for Health Re-

0379

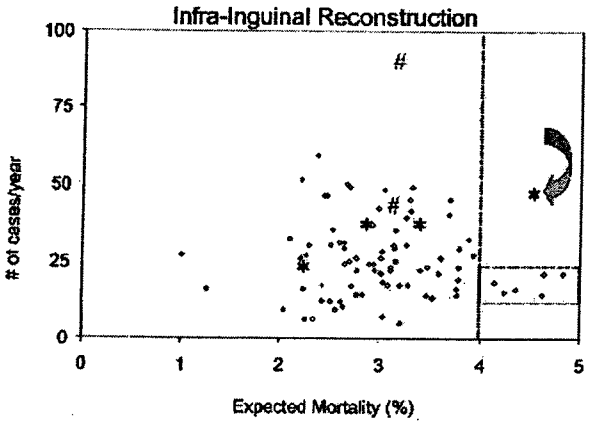

Fig. 8. The relationship between the number of infrainguinal reconstruction procedures per hospital per year and the *expected* mortality rate, which is an indicator of the severity of illness of the patient population. Of the 7 hospitals that had an expected mortality rate of more than 4%, 6 were low-volume hospitals. The seventh (indicated by the arrow) had a relatively high number of operations performed, but was still a high-outlier.

search and Quality that the NSQIP model was applicable to the private sector, as exemplified by 14 major academic community hospitals nationwide. The ACS Board of Regents has recently committed to the establishment of an infrastructure within the ACS that will make the NSQIP available to all hospitals nationwide. Only efforts of this nature have a chance to succeed in setting quality standards for the surgical profession.

4. Although the *raison d'être* for the coming together of the Leapfrog Group is to leverage power in purchasing healthcare, there is no doubt that the member companies genuinely care for the safety and quality of the healthcare of their employees. In that spirit, their employees would be better served if the Leapfrog Group and other groups of purchasers and insurers of healthcare would refrain from setting arbitrary and unvalidated standards for surgical care, and instead would team up with the surgical community in promoting initiatives like the NSQIP. Such collaborative efforts could make it possible for all surgical care provider institutions (whether low or high in volume, urban or rural, government or private) to prospectively collect and transmit reliable clinical patient data that would form the basis for true quality assessment initiatives.

Is Hospital Procedure Volume a Reliable Marker of Quality for Coronary Artery Bypass Surgery? A Comparison of Risk and Propensity Adjusted Operative and Midterm Outcomes

Background. Worse operative mortality has been reported for hospitals with low versus high coronary artery bypass grafting surgery volumes. Despite a lack of comparisons beyond the early postoperative period and evidence of surgeon–volume confounding, some have suggested that regionalization of coronary artery bypass grafting in favor of high volume institutions is warranted.

Methods. We retrospectively compared operative mortality and 3-year survival in coronary artery bypass grafting patients (2001 to 2003) at a low-volume hospital (n = 504; 160 per year [median]) versus a high-volume hospital (n = 1,410; 487 per year) served by the same high-volume surgeon team. Covariate risk adjustment was done via multivariate and propensity modeling.

Results. The two hospital cohorts exhibited multiple demographic and risk factor differences. Unadjusted low-volume hospital vs high-volume hospital operative mortality was similar overall (2.38% vs 2.98%; $p = 0.59$) with nearly identical Society of Thoracic Surgeons observed-to-expected ratios (0.83 vs 0.82), irrespective of preoperative risk category. Hospital volume did not predict operative mortality (odds ratio, 95% confidence interval = 0.82; $p = 0.602$). At follow-up, a total of 28 low-volume hospital deaths (5.6%) and 135 high-volume hospital deaths (9.6%) occurred at similar surgery-to-death intervals ($p = 0.7$). Unadjusted 0 to 3-year survival was significantly worse for high-volume hospitals (risk ratio = 1.59; 1.06 to 2.39; $p = 0.026$). Yet procedure volume was not independently associated with worse midterm survival after covariate (risk ratio = 1.28; 0.84 to 1.96; $p = 0.247$) or propensity score (risk ratio = 1.11; 0.72 to 1.71; $p = 0.648$) adjustment.

Conclusions. Hospital and surgeon volume effects on coronary artery bypass grafting outcomes are interdependent, and therefore hospital coronary artery bypass grafting volume per se is not a reliable marker of quality. Instead, outcome quality markers should rely on thorough risk-adjustment based on detailed clinical databases, possibly including annual and cumulative surgeon volume.

A number of studies have correlated higher coronary artery bypass grafting (CABG) hospital volume to lower associated in-hospital or operative mortality [1–10], or both. It is thus proposed that hospital CABG volume is a reliable marker of CABG quality of care that is easily available to the public. In addition, The Leapfrog Group [11] has recommended that purchasers should preferentially contract with high-volume hospitals (> 450 per year) to avoid the potential for unnecessary deaths. Yet this position is not uniformly shared, and if adopted it will dramatically alter current delivery of cardiac surgery [12, 13]. To temper this, some have suggested that referrals from low-volume to high-volume hospitals should be restricted to high-risk procedures because, commensurate with perceived greater expertise at high-volume institutions, more lives are likely to be saved in such patients [14–18]. Others have found a significant advantage for high-volume hospitals irrespective of operative risk status, and also argue against such an approach [3, 4].

Recently, related studies based on two large clinical databases have reached differing conclusions. Peterson and colleagues [1] analyzed results from 267,089 isolated CABG procedures (2001 to 2002) from 439 United States hospitals participating in The Society of Thoracic Surgeons (STS). They found that hospital volume is only modestly associated with CABG outcome and may not be an adequate marker of surgical quality [1]. Hannan and colleagues [2] and Wu and colleagues [3], reporting on the 1997 to 1999 New York State isolated CABG experi-

ence (N = 57,150), provided compelling data that high-volume hospitals continue to have lower in-hospital mortality [1], and the benefits are similar in low-risk versus moderate-to-high-risk CABG [3]. Importantly, both groups concur that hospital–volume outcome effects are confounded by a significant independent surgeon–volume effect [1–3].

To date, all studies exploring CABG volume effects on outcome have been limited to the consideration of early (in-hospital or 30-day) or operative mortality. Although obviously pertinent, it is not known whether the reported volume–outcome effects persist beyond the early postoperative period. The aims of this investigation were (1) to better define whether procedure volume effects are surgeon or institutional in origin, and (2) to explore whether procedure volume has longer term implications on outcome that extend beyond the early postoperative period. We compared operative (30-day) and midterm (3-year) mortality for two independent institutions served by the same team of high-volume surgeons: (1) a high-volume hospital (HVH) with a cardiac surgery program since 1975, and (2) a newer, smaller low-volume hospital (LVH) program started in 2001. We reasoned that this paradigm would allow us to objectively assess the impact of low versus high institutional CABG volume on outcome free of surgeon–volume confounding.

Patients and Methods

Patients

Study data is derived from the caseload of an experienced 5-surgeon team between January 1, 2001 and December 31, 2003. These surgeons performed a total of 3,115 open-heart operations during this 3-year period at three Toledo, Ohio area hospitals. Surgeon volume averaged 208 open heart operations (median, 178; range, 161 to 285) per surgeon per year. The corresponding number of isolated CABG procedures over this period was 2,269 (73%) including 1,410 done at HVH compared with 504 at LVH. The median (mean) CABG procedures per year were 487 (470) at HVH versus 160 (168) at LVH or approximately 1 to 3 LVH to HVH case-load ratio. The remaining 355 CABG operations were done at a third institution (data not analyzed; see Discussion).

All consecutive patients undergoing isolated CABG at LVH and HVH were analyzed. Patients were excluded if they had concomitant valve, other cardiac, or carotid surgery. The same perfusion team provided cardiopulmonary bypass services at LVH and HVH. With rare exception, normothermic bypass combined with cold blood cardioplegia was utilized for CABG at both hospitals. Off-pump CABG was similarly used at the two institutions (HVH versus LVH = 5.3% versus 4.2%; $p = 0.34$) with similar selective criteria. All patients had a valid United States social security number. The institutional review boards at both institutions approved research based on ongoing clinical cardiac surgery databases. The requirement for informed consent was waived.

Clinical Data and End Points

Clinical data on patients undergoing revascularization have been systematically abstracted and recorded in identical cardiac surgery databases at both hospitals. Both institutions participate in The STS national cardiac surgery database. The primary end points were all-cause operative mortality (30-day or in-hospital, whichever is longer) and 0 to 3-year mortality. The Social Security Death Index (conducted in August 2004) was used to determine timing of death used for mid-term survival analysis. Allowing for a 3-month lag, this corresponds to a follow-up between 5 and 41 months.

Statistical Analyses

Continuous data were expressed as mean ± standard deviation. Baseline variables were compared by using the Wilcoxon rank-sum test, *t* test, or the chi-square test as appropriate. Actual operative mortality (OM), risk-adjusted and observed-to-expected ratio of operative mortality data are reported as per the latest STS CABG risk model [19]. In addition, for LVH versus HVH, we used two tests to compare (1) overall OM and (2) OM for three STS risk-based sub-cohorts: (1) low risk (< 2%), (2) moderate risk (2% to 5%), and (3) high risk (> 5%). Effects of explanatory variables on OM were derived by logistic regression.

Low-volume hospital versus HVH midterm Kaplan-Meier [20] survival for the entire cohort and for the low, moderate, and high-risk cohorts were compared with (Breslow test) and without (log rank test) weighting. For the Breslow test, each test is weighted by the number of patients at risk in each of the comparison groups at any given time. Next, multivariable Cox proportional-hazards regression [21, 22] was done to assess the effects of explanatory variables on long-term mortality and their associated risk ratios. Regression model selection was done with backward elimination (Wald statistic, confirmed using forward and stepwise selection).

Potential confounding due to the unbalanced LVH versus HVH patient variables on outcome comparisons cannot be discounted, even after multivariate risk adjustment [23, 24]. To minimize these effects, we utilized LVH propensity score analysis derived via a nonparsimonious logistic regression model (LVH = 1, HVH = 0) [23, 24]. All

0382
09/15/08

the variables listed in Table 1 and their significant interactions were included in this model. The score was then incorporated into subsequent multivariate model analyses as a covariate. In case of OM, the population was divided to LVH propensity score quintiles and compared. A $p < 0.05$ cutoff was used to indicate significance (SPSS version 10.0, SPSS Inc, Chicago, IL).

Results

Demographics, Risk Factors, and Operative Data

The HVH and LVH cohorts exhibited similar gender and age distributions, whereas the majority of their preoperative risk factors and operative variables were significantly different (Table 1). African-Americans accounted for 7% of HVH patients versus only 1% of LVH patients, and more HVH patients were on Medicaid or uninsured. The LVH patients were characterized by a greater incidence of obesity, family history of coronary disease, angina, triple-vessel disease, emergent CABG, greater number of grafts, and consequently relatively longer bypass. Alternatively, the HVH cohort included more smokers (past and current), diabetes, insulin dependence, hypercholesterolemia, renal failure, dialysis dependence, hypertension, cerebrovascular disease, peripheral vascular disease, chronic obstructive pulmonary disease, myocardial infarction, unstable angina, as well as history of previous cardiovascular intervention including redo surgery. The relative imbalance in preoperative morbidity led to a significantly greater HVH cohort STS predicted mortality risk (HVH, 3.59%, LVH, 2.90%; $p < 0.001$).

Operative Mortality

Unadjusted OM was similar for the two hospitals (HVH vs LVH, 2.98% vs 2.38%; $p = 0.59$) (Table 2). The corresponding observed-to-expected ratio of mortality data of The STS risk model were 0.83 and 0.82, respectively. Separate comparisons of the low, moderate, and high-risk subgroups also indicated similar OM results for HVH and LVH irrespective of risk category. Hospital volume was not among the OM predictors by logistic regression, which included increasing age, longer cardiopulmonary bypass, insulin dependence, cerebrovascular disease, chronic obstructive pulmonary disease, emergencies, redo surgery, all-vein grafting, and coronary endarterectomy (see Table 3). Forcing hospital volume (HVH = 0, LVH = 1) as a covariate did not alter model prediction (OR = 0.82; range, 0.40 to 1.71; $p = 0.60$) as illustrated by the receiver operator characteristic curve comparison (Fig 1). Individual surgeons and Medicaid and uninsured status did not predict OM.

Midterm Survival

A total of 163 deaths (8.5%) have been documented in this CABG series including 28 of 504 LVH deaths (5.6%) and 135 of 1,410 HVH deaths (9.6%). Time of death for LVH (median, 37 days; interquartile range, 11 to 516 days) and HVH (median, 134 days; interquartile range, 23 to 433 days) was similar ($p = 0.7$). Follow-up in surviving patients was significantly shorter for LVH versus HVH (median, 621 days; interquartile range, 469 to 958 days vs median, 806 days; interquartile range, 537 to 1,064 days; $p < 0.0001$). This difference was largely due to the systematically increasing number of patients per year between 2001 and 2003 at LVH compared with a relatively unchanged HVH annual volume.

Unadjusted LVH versus HVH Kaplan-Meier survival for as much as approximately 1,100 days post-CABG are shown in Figure 2 (top); this indicated a significantly worse HVH survival (risk ratio, 95% confidence interval = 1.59; range, 1.06 to 2.39; $p = 0.026$ log rank and 0.020 Breslow). The LVH survival was superior at 1 year (95.6% vs 93.1%) and 3 years (91.5% vs 87.8%). The low STS risk LVH cohort showed a significantly better survival (Fig 2, bottom). Covariate adjustment via Cox regression analysis showed that hospital volume was not a significant predictor of 0 to 3-year mortality (Fig 3, top) (risk ratio = 1.28; range, 0.84 to 1.96; $p = 0.247$). Individual surgeons and Medicaid and uninsured status did not predict survival. The multivariate predictors of increased midterm mortality are detailed in Table 4, and these included increased age, vein only grafting, preoperative renal failure, longer cardiopulmonary bypass, preoperative myocardial infarction, chronic obstructive pulmonary disease, obesity, small patient size, diabetes, cerebrovascular disease, and congestive heart failure.

Propensity Analysis

For LVH patients, the median (interquartile range) LVH propensity score (0 = HVH, 1 = LVH) was 0.36 (range, 0.22 to 0.52) compared with 0.18 (range, 0.10 to 0.28) for HVH patients. The C-statistic (area under the receiver operator characteristic curve) for the propensity score model was 0.77, indicating good discrimination power (Fig 4). The LVH versus HVH OM across propensity score cohort quintiles showed no systematic or significant differences (Fig 5). Last, Cox regression analysis of 0 to 3-year survival using hospital and propensity score as the only covariates resulted in propensity score ($p = 0.0004$) being the only predictor of mortality, whereas hospital volume (risk ratio = 1.11; $p = 0.648$) was not (Table 4) (Fig 3, bottom). Using propensity scores, we were able to match 378 of 504 LVH patients (75%) to unique HVH matches. Kaplan-Meier survival for the propensity-matched HVH and LVH sub-cohorts were similar (risk ratio = 1.07; $p = 0.29$).

Comment

We demonstrate that, when served by the same high-volume surgeon, similar CABG operative and midterm (3-year) outcomes may be achieved in low-procedure volume institutions (LVH, a suburban community hospital) and high-procedure volume institutions (HVH, an urban community hospital). For 3-year data, we found that the unadjusted 0 to 3-year Kaplan-Meier survival after CABG was significantly better for LVH (Fig 2), but these differences are eliminated by risk-adjustment (Fig

Moderate (2–5%)	10/443, 2.26%	2/135, 1.48%	0.84
High (> 5%)	25/235, 10.6%	9/63, 14.3%	0.62

O/E = observed to expected ratio; OM = operative mortality; STS = The Society of Thoracic Surgeons.

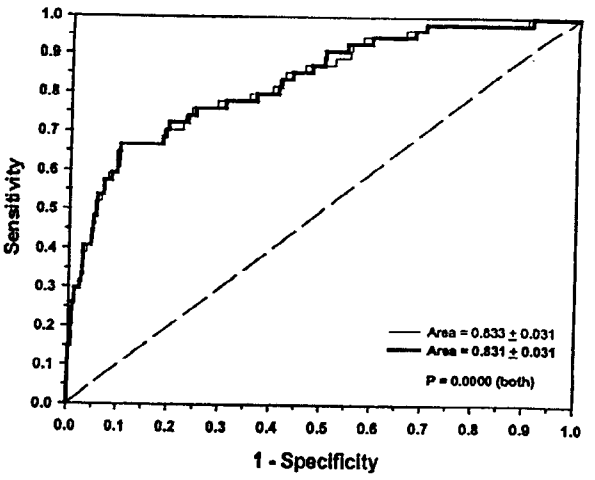

Fig 1. Receiver operator characteristic curve for predicting operative mortality for all patients as determined from logistic regression model (see Table 3) applied to all patients (thick line). *Forcing hospital (low-volume hospital = 1; high-volume hospital = 0) variable into the model did not significantly alter the model prediction power* (thin line).

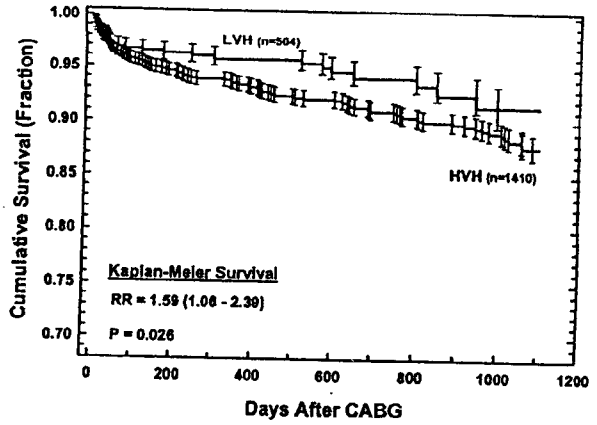
3). These results were also confirmed by a non-parsimonious (ie, patient variables were included in the model irrespective of significance level) propensity score model analysis, which is less susceptible to residual confounding, or unaccounted for confounding [23, 24].



The role of hospital-procedure and surgeon-procedure volumes on CABG outcomes have been investigated by many [1–18]. With few exceptions [12, 13], studies had indicated that higher CABG surgery hospital and surgeons volumes are associated with lower mortality rates [1–10]. Consequently it was reasoned that a significant number of CABG deaths may be avoided if a policy of "regionalization" is adopted to avoid low-volume hospitals [14–18]. However, implementation of such procedure-volume guidelines may be unwarranted from a number of perspectives: (1) they equate low-volume hospitals with good outcomes to those of poorer quality of care; (2) they assume similarly higher quality of CABG care in all high-volume hospitals relative to all smaller programs; and (3) they do not, as has been proposed, appropriately account for potentially substantial surgeon-volume confounding effects [1–3]. Another concern is that a regionalization policy may cause significant disruption in the current delivery of care with thousands of patients being referred away from low-volume to high-volume hospitals. To ease this, some have recommended that such referrals be limited to high-risk patients [14], yet the appropriateness of this approach was recently challenged [2, 3].

Table 3. Predictors of Operative Mortality by Multivariate Logistic Regression Applied to All 1,914 Patients (Low-Volume Hospital and High-Volume Hospital Cohorts Combined)

Variables in the Equation	Odds Ratio	95.0% Confidence Interval	p Value
Constant	0.00		0.0000
Cardiopulmonary bypass (per 10 min increments)	1.15	1.08–1.21	0.0000
Emergency/salvage	4.45	2.03–9.76	0.0002
Age (per 10 yr increments)	1.58	1.03–1.09	0.0002
All vein grafting	3.77	1.72–8.27	0.0009
Chronic obstructive pulmonary disease	2.39	1.31–4.36	0.0047
Redo surgery	3.26	1.42–7.49	0.0052
Cerebrovascular disease	2.35	1.24–4.47	0.0090
Insulin-dependent diabetes	2.21	1.07–4.58	0.0320
Coronary endarterectomy	2.10	1.01–4.37	0.0482

Many prior studies exploring CABG volume–outcome effects relied on unadjusted (or incompletely adjusted) early or operative mortality that are easily accessible from administrative databases. Also, many of these analyses predicted worse CABG outcomes in small compared with large hospital programs [1–10]. It is noteworthy that the LVH versus HVH differences we found in unadjusted 0 to 3-year mortality (including a slightly lower [not significant] unadjusted OM in LVH patients) are contrary to these predictions. From the 1994 to 1999 national Medicare claims data, Birkmeyer and colleagues [5] showed a 1.3% absolute drop in CABG unadjusted OM from very low-volume (< 230) to very high-volume hospitals (≥ 850). Operative mortality of Medicare patients at low-volume hospitals (3.95%) and high-volume hospitals (4.08%) were similar. Hannan and colleagues [2] analyzed the clinical data from 30 New York State centers between 1997 and 1999, and they noted significantly decreased OM in high-volume compared with low-volume hospitals even after risk adjustment. Their statewide study is among the most complete analyses based on clinical data, yet only a small minority (< 3%) had their CABG done at low-volume centers due to New York State restrictions. A subsequent analysis of their data

(Bottom) Comparison of unadjusted Kaplan-Meier survival for low-volume versus high-volume hospital in risk-based sub-cohorts (low-risk, moderate-risk, and high-risk) based on the latest Society of Thoracic Surgeons (STS) risk model [19]. (See Results section for details.)* (Error bars = *standard error.)* (CABG = *coronary artery bypass grafting;* RR = *risk ratio.)*

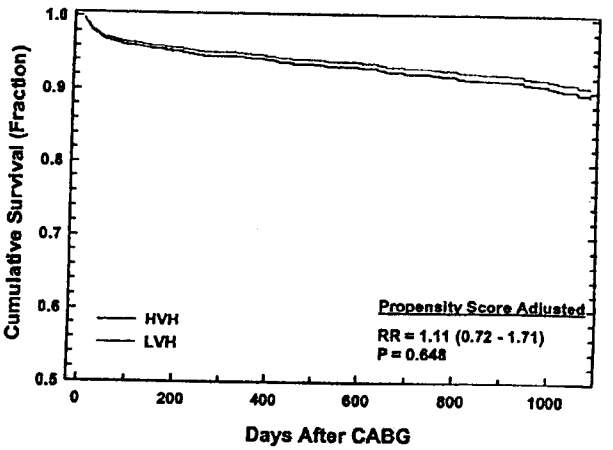

Fig 3. Risk-adjusted 0 to 3-year survival for low-volume hospital (LVH) versus high-volume hospital (HVH) derived by Cox proportional hazard regression analysis with multiple other risk factor and demographic covariates (top) and non-parsimonious propensity model score as a single covariate of hospital volume (bottom). Model predictors are shown in Table 4. (CABG = *coronary artery bypass grafting;* RR = *risk ratio.)*

showed that these volume effects were true for both low-risk as well as moderate-to-high-risk patients [3]. This was also true for our analysis (Table 2, Fig 1).

In contrast, Peterson and colleagues [1] analyzed the 2000 to 2001 isolated CABG outcomes of all participating hospitals in The STS national database. Although they reported a modest yet persistently greater operative mortality in low-volume programs, they concluded that hospital volume is not an adequate marker of quality of CABG care, and that other more clinically rigorous quality assessment instruments should be preferred [25]. They also indicated that the hospital–volume outcome effect was particularly nonsignificant in young (< 65 years) and low operative risk CABG patients. Our results do not conform to this STS analysis, despite the fact that both our institutions' data are included in their analysis.

Evidence that surgeon volume is a major confounding factor of hospital volume, CABG outcome effects were also presented in the New York State [2, 3] and The STS national [1] studies. The similar LVH and HVH outcomes we report for the same high-volume surgeon team implied that worse CABG outcomes in low-volume hospitals reported by others [1–10] may reflect low surgeon volume rather than hospital volume effects. Consequently, low-volume programs served by low-volume versus high-volume surgeons may be associated with significantly different outcomes.

As described in the Methods section, the same surgeon team also performed cardiac surgery at a third low-CABG volume institution (355 CABG for 2001 to 2003). This data was not included in the primary analysis to avoid potential confounding factors. First, 90% of all CABG procedures were performed by 2 of 5 surgeons (Table 1). Second, at this hospital, an independent perfusion team was utilized at this site, and nearly 35% of the

isolated CABG cases were done off-pump compared with about 5% at LVH and HVH. Third, nursing, anesthesia, and intensive care staffs were shared with other services. Last, the teaching aspect of this institution led to greater involvement of physicians from other services as well as greater input of residents and fellows in patient care. Importantly, despite these differences, the unadjusted OM (2.8%; 10 of 355) and observed-to-expected ratio (0.77) were similar to that of LVH and HVH (Table 2). These results at an even smaller and distinctly different cardiac surgery program underscore our primary result that institutional volume may not be an accurate marker of CABG quality, and argue in favor of surgeon experience being the more critical factor.

Limitations of the study include the fact that our practice is representative of only a subset of current practice paradigms in which the same surgeon team is entirely responsible for cardiac surgery at multiple independent hospitals including both low-volume and high-volume programs. Although this eliminated surgeon-volume confounding effects, it also limits the general applicability of the findings. The described LVH and HVH programs are independent institutions with signif-

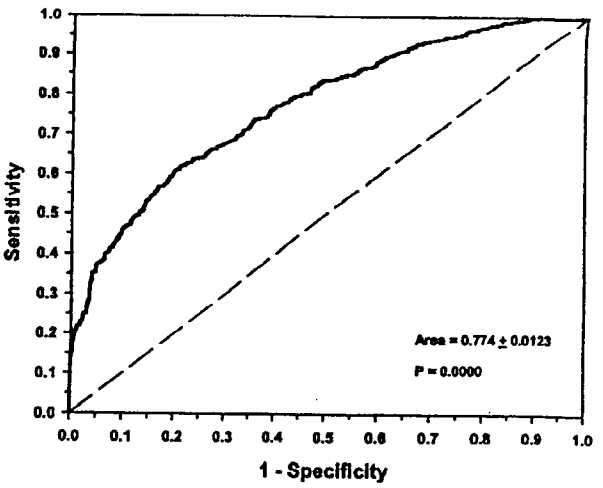

Fig 4. Receiver operator characteristic curve of low-volume hospital (LVH) propensity score as a predictor of LVH actual patients (high-volume hospital [HVH] cohort: 0.204 ± 0.138; LVH cohort: 0.431 ± 0.274; p < 0.0001). The propensity score is based on a non-parsimonious logistic regression model utilizing the variables listed in Table 1. The area ± standard error under the receiver operator characteristic curve was 0.774 ± 0.0123 (p < 0.0001) indicating good discrimination.

icant differences as well as important similarities that may contribute to outcomes. Briefly the HVH program is long-established (30 years) at an urban hospital and meets the high-volume Leapfrog Group criteria, whereas the LVH is a smaller suburban low-volume community hospital with roughly one third the procedure volume. Both hospitals have committed substantial resources including dedicated personnel, cardiovascular anesthesia, and operating rooms, as well as intensive care and step down units. Nursing and surgical assistant teams were similarly trained with equivalent operational guidelines.

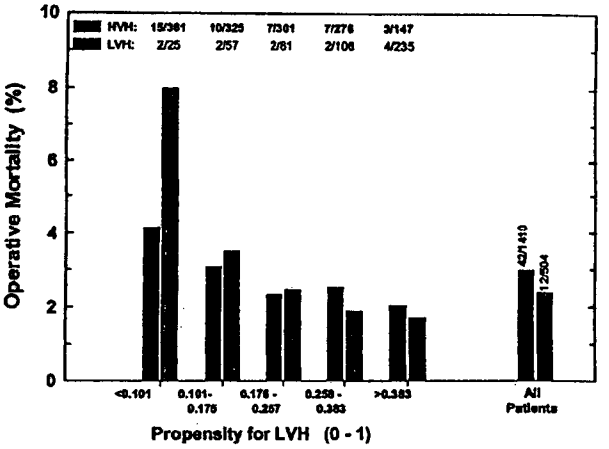

Fig 5. Comparison of low-volume hospital (LVH) versus high-volume hospital (HVH) unadjusted operative mortality in propensity score quintile groups. Overall operative mortality comparisons were shown for reference.

Yet their experience is distinct with about 50% of the nursing staff working at both hospitals. Surgical assistant overlap is minimal. The same perfusion team conducted all cardiopulmonary bypass duties at both institutions. There is no overlap in anesthesia.

The scope of this study and the similar procedure volumes among the surgeon team members do not allow for a meaningful direct assessment of surgeon volume effects. Annual surgeon volume, which was controlled for in our analysis, is only one measure of surgeon experience. Indeed, the question of whether the cumulative surgeon volume occurring over many years is a more appropriate volume measure, or at least should be concomitantly considered, was not addressed here or in any other study. Accordingly, future analyses should attempt to address the following question: Is annual surgeon volume equally important in determining quality of care for surgeons with many years of experience versus less experienced surgeons? Our study is not designed, nor sufficiently powered to address this question; all surgeons had comparable annual volumes.

In summary, when the same surgical team applies similar patient care standards and critical pathways, and emphasizes a team approach to cardiac surgery care, it is possible to achieve similar operative and midterm CABG outcomes at independent low-volume or high-volume cardiac surgery programs. Our analysis emphasized the importance of appropriate risk adjustments if comparisons are to be meaningful, which is only possible through detailed clinical databases [1, 25–28]. In conclusion, we find that hospital-volume and surgeon-volume effects are interdependent, which suggests that CABG outcomes are likely to be distinctly different for low-volume hospitals served by low-volume surgeons as opposed to high-volume surgeons. Therefore, hospital CABG volume per se should not be solely used as a marker of surgical quality. Instead, outcome quality markers should rely on thorough risk-adjustment, including surgeon volume factors. An analysis of CABG outcomes for all low-volume hospitals participating in The STS national database that includes annual (and possibly cumulative) surgeon volume as a covariable is warranted to unequivocally address this contention.

This research was supported by Saint Vincent Mercy Medical Center (Toledo, OH) institutional and departmental funds.

INVITED COMMENTARY

In this article, Zacharias and associates report a review of coronary bypass surgery experiences in a single geographic area in which a group of five surgeons operated at four different hospital systems. When the risk-adjusted survival outcomes from three of these hospitals of varying surgical volumes were compared, the authors concluded that hospital and surgeon volumes were not predictors of mortality.

This is an extremely important and timely contribution, as the authors address a statistical database controversy relating to hierarchical modeling. With this type of statistical approach, a model is developed in which the impact of the experience and quality of the surgeon and the experience and quality of the hospital setting are interrelated. The decision to apply or not apply this type of modeling has been a raging issue within the statistical and epidemiological and public health arenas. This type of distinction is important and very germane to reporting results in cardiothoracic surgery. Simply stated, with this type of modeling, the impact of a given surgeon's skill and the outcome parameters related to the hospital staff, systems, and resources are separated with the magic of a hierarchical or nested modeling technique.

Many reports have included dozens of hospitals and hundreds of surgeons, either validating this author's conclusion or reaching the opposite conclusion regarding the importance of surgeon and hospital-volume interaction. Many carefully done non-hierarchical prior studies have shown that poorly performing low-volume hospitals and surgeons achieve poor results and that high-volume hospitals and surgeons generally obtain better results. The questions arise as to outcome when a low volume, less skilled surgeon practices in either a high-volume excellent hospital system or a low-volume less excellent hospital. The opposite situation, when a high-volume excellent quality surgeon practices in either a high-volume excellent hospital system or a low-volume less excellent hospital is also problematic. Simply stated, is it possible to separate the surgical skill and experience from the staff-related and system-related parameters that determine surgical mortality and morbidity by using a risk-adjusted statistical model.

So, why should we care? Why is this so timely and deserving of the attention of all American heart surgeons? The United States Department of Health and Human Services and its health care major payer, The Centers for Medicare and Medicaid Services (CMS), the agency which guides national Medicare and Medicaid reimbursement and sets the stage for many commercial and managed care payers, has widely "discussed" that they will pursue a strategy known as "pay for performance." As such, the health care reimbursement dollar will be adjusted such that hospital and physician providers achieving statistically better outcomes, as defined by The National Quality Forum (NQF) and CMS standards, will be financially incentivized. When working within a budget-neutral reimbursement environment, those surgeons and hospitals achieving poorer outcomes, again as defined by CMS and NQF standards, will be paid less.

Clearly, hospitals and physicians have always wanted their outcomes to be optimal, to provide the highest quality patient care while serving all sectors of the payer mix. However, in an era of falling reimbursement and progressively tighter health care dollars, how these outcomes are calculated and how the hospital and physician components come together will likely come under great focus.

What should we do? Understanding is an important first step. To be sure that you and your health care systems understand that the data collection and reporting mechanisms are important and work to make them accurate and timely. To press for a robust data validation and auditing system so that all start from a level playing field of data accuracy. To explore multiple types of statistical models based on the outcome parameters of more than simply perioperative death, but long-term survival, postoperative events, and quality of life. Finally, to work with your health care system to understand those outcome predictors that may be unique to your specific working environment, and truly optimize care aimed at quality and patient safety. After all, eliminating outcome differences based upon volume, hospital resources, and surgical care is what we are all about!

Procedural Volume as a Marker of Quality for CABG Surgery

Eric D. Peterson, MD, MPH
Laura P. Coombs, PhD
Elizabeth R. DeLong, PhD
Constance K. Haan, MD
T. Bruce Ferguson, MD

Context There have been recent calls for using hospital procedural volume as a quality indicator for coronary artery bypass graft (CABG) surgery, but further research into analysis and policy implication is needed before hospital procedural volume is accepted as a standard quality metric.

Objective To examine the contemporary association between hospital CABG procedure volume and outcome in a large national clinical database.

Design, Setting, and Participants Observational analysis of 267 089 isolated CABG procedures performed at 439 US hospitals participating in the Society of Thoracic Surgeons National Cardiac Database between January 1, 2000, and December 31, 2001.

Main Outcome Measure Association between hospital CABG procedural volume and all-cause operative mortality (in-hospital or 30-day, whichever was longer).

Results The median (interquartile range) annual hospital-isolated CABG volume was 253 (165-417) procedures, with 82% of centers performing fewer than 500 procedures per year. The overall operative mortality was 2.66%. After adjusting for patient risk and clustering effects, rates of operative mortality decreased with increasing hospital CABG volume (0.07% for every 100 additional CABG procedures; adjusted odds ratio [OR], 0.98; 95% confidence interval [CI], 0.96-0.99; $P=.004$). While the association between volume and outcome was statistically significant overall, this association was not observed in patients younger than 65 years or in those at low operative risk and was confounded by surgeon volume. The ability of hospital volume to discriminate those centers with significantly better or worse mortality was limited due to the wide variability in risk-adjusted mortality among hospitals with similar volume. Closure of up to 100 of the lowest-volume centers (ie, those performing ≤150 CABG procedures/year) was estimated to avert fewer than 50 of 7110 (<1% of total) CABG-related deaths.

Conclusion In contemporary practice, hospital procedural volume is only modestly associated with CABG outcomes and therefore may not be an adequate quality metric for CABG surgery.

JAMA. 2004;291:195-201 www.jama.com

THE ASSOCIATION BETWEEN HOSpitals' coronary artery bypass graft (CABG) surgery volume and outcome has been the subject of multiple investigations.[1-17] Based on these studies, the Center for Medicare & Medicaid Services (CMS) and the Leapfrog Group have proposed using hospital volume as an indicator of CABG quality.[18-20] Prior studies of the association between volume and outcome, however, generally have been based on administrative data sources, have reflected selected patient populations, and often have not adequately accounted for patient case mix, patient clustering, and other methodological concerns. Before hospital surgery volume is accepted as a standard quality metric, further research into issues related to both analysis and policy implication is warranted.

We undertook a contemporary examination of the association between hospital CABG procedural volume and outcome using clinical data available from the Society of Thoracic Surgeons (STS) National Cardiac Database. Specifically, we considered whether hospital CABG volume was associated with operative mortality after accounting for patient case mix. Second, we examined the extent to which patient clustering within centers and site variance issues affected this association. Third, we determined how the association varied as a function of patient age and predicted surgical risk. Fourth, we determined whether the association between hospital volume and outcome was influenced by individual surgeon volume. Finally, we investigated the potential health policy implications of using hospital volume as a quality indicator. This included determining the ability of hospital volume to discriminate high-mortality outliers, as well as investigating the potential number of lives saved if low-volume centers were systematically closed.

For editorial comment see p 246.

METHODS

Data Source

The STS National Cardiac Database was established in 1989 to report surgical outcomes following cardiothoracic surgical procedures.[21-23] The database cur-

rently captures clinical information from nearly two thirds of all US bypass procedures from more than half of all centers performing adult cardiac surgery. Sites enter patient data using uniform definitions (available online at http://www.sts.org) and certified software systems. This information is sent semiannually to the STS Data Warehouse and Analysis Center at the Duke Clinical Research Institute. There, a series of data quality checks are performed before a site's data are aggregated into the national sample. While participation in the STS database is voluntary, data completeness is high, with overall preoperative risk factors missing in fewer than 5% of submitted cases.[24] The accuracy of submitted data has further been confirmed in independent comparison of hospital CABG surgery volume and mortality rates reported to the STS vs those reported to the CMS.[24]

Patient Population

We examined isolated CABG surgery procedures, excluding those combined with valve or other major surgical interventions, performed between January 1, 2000, and December 31, 2001, at hospitals reporting to the STS. We excluded 12 centers (2.7% of total STS centers) that reported fewer than 30 CABG procedures in a year and that had evidence for incomplete reporting. Inclusion of the 223 cases from these 12 centers had no measurable impact on the study's measured association between CABG procedural volume and outcome.

Statistical Analysis

Our primary outcome measure was all-cause operative mortality, defined as in-hospital or 30-day mortality, whichever was longer. Major morbidity was defined as any of 5 postoperative in-hospital complications: stroke, reoperation for any reason, need for mechanical ventilation for more than 24 hours following surgery, renal failure, or deep sternal wound infection.[25]

Hospital-isolated CABG annual case volume was averaged over a 2-year period (2000 and 2001) to increase its stability. In the overall analysis, volume was considered to be a continuous variable. For display purposes, patient and hospital characteristics and unadjusted outcomes were categorized by annual hospital procedural volume (≤150, 151 to 300, 301 to 450, and >450). These break points were chosen to form 4 fairly equal-sized hospital samples while maintaining similar volume differences among the groups.

The effect of hospital volume on unadjusted outcomes was tested using standard logistic regression. Expected mortality rates for patients were calculated using a logistic regression model that included 28 previously identified preoperative risk factors[25] and year of surgery. The C-index for this model in the study population was 0.78. Risk-adjusted mortality rates for each hospital were calculated by dividing the observed mortality rate by the expected mortality rate at the hospital and multiplying by the overall (national) bypass mortality rate. Additionally, hierarchical logistic regression was used to account for patient clustering within centers (SAS Macro GLIMMIX).[26] These analyses included clinical risk factors, procedure year, and hospital procedural volume as a fixed effect and included random intercepts for sites. To supplement this analysis, a hospital-level weighted least-squares regression of risk-adjusted mortality on volume was used to correct for nonconstant variance associated with hospital sample size, as reflected by hospital volume.[27] This method assigned greater weight to observations with smaller variance.

Because many previous studies have focused on Medicare populations (ie, those with patients aged ≥65 years) while others have specifically investigated the effect of hospital volume as a function of patient risk,[13,15] we also tested for interactions between hospital volume and patient age (<65 years and ≥65 years) and expected risk for patients in our hierarchical analyses. We also used our hierarchical analysis to test the hospital volume × surgeon volume interaction. While the STS database does not contain the names of individual surgeons, it does contain an encrypted primary surgeon identifier that can be aggregated within and among hospital locations to approximate annual surgeon volume.

Finally, we also examined health policy implications of hospital volume. We first determined the degree to which hospital volume identified "mortality outlier" hospitals as determined by their significance in a hierarchical logistic regression model containing patient characteristics but not volume. Specifically, we used a hospital-level standard logistic regression model to test whether hospital procedural volume could discriminate mortality outliers. Second, we assessed the potential number of lives saved from closure of either the lowest hospital volume quartile in the STS database (≤150 CABG procedures per year), or alternatively using the Leapfrog-proposed referral criteria of fewer than 500 procedures per year.[28] In these calculations, we assumed that all these patients could safely be transferred from low- to higher-volume centers without risk and that the patients would assume the expected risk predicted for the higher-volume site once there. All statistical analyses were performed using SAS release 8.2 (SAS Institute Inc, Cary, NC), with $P<.05$ considered statistically significant.

RESULTS

Between 2000 and 2001, 267089 isolated CABG procedures were performed at 439 STS hospitals. Average hospital procedural volumes ranged from 39 to 1754 isolated CABG procedures (median, 253; interquartile range, 165-417). Eighteen percent of STS centers performed 500 or more procedures per year.

TABLE 1 displays patient and hospital characteristics as a function of hospital volume. Compared with higher-volume centers, lowest-volume hospitals (ie, those performing ≤150 procedures per year [n=98]) were more likely to operate on nonwhite patients, as well as on patients with chronic lung disease, prior stroke, recent myocardial infarction, left main artery disease, and

0391
09/15/08

emergent or salvage settings. Based on preoperative risk factors, the average expected surgical mortality risk ranged from 3.0% for hospitals performing 150 cases or fewer to 2.6% for those performing more than 450 cases. The Pacific and West South Central regions tended to have more low-volume hospitals per region, while New England, and the Mid-Atlantic, South Atlantic, and East South Central regions had more high-volume centers.

Hospital Volume and Outcomes

Overall, there were 7110 deaths (2.66%). Overall unadjusted mortality declined from 3.5% for hospitals in the lowest-volume group to 2.4% for hospitals in the highest-volume group ($P<.001$ for trend) (TABLE 2). Rates of prolonged ventilation and renal failure also declined significantly ($P<.001$ for both) with increasing hospital procedural volume. Reoperation, stroke, and rates of deep sternal wound infection were generally constant across volume group, as was postoperative length of stay (median, 5 days for all volume groups).

After adjusting for preoperative clinical risk, year of surgery, and patient clustering within centers, hospital mortality declined significantly as a function of hospital procedural volume, ranging from 3.1% for centers performing 150 or fewer cases per year to 2.4% for those performing more than 450 cases per year. When looking at hospital volume as a continuous variable, absolute rates of mortality decreased by 0.07% for every 100 additional CABG cases per year (adjusted odds ratio [OR], 0.98; 95% confidence interval [CI], 0.96-0.99; $P=.004$).

Although the relationship between hospital procedural volume and risk-adjusted mortality was statistically significant, there was wide variance in results observed among individual centers, particularly in the low-volume category (FIGURE 1). While part of this variance is inherent, due to sample-size effects, the association between hospital volume and outcome persisted after correcting for nonconstant variance among sites by means of weighted least squares ($P=.001$).

Effect of Volume on Outcome in Patient Subgroups

The absolute effect of hospital volume was more apparent in elderly patients (FIGURE 2). In patients aged 65 years and older, there was a 1.0% difference in observed mortality rates between low- (≤150) and high-volume (>450) hospitals that was only slightly diminished after adjustment for risk ($P<.001$). In contrast, among those younger than 65 years, observed mortality declined by only 0.3% and was insignificant after adjustment for risk ($P=.53$).

Similarly, patients with intermediate and high expected preoperative risk demonstrated consistently lower mortality when treated at higher-volume centers (TABLE 3). In contrast, among those with expected operative risk of less than 1.5%, there was no volume effect in either observed or adjusted mortality rates. A formal test for volume × patient risk interaction in the logistic regression model was significant ($P=.002$).

Surgeon and Hospital Volume

TABLE 4 demonstrates the effect of hospital and surgeon volume on risk-adjusted operative mortality rates. While there was colinearity between

these factors, both surgeon volume and hospital volume were significant predictors of mortality. Combined, the highest mortality rates (3.3%) were observed when patients were treated by low-volume surgeons at low-volume hospitals and best results (2.4%) were obtained by high-volume surgeons at high-volume hospitals.

Figure 1. Risk-Adjusted Hospital Mortality Rates by CABG Procedural Volume

Each dot represents a hospital reporting data to the Society of Thoracic Surgeons National Cardiac Database. CABG indicates coronary artery bypass graft.

Figure 2. Unadjusted and Risk-Adjusted Mortality by Patient Age Group

Error bars indicate 95% confidence intervals. CABG indicates coronary artery bypass graft.

Policy Implications

The use of hospital procedural volume was of limited value in discriminating those hospitals with significantly better or worse risk-adjusted mortality outcomes ("outlier centers") (C-index, 0.60 and 0.67, respectively). In fact, as procedural volume dropped, a hospital's likelihood of being singled out as a center with significantly better or worse outcomes declined due to increasing variance associated with the measurement of end point at low-volume sites.

An upper boundary for the potential numbers of lives saved by closure of low-volume CABG centers was also estimated. If 25% of STS hospitals with the lowest annual CABG volume (≤150 procedures) were closed and their patients undergoing CABG surgery were safely transferred to another, higher-volume center, then approximately 45 CABG procedural deaths could be averted annually among all 439 STS centers. If the criteria for selective referral were based on Leapfrog's referral criteria of 500 cases per year,[18] 82% of STS centers would close and the high-end estimate of avertable CABG deaths would be 212 per year.

Validity of STS Data

In order to determine the validity of STS data for patients aged 65 years and older, we performed a systematic comparison with data supplied to the CMS. There were 415 centers that released data to the STS and the CMS; more cases (96330 vs 78788) were reported to the STS, likely due to nonreporting of health maintenance organization and managed care cases to the CMS. The reported mortality rates were 4.50% and 4.48%, respectively. Reported mortality rates among centers that performed 150 or fewer procedures per year were 5.06% and 4.91% according to the STS and the CMS, respectively, while corresponding rates for centers that performed more than 150 cases per year were 4.39% and 4.35%. Thus, we

†Results further adjusted with risk group to ensure constant risk profiles.

doubt that our results were biased by underreporting or selective reporting to the STS.

We also systematically compared mortality rates among participants and nonparticipants in the STS. Mortality rates in participating sites were lower (4.5% vs 5.2%), but the differential mortality between lower-volume sites (≤150 CABG procedures/year) and higher-volume sites (≥151 CABG procedures/year) was larger in the STS sites than in nonparticipating sites (0.6% vs 0.1%, respectively). Thus, the association between volume and outcome may have been overestimated by focusing on STS sites.

COMMENT

The recent interest in using hospital procedure volume as a quality indicator for CABG surgery is understandable. This structural characteristic is readily available via administrative claims data, requires no complex adjustment techniques, is easily interpretable by the lay public, and is consistent with the common belief that "practice makes perfect."[20] However, our study indicates that hospital volume has only a modest association with risk-adjusted mortality and has important limitations as a quality metric for CABG surgery.

To date, there have been multiple analyses of volume and outcome for CABG surgery. Most[1-15] but not all[16,17] of these concluded that hospital procedural volume was associated with lower rates of hospital mortality. The largest analysis of the association between volume and outcome was conducted by Birkmeyer et al.[14] Using national Medicare claims data from 1994 to 1999, they found a 1.3% absolute difference in unadjusted rates of mortality between the lowest to highest quartiles of hospital volume.[14] While their study was geographically inclusive, it was limited to patients aged 65 years or older, could not adequately adjust data for potential differences in case mix, and did not control for patient clustering within sites or for site variance issues.

*Mortality rates are presented as percentages.
†Accurate assessment not possible due to insufficient overlap of high-volume surgeons in hospitals with very low procedural volume.

One of the most complete evaluations of CABG volume-outcome relationships performed using clinical data was completed by Hannan et al.[9] Using data from 30 centers performing CABG surgery in New York from 1997 to 1999, the study by Hannan et al also noted significant differences in risk-adjusted mortality among low- and high-volume hospitals. The study, however, was limited to a single state where a strict certificate-of-need program limits the number of low-volume centers (ie, <3% of all patients receive CABG surgery at centers performing <300 procedures per year).

Our contemporary analysis using clinical data from the STS National Cardiac Database found an association between procedural volume and unadjusted mortality similar to that found in past analyses. Our study, however, expanded on these prior analyses using contemporary analytic techniques to properly account for clinical factors, differences in site variability, and clustering within sites. We found that, compared with high-volume hospitals, low-volume hospitals tended to operate on patients with higher risk and under more emergent conditions (Table 1). Reasons for these differences may include adverse selection,[7,10] variance in clinical coding among hospitals, or a differential threshold for surgery due to altered center experience and/or institutional financial pressure.

We also found that the association between hospital volume and mortality was not constant among all patients. In particular, the volume-outcome effect was nonsignificant in patients younger than 65 years and in those with low preoperative risk (Figure 2, Table 3). These results imply that prior analyses performed exclusively in Medicare patients would

Downloaded from www.jama.com at St Mary's Hospital, on May 22, 2007

0394
09/15/08

inflate the volume-outcome effect. Additionally, it is presumed that while young, low-risk patients would be the group most likely to use public information from CABG quality metrics, these are also the patients in whom hospital volume had no measurable association with outcome.

We further demonstrated that associations between hospital volume and outcome were confounded by the concomitant effects of surgeon volume (Table 4). These results expand those previously reported from a single state[9] to a national cohort. Even if a patient elected to receive surgery at a high-volume center, their risk-adjusted mortality rates could vary from 2.4% to as much as 2.9%, depending on whether or not their actual procedure was performed by a low- vs a high-volume surgeon.

Our study further demonstrates the limitations of using hospital volume as an indicator of the quality of CABG surgery. Hospital volume had generally poor predictive accuracy as a means of identifying hospitals with significantly better or worse CABG mortality rates (C-index, <0.7). Similarly, using volume as a sole referral criterion for selecting a provider would unfairly defer cases from nearly half of very–low-volume centers with outcomes equal or better than overall STS mortality results (Figure 1).

Regardless of its value at the level of the individual center, some still have argued for using hospital-volume limits for their "aggregate societal good." A study from California estimated that up to 27% of deaths at low-volume centers may be averted with selective referral.[29] In contrast, our study estimated that the total number of lives saved by eliminating up to 100 low-volume STS hospitals (25% of total sites) would be less than 1% from deaths (n=45). If Leapfrog-proposed referral criteria of 500 or more cases per year were applied, up to four fifths of STS sites would be closed while fewer than 3% of national STS CABG mortality events would potentially be averted.

This study does not fully preclude the use of procedural volume in certain roles. In particular, the small but consistent association between hospital procedural volume and outcomes should be considered when prospectively determining the need for new programs.[30] Additionally, given that quality assessment based on comparison of risk-adjusted outcomes is limited at low-volume sites due to wide 95% CIs surrounding their outcome estimates, it seems reasonable to monitor low-volume centers using trend analyses of multiyear adjusted outcomes to ensure quality of care.

Several limitations should be noted. While this study represents the largest clinical evaluation of hospital volume to date, the STS National Cardiac Database currently collects data from roughly half of all US surgical centers. Participating centers tend to be larger and have slightly better outcomes than nonparticipating centers. However, unadjusted results in this study were similar to those from prior studies. Our evaluation of surgeon volume was limited to a blinded proxy and may underestimate this impact. Third, while our study indicated that low-volume centers may have been more willing to operate on higher-risk patients, it could not determine whether this lower threshold for case selection was indicative of better or worse patient care. Further study of the appropriateness of case selection by hospital volume would be indicated. Finally, our study was not designed to isolate specific clinical mechanisms for the association between volume and outcome. Differences in surgical teams, quality of postoperative care, surgical techniques, and other unmeasured factors all may contribute to the effect observed in this study.

In this national study we found that hospital procedural volume was only modestly associated with risk-adjusted CABG mortality rates; however, there were many low-volume hospitals with low mortality rates and some high-volume centers with rates higher than expected. This study suggests that hospital CABG surgery volume is best considered as a surrogate for quality in a setting where other more direct process and outcome assessments are not available.[20] Instead it seems more reasonable to support the continued growth of national clinical databases, which are capable not only of tracking risk-adjusted surgical care patterns and outcomes, but also of improving them.[23,31]

Author Contributions: Dr Peterson, as principal investigator of this study, had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analyses.
Study concept and design: Peterson, DeLong, Haan, Ferguson.
Acquisition of data: Peterson, Ferguson.
Analysis and interpretation of data: Peterson, Coombs, DeLong, Haan.
Drafting of the manuscript: Peterson, Coombs.
Critical revision of the manuscript for important intellectual content: Peterson, Coombs, DeLong, Haan, Ferguson.
Statistical expertise: Peterson, Coombs, DeLong.
Obtained funding: Peterson, Ferguson.
Administrative, technical, or material support: Ferguson.
Study supervision: Peterson.
Role of the Sponsor: This study was sponsored by the Society of Thoracic Surgeons (STS). Specifically, the Duke Clinical Research Institute (DCRI) has a contract with the STS to be their National Cardiac Data Warehouse and Analysis Center (Dr Peterson, principal investigator of this subcontract). In this role, the DCRI independently harvests data from each participating STS center, creates a national analysis database, and performs statistical analyses. The proposal for this study was submitted by Dr Peterson to the STS national database publications committee (a 6-member board representing both the STS and the DCRI). After approval, the manuscript was reviewed by the coauthors and a final version approved by the publications committee.

Abstract

Background: The Leapfrog Group recommended that coronary artery bypass grafting (**CABG**) surgery should be done at high volume hospitals (>450 per year) without corresponding surgeon-volume criteria. The latter confounds procedure-volume effects substantially, and it is suggested that high surgeon-volume (>125 per year) rather than hospital-volume may be a more appropriate indicator of CABG quality.

Methods: We assessed 3-year isolated CABG morbidity and mortality outcomes at a low-volume hospital (LVH: 504 cases) and compared them to the corresponding Society of Thoracic Surgeons (**STS**) national data over the same period (2001–2003). All CABGs were performed by 5 high-volume surgeons (161–285 per year). "Best practice" care at LVH – including effective practice guidelines, protocols, data acquisition capabilities, case review process, dedicated facilities and support personnel – were closely modeled after a high-volume hospital served by the same surgeon-team.

Results: Operative mortality was similar for LVH and STS (**OM**: 2.38% vs. 2.53%), and the corresponding LVH observed-to-expected mortality (**O/E** = 0.81) indicated good quality relative to the STS risk model (O/E<1). Also, these results were consistent irrespective of risk category: O/E was 0, 0.9 and 1.03 for very-low risk (<1%), low risk (1–3%) and moderate-to-high risk category (>3%), respectively. Postoperative leg wound infections, ventilator hours, renal dysfunction (no dialysis), and atrial fibrillation were higher for LVH, but hospital stay was not. The unadjusted Kaplan-Meier survival for the LVH cohort was 96%, 94%, and 92% at one, two, and three years, respectively.

Conclusion: Our results demonstrated that high quality CABG care can be achieved at LVH programs if 1) served by high volume surgeons and 2) patient care procedures similar to those of large programs are implemented. This approach may prove a useful paradigm to ensure high quality CABG care and early efficacy at low volume institutions that wish to comply with the Leapfrog standards.

09/15/08

Background

For many years investigators have studied the relationship between the outcomes of high procedure-volume institutions with those of low procedure-volume institutions. This has been especially true for coronary artery bypass grafting (CABG) surgery with varied results [1-11]. Indeed, recent studies have indicated that low volume-procedure institutions performing CABG surgery may have good outcomes particularly if associated with high volume surgeons (> 125 cases per year) [12-15].

In this report we review our experience with a recently initiated small community hospital cardiac surgery program modeled after a similar high volume practice in the region. In this paradigm a group of high volume cardiac surgeons expanded their practice, protocols, and procedures to include the smaller institution. We reasoned that this paradigm can be used successfully by low volume hospitals. We tested this contention by comparing the operative and midterm results of an LVH to the national data as reported for the Society of Thoracic Surgeons (STS) National Cardiac Database over the same period.

Methods

Patients

We retrospectively reviewed the initial 504 patients of a new cardiac surgery program undergoing isolated CABG between February 1, 2001 – December 31, 2003 at Saint Luke's Hospital (Maumee, Ohio), a 189-bed community hospital in Northwest Ohio. The information was extracted from a local database. Patients were excluded if they had concomitant valve, other cardiac, or carotid surgery. Institutional Review Board approval was obtained for this ongoing clinical cardiac surgery database research. The requirement for informed consent was waived by the Institutional Review Board.

Clinical data / end points

Clinical data on patients undergoing revascularization have been systematically abstracted and recorded in a dedicated cardiac surgery database, and are regularly reported to the STS national cardiac surgery database. The primary end points were operative mortality and morbidity (complications and length of hospital stay), and those were compared to the STS 2001–2003 data. In addition, LVH 0- to 3-year all-cause mortality for survival data was collected and combined via the Social Security Death Index (conducted in August 2004). Allowing for a 3-month lag, this corresponds to a follow-up between 5 and 41 months.

Statistical analysis

Continuous data were expressed as mean ± SD. Baseline variables were compared by use of the Wilcoxon rank-sum test, t-test, or the χ^2 test as appropriate. Actual, risk-adjusted and observer-to-expected operative mortality (OM, Adj. OM, and O/E, respectively) data are reported as per the latest STS CABG risk model [16]. Effects of explanatory variables on OM were derived by logistic regression. Survival was compared with Kaplan-Meier analysis (log rank test) and multivariable Cox proportional-hazards regression. The latter was done to assess the effects of the varying death hazard on long-term mortality predictors and their associated risk ratios (RR). Regression model selection was done with backward elimination (Wald statistic – confirmed using forward and stepwise selection). A $P < 0.05$ cutoff was used to indicate significance (SPSS version 10.0, SPSS Inc., Chicago, IL).

Results

A total of 504 CABG procedures were performed in the initial 35 months of this new cardiac surgery program. This LVH population demonstrated a similar distribution of age and gender to that of the STS, whereas race and body mass index differed significantly (Table 1). Our LVH patients had a higher incidence of three vessel disease, obesity, preoperative myocardial infarction and family history of coronary artery disease. The STS cohort exhibited more peripheral vascular disease, chronic obstructive pulmonary disease, angina, preoperative renal failure, hypercholesterolemia, congestive heart failure, and trended toward more cerebral vascular accidents ($p = .06$). These differences in preoperative morbidity led to a lower STS predicted mortality risk in our population, 2.94% vs. 3.13%. The LVH cohort had a relatively greater incidence of emergencies, use of internal mammary arteries, use of intra-aortic balloon pumps, and blood transfusions. The incidence of elective cases, redo surgery, and off-pump procedures were less than the STS. Total CPB (cardiopulmonary bypass) and cross-clamp times were shorter.

Our LVH operative mortality (OM) did not statistically differ from the STS (2.38% vs. 2.53%). The corresponding O/E morality ratio was 0.81 and adjusted OM was 1.9%. Multivariate OM predictors were age, emergency status, and time on cardiopulmonary bypass (Table 2). The patients in the very low risk (<1%) and low risk (1–3%) categories fared better than the STS with actual mortality rates and O/E mortality ratios of 0%, 0.0 and 0.9%, 0.52, respectively. The moderate to high-risk category (>3%) had an actual mortality rate (7.3%) and an O/E mortality ratio (1.03) that were comparable to the STS.

Compared to the STS data, post-operative complications of leg wound infection, prolonged ventilation, renal dysfunction (no dialysis), and atrial fibrillation occurred more frequently at our LVH (Table 3). Also, LVH had a greater rate of 30-day readmissions. However, total length of stay, post-operative length of stay, post-operative

Ejection fraction was available in 464 patients. CV intervention = any cardiovascular intervention (surgery, angioplasty, or stenting). The urgent cases (197/504) are not compared in the STS database.

ventilator hours, strokes, sepsis, pneumonia, urinary tract infection, and sternal wound infection were similar.

Unadjusted Kaplan-Meier survival was 96%, 94 %, and 92% at 1, 2, and 3 years, respectively (Figure 1), which was comparable to the STS. Effects of six patient variables on survival are shown in Figure 2. Gender and diabetes did not affect midterm survival, while survival for older (> 65 years) patients, cerebral vascular disease, longer time on CPB, and higher STS predicted operative mortality risk all exhibited significantly worse midterm survival.

Predictors of 0–3 year mortality were derived by multivariate (proportional hazard) Cox regression analysis and included longer time on CPB (RR = 1.15), all vein grafts (RR = 5.74), cerebral vascular disease (RR = 3.79), age (RR

= 1.63 per 10 years), redo surgery (RR = 3.46), and congestive heart failure (RR = 2.48). Preoperative renal failure approached significance (RR = 3.81, p = .078) (Table 4).

Discussion

While many researchers have found hospitals with higher CABG volumes to be associated with better outcomes, there has been significant interest in the potentially confounding influence of cardiothoracic surgeon procedure-volumes on this association [1,2,5,11,13-17]. Four states (California, New York, New Jersey, and Pennsylvania), which represent a quarter of the US population, have rigorous reporting systems for CABG procedures based on risk-adjusted mortality alone. In these states the Leapfrog standard includes only those hospitals in the top quartile. These "top" hospitals had overall mortality rates of 1.7% compared with 4.1% in the lower quartiles. In the rest of the nation, volume (>450 cases per annum) and mortality rates below 2.7% comprise the Leapfrog standard [18]. The use of standard risk-adjusted mortality rates may become the benchmark if rigorous outcomes measurement systems are implemented throughout the United States. Risk adjustment makes surgeon procedure volume very important. In this way, certain cases may be restricted to particular procedure volume surgeons, thus patient redistribution to regional centers may not be necessary.

Three recent studies of note have highlighted the critical importance of surgeon procedure volume [13-15]. Peterson et al found that hospital procedure-volume, as a quality marker in CABG surgery, was to be only modestly associated with risk-adjusted CABG mortality rates [14]. In fact, these researchers clearly identified many low-volume hospitals with low mortality rates and several high

0400
09/15/08

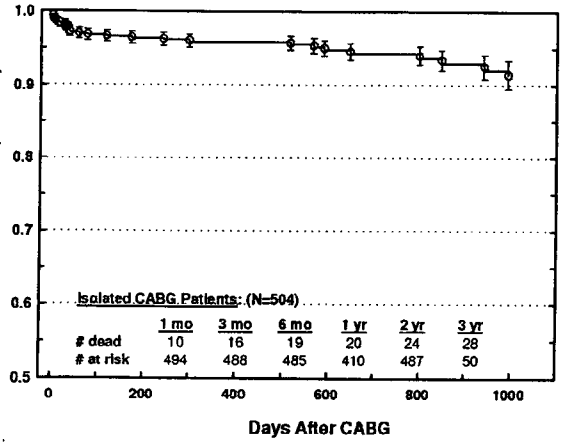

Figure 1
Kaplin-Meyer survival curve for 504 LVH CABG patients. Bars = standard error.

volume centers with higher than expected rates. In addition, Wu et al indicated that high volume cardiothoracic surgeons were associated with a lower risk of death for both low-risk and moderate-to-high risk CABG patients [15] and Birkmeyer et al demonstrated that the observed associations between hospital volume and operative mortality were modulated by surgeon volume [13].

The establishment of the STS National Cardiac Database has facilitated quality of care comparisons of cardiac surgery programs relative to national statistics [19-21]. The Center for Medicare and Medicaid Services (CMS) and the Leapfrog group have suggested that hospital volume be used as the indicator of the quality of CABG outcomes [22-24]. However, an insightful review of the evidence by Shahian and Normand lends merit to the argument that CABG surgery is so pervasive that its well-recognized techniques and well-understood pathophysiology make provision for its transportability to low volume institutions in the hands of skilled, high volume surgeons [25]. The recent Peterson et al investigation of the STS database accounted for clinical factors, differences in site variability and clustering within sites. They documented that (1) low volume institutions tended to operate more often on patients under emergent conditions, (2) the association between hospital volume and mortality was different for younger (<65 years) vs. older (>65 years) patients, (3) the hospital volume and outcome associations were confounded by the concomitant effect of surgeon volume, and (4) hospital volume per se was a poor predictor of CABG outcome [14].

In view of the above studies the issue of volume as a "proxy" yields itself to discussion. Some have criticized hospital volume as a crude indicator of surgical quality in that hospital volume is only a proxy for low mortality (high quality) [26-29]. Volume must be examined from the perspective of, not only the hospital, but also of the surgeon. The procedure volume of surgeons is an important proxy for quality CABG care. In this light, our example of a high quality, low volume center should not be unexpected, especially when our LVH used high volume surgeons.

Our study site was a small, low procedure volume hospital located in an increasingly affluent suburban community with a large rural catchment area. This accounted for the large number of Caucasians and the under-representation of African-Americans. The increased body surface area and excessive obesity that occurred in our population was to be expected according to findings that indicate Ohio is near the leading edge of the obesity experience in the United States [30,31]. The study site patients had more significant family histories of coronary artery disease (CAD), but we cannot comment as to the extent of the effect of genetic predisposition versus social impact (overeating, smoking, lack of exercise) had upon this finding. However, the extent of obesity, and family histories of CAD could account for the significant deviation from the STS in regard to triple vessel disease and history of myocardial infarction.

The relatively recent initiation of this cardiac surgery program and its rural catchment area may account for the distribution of cases (fewer elective and redo surgeries, but more emergent cases) because: (1) the cardiac surgery program was actually put into place to support interventional cardiology, (2) the cadre of cardiologists was not as well established at this location and had fewer elective cases posted, (3) the proximity to several rural hospitals allowed rural emergent cases (whether initially presenting to the study site emergently or becoming emergent during their rural hospital stay) to receive expeditious care, (4) the surgeons did not have an office in the immediate area and this affected their contribution of elective cases to the institution, and (5) a newly established program would have less opportunity to perform redo surgeries.

The surgeons at the study location were very experienced and were strong advocates of mammary and radial artery use [32], and this is reflected in their shorter aortic cross-clamp (perfusion) times and their use of internal mammary grafts as compared to the STS. However, the surgical group was less enthusiastic for the use of off-pump coronary artery bypass procedures. The increased use of intra-aortic balloon pumps and blood transfusions in our population may be attributed to the increased severity of

95% C.I = 95% confidence interval; CPB = cardiopulmonary bypass;
Predictors are arranged by decreasing Wald statistic

illness as represented by an increased percentage of emergent cases, preoperative myocardial infarctions, and triple vessel disease.

The postoperative complications of renal dysfunction (no dialysis), prolonged ventilation greater than 24 hours, leg wound infection, atrial fibrillation, and 30-day readmission deviated from the STS. Postoperative renal dysfunction was not associated with an increased need for dialysis. The higher rate of renal dysfunction may be linked to a higher incidence of emergent cases done soon after cardiac catheterization. Such prompt surgeon response may not allow sufficient time for elimination of the contrast dye that may exacerbate the associated nephropathy [33].

Postoperative atrial fibrillation in our population is greater than the STS, but is within the range reported by others [34,35]. This may be related to the greater incidence of emergent cases and shorter catheterization-to-surgery times. The latter may have compromised the efficacy our implementation of the amiodarone prophylaxis protocol in high-risk atrial fibrillation patients.

The prolonged rate of postoperative ventilation may be a function of anesthesiology practice. In the evening the cardiothoracic anesthesiologist covers the intensive care unit by beeper. Although protocols are in place regarding extubation and the anesthesiologist can be consulted at any hour, we have found that there is reluctance to extubate patients between midnight and 0600 on the part of the staff. However, this did not influence the length of stay or the rate of pneumonia.

The cardiovascular surgical assistants hired at the study location initially had limited experience with the surgical care of leg wounds. Their ability to care intra-operatively and post-operatively for leg wounds has improved and is under a continuous quality improvement process. The extent of obesity and emergent cases in our population may be a contributing factors to poor wound healing. Also, the emergent cases arrive in the operating room on many occasions after administration of antiplatelet drugs and this may contribute to postoperative hematoma formation and infection at the leg wound sites.

An increased 30-day readmission rate of the study site was also noted. The surgeons initiating this cardiac surgery program had heightened awareness as to potential patient complications in a "new" program and did not hesitate to readmit a patient of questionable physiologic status.

In our paradigm a group of high volume surgeons from a high volume hospital (HVH) established a new LVH cardiothoracic surgery program providing practice guidelines, protocols and data acquisition capabilities. In addition, the physical layout of the cardiac surgery wing and the organization of the cardiovascular intensive care unit (CVU) within a dedicated heart center were of paramount importance. It included two cardiac catheterization suites with a 10 bed holding area, two operating suites were immediately adjacent to an eight-bed CVU used as intensive care, step-down and floor beds if capacity permitted ("one-stop" for all patients). An experienced critical care nursing staff was recruited from the HVH. In addition, two anesthesiologists/intensivists with transesophageal echocardiography skills were dedicated exclusively to the heart center. They were responsible for the pre-, intra-, and postoperative critical care of all the patients. The CVU model was one that involved the cardiac surgeon as the primary physician; however the anesthesiologists were consulted on every case to support the global care given to the patient. This was particularly beneficial to the surgeons because their practice involved three institutions in addition to their office practice. Also, daily group rounds included a surgeon, anesthesiologist,

0403
09/15/08

nurse, respiratory therapist, and pharmacist. Each month a meeting was held, not only for case review, but to assess the program's performance against the STS database.

Clearly, surgeon procedure-volume examination will cause controversy [36-38], but studies of risk-adjusted data indicate that surgeon volume is of significant importance [13,14,16,17]. In the setting of a LVH where there are more emergent and high risk patients [14] there should be a continuous quality improvement effort in place to ensure "best practice", evidence-based care is offered to patients [12].

Conclusion

We demonstrated that high quality CABG care with good outcomes can be achieved at a LVH program provided that that it is served by high volume cardiac surgeons and backed up by a highly trained, dedicated support team, and a sophisticated data acquisition capability and review process. This approach may prove a useful paradigm to ensure high quality CABG care and early efficacy at low volume institutions that wish to be compliant with Leapfrog recommendations.

N Kalant, I Shrier. Volume and outcome of coronary artery bypass graft surgery: Are more and less the same? Can J Cardiol 2004;20(1):81-86.

BACKGROUND: Despite the relatively high degree of regionalization of coronary artery bypass graft surgery in Canada, support is expressed for even further centralization of this procedure. The finding that the risk-adjusted mortality rate is lower at high volume hospitals is the basis for the decision to centralize. The goal of this study was to determine if current evidence supports the extension of such a policy.

METHODS: A systematic review of the literature (1980 to 2002) provided mortality and surgical volume studies on 21 patient cohorts. For 16 of these, the published information permitted division of each cohort into those who had surgery at high or low volume hospitals. The target level for division was 200 cases per year; the level achieved was 200±44 (mean±SD). The odds ratio (OR) was calculated from the observed and expected mortality ratios. In seven studies, volume had been treated as a continuous variable; the effect of volume was expressed as OR per 100 patients in four of these studies.

RESULTS: A plot of OR against year of surgery showed a progressive increase from 0.55 (favouring high volume) in 1972 to 0.95±0.07 for the past few years. All estimates of OR per 100 patients were very close to 1.0, also indicating little or no effect of volume on mortality.

INTERPRETATION: These results are compatible with the concept that with time the lower mortality associated with high volume has been virtually eliminated. It is hypothesized that this development is explained by a multifaceted learning curve, improved surgical training and technical advances. Therefore, the current evidence does not provide a basis for further regionalization of cardiac bypass surgery

Key Words: *Coronary artery bypass graft; Perioperative mortality; Regionalization; Volume of surgery*

Le volume et l'issue d'un pontage aortocoronarien : Plus ou moins donnent-ils le même résultat ?

HISTORIQUE : Malgré une régionalisation relativement élevée des pontages aortocoronariens au Canada, une centralisation encore plus marquée de l'intervention est proposée. L'observation selon laquelle le taux de mortalité rajusté au risque est plus faible dans les hôpitaux à fort volume justifie cette recommandation. La présente étude vise à déterminer si les données probantes actuelles soutiennent l'élargissement de la politique.

MÉTHODOLOGIE : Une analyse systématique de la documentation scientifique (entre 1980 et 2002) a permis de colliger des études sur la mortalité et le volume d'opérations dans 21 cohortes de patients. Dans 16 d'entre elles, l'information publiée a permis de diviser chaque cohorte en ceux qui ont été opérés dans des hôpitaux à fort et à faible volume. Le taux cible de division était de 200 cas par année. Le taux obtenu était de 200±44 (moyenne±ÉT). Le risque relatif (RR) était calculé d'après les risques de mortalité observés et prévus. Dans sept études, le volume avait été traité comme une variable continue. Dans le cadre de quatre de ces études, l'effet du volume était exprimé à titre de RR pour 100 patients.

RÉSULTATS : Le schéma du RR par rapport à l'année de l'opération indiquait une augmentation progressive de 0,55 (en faveur d'un volume élevé) en 1972 à 0,95±0,07 au cours des quelques dernières années. Toutes les évaluations du RR pour 100 patients se rapprochaient énormément du 1,0, ce qui indiquait également un effet minime sinon inexistant du volume sur la mortalité.

INTERPRÉTATION : Ces résultats sont compatibles avec le concept selon lequel au fil du temps, le taux de mortalité moins élevé associé aux hôpitaux à fort volume est virtuellement éliminé. Il est allégué que cette évolution s'explique par une courbe d'apprentissage polyvalente, une amélioration de la formation chirurgicale et les progrès techniques. Par conséquent, les données probantes actuelles n'étayent pas la régionalisation supplémentaire des pontages aortocoronariens.

In 1979, Luft et al (1) published a seminal article showing that hospitals performing a large number of certain operations had lower perioperative death rates than those conducting a smaller number. Subsequent studies confirmed this observation, but over time the results became more variable. Although the presence of such a relationship is subject to several interpretations (2), the most obvious is that at high volume hospitals, the personnel gain experience and become adept more rapidly than at low volume institutions (3,4). The improvement is thus seen as a manifestation of the learning process. It has been proposed that fewer lives would be lost during surgery and that society as a whole would benefit by concentrating the procedures that show such a volume-outcome relationship, at high volume hospitals, through selective referral or regionalization (4,5). In 1978, McGregor and Pelletier (5) calculated that both operative mortality and cost of coronary artery bypass graft (CABG) surgery would fall as the volume increased to 50 per year, but that there would be no benefit obtained from further increases. These concerns have been extended to individual surgeons, because restriction of the procedure to high volume surgeons might further improve the overall results (6). A recent report on the state of health care in Canada specifically emphasized the desirability of further regionalization of CABG surgery (7), and it was stated publicly that having too many centres undertaking heart surgery may result in unnecessary complications and deaths (8).

On the other hand, in a review of papers published from 1979 to 1992, Sowden et al (9) found that although initially the mortality rate was greater at low volume hospitals, during that interval the increasing thoroughness of adjustment for case mix and surgical improvements with time appeared to diminish the volume effect. Because of the policy implications for hospitals and surgeons, it is important to be certain that the volume-outcome relationship still holds, and that the causal explanation is correct. One of the factors that complicates decision making is the generalization from one or several surgical procedures to 'surgery' or from myocardial infarction to 'health care' (10). The objective of the present work is to determine if the current literature supports a policy of further extension of regionalization; it is confined to CABG surgery.

METHODS

Selection of papers for review

The Medline, HealthSTAR and Cochrane Collaboration databases were searched (January 1, 1980 to October 1, 2002) for English-language articles concerned with the quantitation of the relationship between the volume of surgery (hospital and/or surgeon) and the perioperative mortality for CABG surgery. Combinations of the following key words were used: CABG, bypass or by-pass, coronary, hospital volume, surgeon volume, high volume, low volume, mortality or postoperative mortality, death. Interpreting the search goal broadly, all articles of potential interest (including reviews) were retained. Each author independently reviewed the full text form of the retrieved articles and transcribed the required data onto a standardized form: year(s) in which patient cohort underwent surgery, source of patients, CABG volume at individual hospitals or the range of volumes in the groups of hospitals defined by the author(s), number and CABG volume of surgeons, and criteria used for case mix adjustment. Actual (observed), expected and adjusted mortality rates were recorded when available. The outcome of interest was perioperative death rates, expressed as odds ratio (OR) or as the regression coefficient of mortality on volume and other independent variables. The references of each article were scanned and those that appeared relevant were added to the initial list. Several review articles were of particular interest (9,11-14). Finally, the Science Citation Index was searched for papers that cited the key articles retrieved by other search methods. Disagreements concerning data entries or acceptability for inclusion in the review were resolved by consensus.

Analysis

The studies were separated into two groups, depending on whether volume had been treated as a dichotomous or a continuous variable in the regression analysis.

Volume as a dichotomous variable: The choice of volume at which to segregate high and low volume institutions is arbitrary; however, many authors have set the level at or near 200 cases per year. Using the same dividing point, the observed mortality rate/expected mortality rate (O/E) was calculated for seven patient cohorts from information provided; using these ratios, the OR was calculated for each volume group. The information was insufficient to permit such calculation in eight other cohorts: division into high and low volume hospitals had been made in the range of 100 cases per year to 230 cases per year in seven of these cohorts while in the eighth cohort, the high and low volumes were separated by a wide gap because the authors compared the five lowest volume with the five highest volume hospitals. The division into high and low volumes was not altered in these cases.

Volume as a continuous variable: The OR, obtained by exponentiation of the coefficient for volume (15), was taken from the original reports or calculated from available data. The OR calculated in this way referred to the probability of mortality when hospital volume was increased by a single additional patient (ie, it was the OR for [x+1]/x patients, where x was any number of patients at the low volume and x+1 was the number of patients at the high volume. To provide a more clinically relevant OR, the OR per 100 additional patients was reported:

$$OR=\exp^{(\text{coefficient}\times 100)}.$$

RESULTS

Studies selected

The selection process yielded studies of the mortality-volume relationship in 21 patient cohorts, aggregated to hospitals, to surgical teams or to both. Seven other studies were excluded for the following reasons:

a) Use of the same data set in several publications, as noted by Sowden et al (9), including cohorts from 1972 (1,16-18), 1986 (19,20) and 1989 (21,22). Only the most recent study from each of these groups was included.

b) Insufficient number of statistical units. Williams et al (23) examined the relationship of hospital volume to surgical mortality in five hospitals. They acknowledged that their failure to detect a correlation may have been due to the small number of hospitals.

c) Methodological problems. Nallamothu et al (24), in a novel approach, tested the hypothesis that the degree of benefit of a high hospital volume may be related to the level of risk facing the patient. After risk stratification of the patients and separation of hospitals into low volume (less than 200 patients per year) and high volume (greater than 200 per year) groups, the rates were lower at the high volume hospitals for the two risk strata 2% to 5% and 5% to 20%, but not for the stratum greater than 20%. Methodological questions place the significance of this work in doubt (25). (i) The risk strata into which patients were segregated were rather wide, particularly at the higher levels; thus one could not be certain that the mean and distribution of risk scores were the same in the two groups considered to be at the same level. (ii) The study population was confined to nonemergent patients and therefore was not representative of the whole CABG population. (iii) There was some doubt whether an analysis of variance should have preceded the series of χ^2 tests; if the F value was not significant then the multiple paired comparisons may not have been appropriate. This is especially important because the volume effect occurred in the moderate but not the high risk groups. For these reasons, the results were not included in the present review.

Some papers compared two or more patient populations that differed in location (26) or in year of surgery (22,27). These were considered independent cohorts and included as such in the analysis.

Analysis

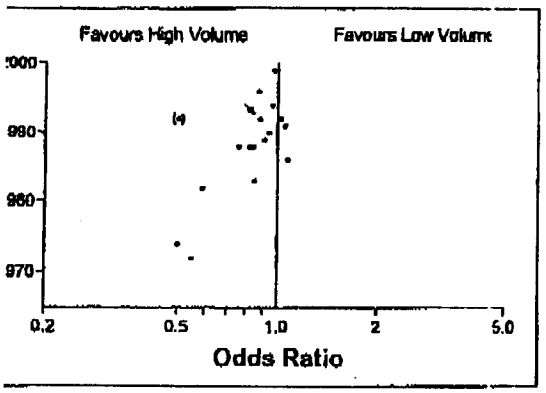

Table 1 shows studies based on multiple logistic regression with hospital volume as the categorical, independent variable

gure 1) Odds ratio for perioperative mortality following coronary tery bypass graft surgery, in high volume hospitals relative to low vol- ne hospitals. Each symbol represents a cohort of patients, with the ratio xted against the midpoint of the time interval during which members of e cohort underwent surgery. (•) is odds ratio of 1992 cohort (22) with u volume cutoff at 200 patients per year; these data are derived from o hospitals and 135 patients. →• indicates corresponding value for cut- at 225 patients per year, derived from three hospitals and 345 patients

id risk-adjusted mortality rate as the dependent variable of terest. The OR values corresponding to the regression analy- s show a continuous increase with time (Figure 1) and, for e past 10 years, a clustering about a value of 1.0, indicating at the risk-adjusted mortality was essentially equal at high and low volume hospitals. The value for the 1992 cohort (22) is an outlier; because it was derived from two hospitals with a combined patient population of 135, the estimate is very unstable. By placing the cutoff at 225, there are three hospitals with 345 patients in the low volume group, the estimate is more stable, and the result falls within the range of the other cohorts. In seven investigations of hospital volume-mortality relationships, volume was a continuous independent variable in the logistic regression (Table 2). In three studies in which logarithm of volume was used in place of volume in the regression, the coefficient of volume was negative, indicating a decrease in mortality rate as volume increased. There remain four estimates of OR per 100 patients for hospital volume-mortality relationship; all are very close to 1.0.

Three reports that did not have sufficient detail to permit inclusion in the analysis and are not presented in the tables nevertheless deserve comment. In two, presented as letters to the editor, the regression of risk-adjusted mortality on hospital volume deviated from linearity because of an increase in scatter of the data at low volumes (28,29). In both cases, the writers took these regression lines as evidence of a volume-mortality effect at low volumes. However, the increased scatter can be accommodated in a Poisson regression without assuming a volume-mortality relationship (30). The third (31) found an inverse relationship between hospital CABG volume and mortality rate ($P<0.02$) when risk adjustment was based only on age. After more extensive risk adjustment in a multivariate model, logistic regression showed no relationship and hospital CABG volume was not a predictor of mortality. Poisson regression did not reveal a volume relationship or evidence of a threshold for a volume effect.

Of five studies of the surgeon volume-mortality relationship in which the volume was considered a continuous variable, three gave an OR per 100 patients close to 1.0, one gave an OR against the hypothesis (ie, strongly favouring low surgeon volume), and one (volume expressed as the logarithm of volume) supported the hypothesis (ie, it favoured high volumes) (Table 3). Analysis of four cohorts, with volume as a categorical variable, gave OR values clearly favouring high volumes. There is no obvious explanation for these differences; thus, the results remain inconclusive for surgeon volume.

DISCUSSION

Despite continuing concern about the volume-outcome relationship in CABG surgery, some of the questions raised by the early work remain unanswered: Is there an inverse correlation between the volume of CABG surgery performed at a hospital and the quality of the outcome? If so, does volume decrease mortality or does low mortality attract more patients? Should the presence of such a correlation lead to a policy change designed to concentrate CABG surgery in a small number of high volume hospitals? Similar questions pertain to the volume of these procedures done by individual surgeons.

Is there a volume-outcome relationship? Two recent reviews have concluded that such a relationship does exist (6,32). Our results indicate that though a relationship was evident during the early years of CABG surgery, its magnitude diminished over time, virtually to zero. Comparison of these reviews with

0411
09/15/08

rs shows several important differences which may explain the ntrasting conclusions: (i) In both preceding works, CABG is ne of a variety of procedures studied; attention is focused on the lationship as a generalized phenomenon and on its policy plications rather than on its magnitude. (ii) Although pub-hed in 2000, the report of Dudley et al (6) includes no data m CABG performed after 1990 and thus neglects much relet int information. (iii) The conclusion of Halm et al (32) with gard to CABG is based on the median difference in mortality tween low and high volume hospitals. Of the eight publica-ns they analyzed, three did not provide such information on edetermined volume categories (31,33,34), and presumably re excluded from the median; because two of these (31,33) re the only ones that showed no dependence of outcome on lume, their omission may have biased the summary statistic. v) The major difference between the preceding reviews and e present one is in the role ascribed to time. Halm et al (32) ce both the time-related decrease in the difference between gh and low volume hospitals, and the absence of correlation tween outcome and short term fluctuation in volume at indi-lual hospitals (34); they interpret these observations as evi-nce of fixed differences in quality between high and low lume hospitals. Our results show the extension of improve-nt over time to the point of eliminating the difference tween high and low volume outcomes. This appears to be compatible with the concept of fixed differences.

ature of volume-outcome relationship: It is apparent that a cor-lation between volume and outcome may indicate (i) depend-ce of outcome on volume (improvement with practice),) dependence of volume on outcome (skill attracts more tients), (iii) correlation of both variables to a third factor ne use of CABG-specific, beneficial procedures in high vol-ne hospitals), or (iv) a combination of these. There is some direct evidence compatible with the improvement with actice hypothesis: Cromwell et al (35) found a 26.5% crease in operating time, associated with increasing volume, ring the first 12 years of hospital experience with CABG; e reduction occurred rapidly for the first few years, then pered off in a manner compatible with the traditional view of learning curve. It may reasonably be assumed that this con-buted to the overall decrease in operative mortality during e past 20 years (36,37). On the other hand, Luft et al (38) tained some evidence in support of the second alternative, t expressed doubt about the methodology used. Thus, the idence is weak for each of the two principal explanations for olume-outcome effect, and it is therefore surprising that sev-al observers base their recommendations on the implicit sumption that volume determines outcome (32,39).

If that assumption is made (explicitly), one can offer a rea-nable explanation of the temporal change in the effect of lume on outcome. We suggest that, during the early period CABG surgery, one would expect an individual hospital to ve a composite learning curve derived from individual sur-ons interacting with the curve of the hospital support staff; is would be reflected in a volume-mortality effect. As the sur-al technique spreads, a learning curve would be generated in w locations, with an increase in complexity of the combined rve. When diffusion of the technique was completed, as aining of new surgeons changed from learning by doing to rning under the direction of experienced surgeons in estab-hed programs, and as each hospital and surgical team ached its quality plateau, the volume effect would diminish in importance, becoming undetectable by present methods of assessment. The dichotomy of the results shown in Table 2 is explained by this hypothesis, because all the data supporting a volume effect were obtained before 1990.

Implications for policy: Two of the concepts that policy makers would apply routinely in an ideal world are: i) new policies governing medical practice, like medical practice itself, should be based on the best available evidence, so that decision-makers may be reasonably confident that implementation of a new policy will have the effect desired; ii) the implementation of a new policy should be accompanied by a planned evaluation of its effects, as advocated by proponents of continuous quality improvement (40). In the case of CABG, regionalization has been carried out in a number of jurisdictions, primarily to reduce costs; evidence to support this decision was provided by earlier studies of the volume-outcome relationship. Currently, there are calls for further regionalization; this raises two questions: i) The findings of Sowden et al (9), together with ours, suggests that the evolution of CABG surgery has reduced the importance of the earlier evidence. Individual studies may still show a small effect of volume on outcome but the overall pattern of results does not. Consequently, the combined evidence does not provide support for a policy of expanded regionalization. ii) It is possible that concentration in large centres has contributed to the improvement of outcome with time; however, there have been no prospective studies of planned regionalization, so there is no hard evidence of the benefits of the policy. On the contrary, it has been suggested by Houghton (12) that simply increasing the number of patients is very unlikely to improve the outcome of a hospital; it might be preferable to determine what it is that successful hospitals do differently from unsuccessful ones, and to implement these procedures in all hospitals (41). This has been accomplished by the techniques of continuous quality improvement (42).

The Cardiac Care Network of Ontario has recently decided to add three centres for cardiac surgery with the same volume criteria as those adopted in establishing the network: 500 cases per year per centre and 150 operations per year per surgeon. The results of the network are of the highest quality; however, because a number of factors may contribute to outcome, one cannot ascribe the Ontario results to the volume criteria. If the decision to add three (rather than four or five) centres is determined by the requirement for 500 cases per year, the planners may wish to reexamine this decision in the light of our results.

Limitations: There are two sources of error in the work described that are of potential concern. As with all such reviews, there is no certainty that all relevant articles have been found. That we independently found all the CABG related studies uncovered by Halm et al (32) and other recent papers is reassuring. The second concern is that of the statistical analysis. There have been criticisms of some of the statistical methods used in previous studies of the volume-outcome relationship: Goldstein and Spiegelhalter (43) and Grunkemeier et al (44) have noted that the error in the data is probably much greater than the analysts have allowed for; others have advocated the use of Poisson regression instead of multiple logistic regression (30), and of hierarchical methods in place of regression methods (45-47). Without access to the raw data, we could not test these ideas and therefore we accepted the statistical approaches of the original studies.

0412
09/15/08

Summary: We have extended the finding of Sowden et al (9) that the strength of the relationship between volume of CABG surgery and adjusted mortality rate has decreased over the past two to three decades, so that for surgery performed now there does not appear to be a measurable advantage to a high volume. Consequently, the current situation does not provide a basis for extension of the regionalization which has already been engineered.

Procedural Volume as a Marker of Quality for CABG Surgery

Eric D. Peterson, MD, MPH; Laura P. Coombs, PhD; Elizabeth R. DeLong, PhD; Constance K. Haan, MD; T. Bruce Ferguson, MD

JAMA. 2004;291:195-201.

ABSTRACT

Context There have been recent calls for using hospital procedural volume as a quality indicator for coronary artery bypass graft (CABG) surgery, but further research into analysis and policy implication is needed before hospital procedural volume is accepted as a standard quality metric.

Objective To examine the contemporary association between hospital CABG procedure volume and outcome in a large national clinical database.

Design, Setting, and Participants Observational analysis of 267 089 isolated CABG procedures performed at 439 US hospitals participating in the Society of Thoracic Surgeons National Cardiac Database between January 1, 2000, and December 31, 2001.

Main Outcome Measure Association between hospital CABG procedural volume and all-cause mortality (in-hospital or 30-day, whichever was longer).

Results The median (interquartile range) annual hospital-isolated CABG volume was 253 (165- procedures, with 82% of centers performing fewer than 500 procedures per year. The overall op mortality was 2.66%. After adjusting for patient risk and clustering effects, rates of operative m decreased with increasing hospital CABG volume (0.07% for every 100 additional CABG procedu adjusted odds ratio [OR], 0.98; 95% confidence interval [CI], 0.96-0.99; P = .004). While the a between volume and outcome was statistically significant overall, this association was not obser patients younger than 65 years or in those at low operative risk and was confounded by surgeor The ability of hospital volume to discriminate those centers with significantly better or worse mo limited due to the wide variability in risk-adjusted mortality among hospitals with similar volume of up to 100 of the lowest-volume centers (ie, those performing ≤150 CABG procedures/year) w estimated to avert fewer than 50 of 7110 (<1% of total) CABG-related deaths.

Conclusion In contemporary practice, hospital procedural volume is only modestly associated outcomes and therefore may not be an adequate quality metric for CABG surgery.

The association between hospitals' coronary artery bypass graft (CABG) surgery volume and outcome has been the subject of multiple investigations.[1-17] Based on these studies, the Center for Medicare & Medicaid Services (CMS) and the Leapfrog Group have proposed using hospital volume as an indicator of CABG quality.[18-20] Prior studies of the association between volume and outcome, however, generally have been based on administrative data sources, have reflected selected patient populations, and often have not adequately accounted for patient case mix, patient clustering, a methodological concerns. Before hospital surgery volume is accepted as a standard quality metr research into issues related to both analysis and policy implication is warranted.

We undertook a contemporary examination of the association between hospital CABG procedura and outcome using clinical data available from the Society of Thoracic Surgeons (STS) National (Database. Specifically, we considered whether hospital CABG volume was associated with opera mortality after accounting for patient case mix. Second, we examined the extent to which patien clustering within centers and site variance issues affected this association. Third, we determined association varied as a function of patient age and predicted surgical risk. Fourth, we determinec the association between hospital volume and outcome was influenced by individual surgeon volu Finally, we investigated the potential health policy implications of using hospital volume as a qua indicator. This included determining the ability of hospital volume to discriminate high-mortality as well as investigating the potential number of lives saved if low-volume centers were systemat closed.

Data Source

The STS National Cardiac Database was established in 1989 to report surgical outcomes following cardiothoracic surgical procedures.[21-23] The database currently captures clinical information from nearly two thirds of all US bypass procedures from more than half of all centers performing adult cardiac surgery. Sites enter patient data using uniform definitions (available online at http://www.sts.org) and certified software systems. This information is sent semiannually to the STS Data Warehouse an Center at the Duke Clinical Research Institute. There, a series of data quality checks are perform a site's data are aggregated into the national sample. While participation in the STS database is data completeness is high, with overall preoperative risk factors missing in fewer than 5% of sul cases.[24] The accuracy of submitted data has further been confirmed in independent comparison CABG surgery volume and mortality rates reported to the STS vs those reported to the CMS.[24]

Patient Population

We examined isolated CABG surgery procedures, excluding those combined with valve or other surgical interventions, performed between January 1, 2000, and December 31, 2001, at hospita reporting to the STS. We excluded 12 centers (2.7% of total STS centers) that reported fewer th CABG procedures in a year and that had evidence for incomplete reporting. Inclusion of the 223 from these 12 centers had no measurable impact on the study's measured association between procedural volume and outcome.

Statistical Analysis

Our primary outcome measure was all-cause operative mortality, defined as in-hospital or 30-da mortality, whichever was longer. Major morbidity was defined as any of 5 postoperative in-hospi complications: stroke, reoperation for any reason, need for mechanical ventilation for more thar following surgery, renal failure, or deep sternal wound infection.[25]

Hospital-isolated CABG annual case volume was averaged over a 2-year period (2000 and 2001) increase its stability. In the overall analysis, volume was considered to be a continuous variable. display purposes, patient and hospital characteristics and unadjusted outcomes were categorize annual hospital procedural volume (≤150, 151 to 300, 301 to 450, and >450). These break poin chosen to form 4 fairly equal-sized hospital samples while maintaining similar volume difference the groups.

The effect of hospital volume on unadjusted outcomes was tested using standard logistic regres Expected mortality rates for patients were calculated using a logistic regression model that inclu previously identified preoperative risk factors[25] and year of surgery. The C-index for this model study population was 0.78. Risk-adjusted mortality rates for each hospital were calculated by di observed mortality rate by the expected mortality rate at the hospital and multiplying by the ove (national) bypass mortality rate. Additionally, hierarchical logistic regression was used to accour patient clustering within centers (SAS Macro GLIMMIX).[26] These analyses included clinical risk fa procedure year, and hospital procedural volume as a fixed effect and included random intercept To supplement this analysis, a hospital-level weighted least-squares regression of risk-adjusted on volume was used to correct for nonconstant variance associated with hospital sample size, as by hospital volume.[27] This method assigned greater weight to observations with smaller varianc

Because many previous studies have focused on Medicare populations (ie, those with patients a years) while others have specifically investigated the effect of hospital volume as a function of p risk,[13, 15] we also tested for interactions between hospital volume and patient age (<65 years ar years) and expected risk for patients in our hierarchical analyses. We also used our hierarchical test the hospital volume x surgeon volume interaction. While the STS database does not contain names of individual surgeons, it does contain an encrypted primary surgeon identifier that can b aggregated within and among hospital locations to approximate annual surgeon volume.

Finally, we also examined health policy implications of hospital volume. We first determined the which hospital volume identified "mortality outlier" hospitals as determined by their significance hierarchical logistic regression model containing patient characteristics but not volume. Specifica used a hospital-level standard logistic regression model to test whether hospital procedural volu discriminate mortality outliers. Second, we assessed the potential number of lives saved from cl either the lowest hospital volume quartile in the STS database (≤150 CABG procedures per year) alternatively using the Leapfrog-proposed referral criteria of fewer than 500 procedures per yea these calculations, we assumed that all these patients could safely be transferred from low- to h volume centers without risk and that the patients would assume the expected risk predicted for higher-volume site once there. All statistical analyses were performed using SAS release 8.2 (SA Institute Inc, Cary, NC), with $P<.05$ considered statistically significant.

439 STS hospitals. Average hospital procedural volumes ranged from 39 to 1754 isolated CABG procedures (median, 253; interquartile range, 165-417). Eighteen percent of STS centers performed 500 or more procedures per year.

Table 1 displays patient and hospital characteristics as a function of hospital volume. Compared with higher-volume centers, lowest-volume hospitals (ie, those performing ≤ procedures per year [n = 98]) were more likely to operate on nonwhite patients, as well as on p with chronic lung disease, prior stroke, recent myocardial infarction, left main artery disease, an emergent or salvage settings. Based on preoperative risk factors, the average expected surgical risk ranged from 3.0% for hospitals performing 150 cases or fewer to 2.6% for those performinç than 450 cases. The Pacific and West South Central regions tended to have more low-volume hc region, while New England, and the Mid-Atlantic, South Atlantic, and East South Central regions high-volume centers.

Table 1. Patient and Hospital Characteristics*

Hospital Volume and Outcomes

Overall, there were 7110 deaths (2.66%). Overall unadjusted mortality declined from 3.5% for l in the lowest-volume group to 2.4% for hospitals in the highest-volume group ($P<.001$ for trend 2). Rates of prolonged ventilation and renal failure also declined significantly ($P<.001$ for both) \ increasing hospital procedural volume. Reoperation, stroke, and rates of deep sternal wound infe were generally constant across volume group, as was postoperative length of stay (median, 5 da volume groups).

View this table:

[in a new window]

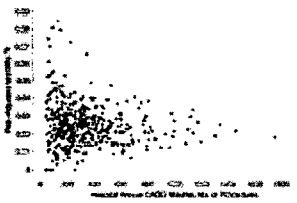

Table 2. Unadjusted Outcomes

After adjusting for preoperative clinical risk, year of surgery, and patient clustering within centei mortality declined significantly as a function of hospital procedural volume, ranging from 3.1% fe performing 150 or fewer cases per year to 2.4% for those performing more than 450 cases per \ When looking at hospital volume as a continuous variable, absolute rates of mortality decreased for every 100 additional CABG cases per year (adjusted odds ratio [OR], 0.98; 95% confidence i [CI], 0.96-0.99; $P = .004$).

Although the relationship between hospital procedural volume and risk-adjusted mortality was s significant, there was wide variance in results observed among individual centers, particularly in volume category (Figure 1). While part of this variance is inherent, due to sample-size effects, tl association between hospital volume and outcome persisted after correcting for nonconstant var among sites by means of weighted least squares ($P = .001$).

Procedural Volume

Each dot represents a hospital reporting data to the Socie Thoracic Surgeons National Cardiac Database. CABG indi coronary artery bypass graft.

Effect of Volume on Outcome in Patient Subgroups

The absolute effect of hospital volume was more apparent in elderly patients (Figure 2). In patie 65 years and older, there was a 1.0% difference in observed mortality rates between low- (≤150 high-volume (>450) hospitals that was only slightly diminished after adjustment for risk (P<.00 contrast, among those younger than 65 years, observed mortality declined by only 0.3% and wa insignificant after adjustment for risk (P = .53).

Table 4. Risk-Adjusted Mortality, by Hospital and Surgeon Volume*

Policy Implications

The use of hospital procedural volume was of limited value in discriminating those hospitals with significantly better or worse risk-adjusted mortality outcomes ("outlier centers") (C-index, 0.60 respectively). In fact, as procedural volume dropped, a hospital's likelihood of being singled out center with significantly better or worse outcomes declined due to increasing variance associated measurement of end point at low-volume sites.

An upper boundary for the potential numbers of lives saved by closure of low-volume CABG cent also estimated. If 25% of STS hospitals with the lowest annual CABG volume (≤150 procedures) closed and their patients undergoing CABG surgery were safely transferred to another, higher-v center, then approximately 45 CABG procedural deaths could be averted annually among all 43S centers. If the criteria for selective referral were based on Leapfrog's referral criteria of 500 case year,[18] 82% of STS centers would close and the high-end estimate of avertable CABG deaths wc 212 per year.

Validity of STS Data

In order to determine the validity of STS data for patients aged 65 years and older, we performe systematic comparison with data supplied to the CMS. There were 415 centers that released dat STS and the CMS; more cases (96 330 vs 78 788) were reported to the STS, likely due to nonre health maintenance organization and managed care cases to the CMS. The reported mortality ra 4.50% and 4.48%, respectively. Reported mortality rates among centers that performed 150 or procedures per year were 5.06% and 4.91% according to the STS and the CMS, respectively, wl corresponding rates for centers that performed more than 150 cases per year were 4.39% and 4 Thus, we doubt that our results were biased by underreporting or selective reporting to the STS.

We also systematically compared mortality rates among participants and nonparticipants in the Mortality rates in participating sites were lower (4.5% vs 5.2%), but the differential mortality be lower-volume sites (≤150 CABG procedures/year) and higher-volume sites (≥151 CABG procedu was larger in the STS sites than in nonparticipating sites (0.6% vs 0.1%, respectively). Thus, th association between volume and outcome may have been overestimated by focusing on STS site

The recent interest in using hospital procedure volume as a quality indicator for CABG surgery is understandable. This structural characteristic is readily available via administrative claims data, requires no complex adjustment techniques, is easily interpretable by the lay public, and is consistent with the common belief that "practice makes perfect."[20] However, our study indicates that hospital volume has only a modest association with risk-adjusted mortality and has important limitations as a quality metric for CABG surgery.

To date, there have been multiple analyses of volume and outcome for CABG surgery. Most[1-15] l all[16-17] of these concluded that hospital procedural volume was associated with lower rates of hc

0419
09/15/08

mortality. The largest analysis of the association between volume and outcome was conducted b Birkmeyer et al.[14] Using national Medicare claims data from 1994 to 1999, they found a 1.3% al difference in unadjusted rates of mortality between the lowest to highest quartiles of hospital vo While their study was geographically inclusive, it was limited to patients aged 65 years or older, adequately adjust data for potential differences in case mix, and did not control for patient clust within sites or for site variance issues.

One of the most complete evaluations of CABG volume-outcome relationships performed using c data was completed by Hannan et al.[9] Using data from 30 centers performing CABG surgery in N from 1997 to 1999, the study by Hannan et al also noted significant differences in risk-adjusted among low- and high-volume hospitals. The study, however, was limited to a single state where certificate-of-need program limits the number of low-volume centers (ie, <3% of all patients rec surgery at centers performing <300 procedures per year).

Our contemporary analysis using clinical data from the STS National Cardiac Database found an association between procedural volume and unadjusted mortality similar to that found in past ar Our study, however, expanded on these prior analyses using contemporary analytic techniques t account for clinical factors, differences in site variability, and clustering within sites. We found th compared with high-volume hospitals, low-volume hospitals tended to operate on patients with l and under more emergent conditions (Table 1). Reasons for these differences may include adver selection,[7, 10] variance in clinical coding among hospitals, or a differential threshold for surgery c altered center experience and/or institutional financial pressure.

We also found that the association between hospital volume and mortality was not constant amc patients. In particular, the volume-outcome effect was nonsignificant in patients younger than 6 and in those with low preoperative risk (Figure 2, Table 3). These results imply that prior analys performed exclusively in Medicare patients would inflate the volume-outcome effect. Additionally presumed that while young, low-risk patients would be the group most likely to use public inforr from CABG quality metrics, these are also the patients in whom hospital volume had no measur association with outcome.

We further demonstrated that associations between hospital volume and outcome were confoun concomitant effects of surgeon volume (Table 4). These results expand those previously reporte single state[9] to a national cohort. Even if a patient elected to receive surgery at a high-volume c their risk-adjusted mortality rates could vary from 2.4% to as much as 2.9%, depending on whe not their actual procedure was performed by a low- vs a high-volume surgeon.

Our study further demonstrates the limitations of using hospital volume as an indicator of the qu CABG surgery. Hospital volume had generally poor predictive accuracy as a means of identifying with significantly better or worse CABG mortality rates (C-index, <0.7). Similarly, using volume referral criterion for selecting a provider would unfairly defer cases from nearly half of very-low- centers with outcomes equal or better than overall STS mortality results (Figure 1).

Regardless of its value at the level of the individual center, some still have argued for using hos volume limits for their "aggregate societal good." A study from California estimated that up to 2 deaths at low-volume centers may be averted with selective referral.[29] In contrast, our study es that the total number of lives saved by eliminating up to 100 low-volume STS hospitals (25% of sites) would be less than 1% from deaths (n = 45). If Leapfrog-proposed referral criteria of 500 cases per year were applied, up to four fifths of STS sites would be closed while fewer than 3% STS CABG mortality events would potentially be averted.

0420
09/15/08

This study does not fully preclude the use of procedural volume in certain roles. In particular, th but consistent association between hospital procedural volume and outcomes should be consider prospectively determining the need for new programs.[30] Additionally, given that quality assessm on comparison of risk-adjusted outcomes is limited at low-volume sites due to wide 95% CIs sur their outcome estimates, it seems reasonable to monitor low-volume centers using trend analys multiyear adjusted outcomes to ensure quality of care.

Several limitations should be noted. While this study represents the largest clinical evaluation of volume to date, the STS National Cardiac Database currently collects data from roughly half of a surgical centers. Participating centers tend to be larger and have slightly better outcomes than nonparticipating centers. However, unadjusted results in this study were similar to those from pr studies. Our evaluation of surgeon volume was limited to a blinded proxy and may underestimat impact. Third, while our study indicated that low-volume centers may have been more willing to on higher-risk patients, it could not determine whether this lower threshold for case selection wa indicative of better or worse patient care. Further study of the appropriateness of case selection hospital volume would be indicated. Finally, our study was not designed to isolate specific clinica mechanisms for the association between volume and outcome. Differences in surgical teams, qu postoperative care, surgical techniques, and other unmeasured factors all may contribute to the observed in this study.

In this national study we found that hospital procedural volume was only modestly associated w adjusted CABG mortality rates; however, there were many low-volume hospitals with low morta and some high-volume centers with rates higher than expected. This study suggests that hospit surgery volume is best considered as a surrogate for quality in a setting where other more direct and outcome assessments are not available.[20] Instead it seems more reasonable to support the growth of national clinical databases, which are capable not only of tracking risk-adjusted surgic patterns and outcomes, but also of improving them.[23, 31]

Statistical expertise: Peterson, Coombs, DeLong.

Obtained funding: Peterson, Ferguson.

Administrative, technical, or material support: Ferguson.

Study supervision: Peterson.

Role of the Sponsor: This study was sponsored by the Society of Thoracic Surgeons (STS). Sp the Duke Clinical Research Institute (DCRI) has a contract with the STS to be their National Carc Warehouse and Analysis Center (Dr Peterson, principal investigator of this subcontract). In this i DCRI independently harvests data from each participating STS center, creates a national analysi database, and performs statistical analyses. The proposal for this study was submitted by Dr Pet the STS national database publications committee (a 6-member board representing both the ST DCRI). After approval, the manuscript was reviewed by the coauthors and a final version approv publications committee.

Author Affiliations: Outcomes Research and Assessment Group, Duke Clinical Research Institu Durham, NC (Drs Peterson, Coombs, and DeLong); University of Florida Health Science Center, Jacksonville (Dr Haan); LSU Health Sciences Center, New Orleans, La (Dr Ferguson).

6. CORONARY HEART DISEASE

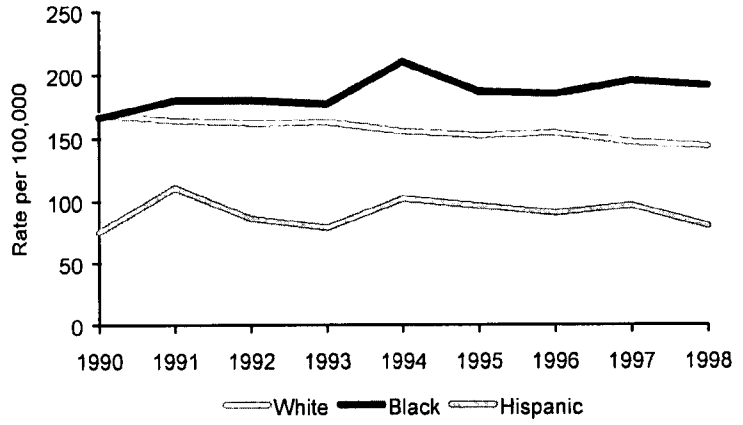
INTRODUCTION

Cardiovascular disease (CVD) is the leading cause of death and hospitalization for women in Connecticut, accounting for 44 percent of all female deaths in the state. Contrary to the belief that it is a man's disease, approximately 1,000 more women than men die from CVD each year in Connecticut. Despite women's concerns about cancer, nearly twice as many Connecticut women die from CVD than from all cancers combined (21,000 vs. 11,000 for years 1996-1998) (Mueller et al., in preparation). It is estimated that 1 in 2 women will eventually die from CVD compared with 1 in 25 who will eventually die from breast cancer (American Heart Association, 1996).

Cardiovascular disease encompasses heart disease, cerebrovascular disease (stroke) (*Chapter 7*), and other circulatory system disorders (Fig. 6-1). Heart disease accounts for 76 percent of the CVD female deaths and 69 percent of the CVD female hospitalizations in Connecticut. Stroke accounts for 18 percent of CVD female deaths and 18 percent of the CVD female hospitalizations in Connecticut (Connecticut Department of Public Health, Division of Policy, Planning, and Analysis, 2001). Heart disease includes congenital and valvular disorders, cardiomyopathies, congestive heart failure, and coronary heart disease (CHD), the latter being the most common form of heart disease.

FIGURE 6-1
CARDIOVASCULAR DISEASE DEATHS
Connecticut Females, 1996-1998

Source: Mueller et al., in preparation.



SCOPE OF THE PROBLEM

Coronary heart disease includes acute myocardial infarction (heart attack), angina pectoris (chest pains), and other forms of ischemic heart disease that occur when the flow of blood to the heart is restricted. It is the leading cause of CVD death and hospitalization in Connecticut women. During the three-year period from 1996 to 1998, 10,826 women died from CHD. During 1997, there were 9,813 hospitalizations due to CHD for women, which translates to an age-adjusted rate of 481 per 100,000 females. Hospitalization charges during 1997 exceeded $172 million (Connecticut Department of Public Health, Division of Policy, Planning, and Analysis, 2001).

From 1989 to 1998, there has been a significant downward trend in Connecticut female CHD mortality rates (Fig. 6-2), accounted for by the decrease in CHD deaths among white women. At the same time, the CHD death rate among black women has remained relatively unchanged. This results in a greater disparity in the mortality rate between black and white women. (Fig. 6-2, Table 6-1). The CHD death rates of Asian and Pacific Islander and Hispanic women were significantly lower than that of white women from 1996 to 1998.

Although the low death rates among Asian and Pacific Islander and Hispanic women may be partly due to under-reporting of these groups on death certificates (Rosenberg, 1999), low Hispanic mortality has been consistently seen in national surveys, and is still largely unexplained (Abraido-Lanza, et al., 1999). Contrary to the disparate black and Hispanic CHD mortality rates, the CHD age-adjusted hospitalization rates from 1993 to 1997 for black, non-Hispanic women and Hispanic women (respectively 557 and 520 per 100,000) were both significantly higher than for white, non-Hispanic women (479 per 100,000).

RISK FACTORS

Factors that increase the risk of developing CHD, but which cannot be changed, include advancing age and having a family history of heart disease. Other factors associated with an increased CHD risk, but which may be modified by life-style changes and pharmacologic therapy, include hypertension (high blood pressure), hypercholesterolemia (elevated cholesterol), diabetes mellitus, smoking, physical inactivity, poor diet, and obesity. Table 6-2 shows the relative impact of CHD risk factors for women, as well as the percentage of Connecticut women who responded positively to risk factor survey questions from the 1999 Behavioral Risk Factor Surveillance System (BRFSS) survey (Centers for Disease Control and Prevention, 2000).

Lifestyle Factors

Cigarette smoking is a leading cause of CHD in women. Smoking damages the inner arterial wall, raises blood pressure, and promotes intravascular clotting (thrombosis). It is estimated that more than 50 percent of heart attacks among middle-aged women are attributable to cigarette use (Willett et al., 1987). Female smokers have an 80 percent increased risk of developing CHD as compared with female nonsmokers (Table 6-2). The prevalence of cigarette smoking in Connecticut women was 21 percent in the 1999 BRFSS survey

Dietary factors affect CHD risk. Trans fatty acids have been linked to adverse lipid profiles and increased risk of CHD (Willet et al., 1993). Diets low in saturated fat and high in fruits, vegetables, whole grains, and fiber are associated with a reduced risk of CHD (Willet, 1996). CHD risk is lower in those who drink alcohol moderately (an average of one drink for women per day) than in nondrinkers, but it may raise blood pressure (Fuchs et al., 1995).

Diets high in saturated fat combined with physical inactivity can lead to excess weight and obesity. In addition to being a risk factor for CHD, obesity increases the incidence of other risk factors such as elevated cholesterol levels, high triglyceride levels, and increased likelihood of hypertension and diabetes mellitus. Overweight women are 40 percent more likely to develop CHD than those who are not (Table 6-2). Based upon the 1999 BRFSS data, 27 percent of Connecticut women were considered to be overweight (defined as a body mass index > 27.3.[1]

[1] Body mass index is calculated as weight in kilograms divided by height in meters, squared.

Psychosocial factors such as work stress, depression, or loneliness may cause individuals to be at a higher risk of developing heart disease, but their role is not yet clearly defined. That is, psychosocial factors may be interrelated to other health-related behaviors such as smoking, diet, or physical activity, which in turn may increase the risk of coronary heart disease. On the other hand, these factors may be independent and cause direct physiological changes (Hemingway et al., 1999).

Contributing Factors

Hypertension, or high blood pressure, is associated with a 50 percent increase in CHD risk over women without the condition (Table 6-2). Studies indicate a strong association between high levels of both systolic and diastolic blood pressure and risk of CHD in women (Whelton et al., 1996). Of particular concern for women is isolated systolic hypertension which has been associated with a sixfold to tenfold risk of CHD death over 15 years (Bittner, 2000). According to the 1999 BRFSS data, 21 percent of Connecticut women reported ever having been told that they had high blood pressure (defined as >140mm Hg systolic and as >90mm Hg diastolic).

Elevated low density lipoprotein (LDL) cholesterol and low high-density lipoprotein (HDL) are risk factors for CHD in women. LDL is the form in which cholesterol is transported to cells for membrane and steroid synthesis. High-density lipoprotein (HDL) helps remove cholesterol from body tissues and transports it to the liver for excretion. A high total cholesterol level (> 240 mg/dL) is associated with a 10 percent increase in CHD risk over women without the condition (Table 6.2), but is a less informative measure since it includes both LDLc and HDLc, which have opposite effects. During 1999, 82 percent of Connecticut female BRFSS respondents reported ever having their cholesterol tested. Of these, 27 percent indicated that they had been told that their cholesterol level was high. Triglycerides are fatty compounds found in LDL and HDL. Their role in CHD risk is unclear, but observational studies suggest they may be a particularly important risk factor in women.

Diabetes mellitus is one of the most important sex-specific risk factors for CHD. It significantly increases CHD risk among women by amplifying the effect of other risk factors. It is associated with a threefold to sevenfold elevation in CHD risk among women compared to nondiabetic women, whereas diabetic men have only a twofold to threefold elevation in risk compared to nondiabetic men. This sex-based difference may be due in part to a more deleterious effect of diabetes on lipids and blood pressure in women (Manson, 1996). Diabetes seems to increase atherosclerosis by changing the chemical makeup of some of the substances found in the blood (see Chapter 16, *Diabetes*).

TABLE 6-2
CORONARY HEART DISEASE RISK FACTORS

Risk Factor	Relative Risk (95% CI)	% CT Women Reporting Presence of Risk Factor
Diabetes mellitus	2.4 (1.9, 3.0)	4
Smoking	1.8 (1.5, 2.1)	21
Hypertension	1.5 (1.3, 1.8)	21
Overweight	1.4 (1.2, 1.6)	27
High cholesterol level	1.1 (0.9, 1.2)	27

Note: CI = Confidence interval

PREVENTION

Prevention of CHD includes preventing the development of CHD, screening for existing risk factors, lifestyle modifications, or pharmacologic intervention. Recommendations include smoking cessation, weight management, increasing physical activity, incorporating a diet low in fat, reducing stress, and diagnosing and treating high blood pressure and high cholesterol levels. Adherence to a healthy lifestyle has been shown to reduce the risk of CHD in women by more than 80 percent (Stampfer, 2000).

Although elimination of smoking may not lead to reversal of atherosclerosis, it has been shown to reduce CHD risk close to that of women who have never smoked (Rich-Edwards et al., 1995).

A healthy diet that is low in fat and rich in fruits and vegetables has been shown to reduce the risk of heart disease by 7 percent to 9 percent. Such a diet works by reducing blood levels of homocysteine, an amino acid that has been linked to an increased risk of CHD (Appel et al., 2000). Dietary interventions, including salt-intake reduction, also play important roles in the reduction of hypertension.

Increased physical activity and loss of excess weight reduce CHD risk directly as well as indirectly. They are important in the control of other CHD risk factors such as hypertension, dyslipidemia (high LDLc, low HDLc), and diabetes. Hypertension and dyslipidemia can also be treated pharmacologically, thereby reducing CHD risk. Clinical trials indicate a 2 percent reduction in CHD rates for each 1 percent decrease in LDL cholesterol (Oberman, 2000).

Because of the increase in heart disease rates for postmenopausal women compared to premenopausal women, loss of estrogen as women age is thought to contribute to a higher risk of heart disease. Epidemiological studies have suggested that hormone replacement therapy (HRT) in postmenopausal women may afford protection from CHD. However, such effect may be confounded due to a "healthy woman selection bias" as documented by the Healthy Women's Study (Matthews et al., 1996). This study suggests that women who are wealthier and better educated (cardioprotective factors) are more likely to be prescribed HRT and to actually comply with the therapy, which may explain the protection attributed to HRT. Major clinical trials, such as the Women's Health Initiative, are currently underway to quantify the cardioprotective effect of HRT, but final results are not expected until 2006. The American Heart Association's most recent recommendation is *not* to initiate HRT for the sole purpose of primary coronary heart disease prevention, but to take into consideration the treatment's potential benefits and risks related to other diseases and conditions (Mosca et al., 2001).

While the use of HRT in primary prevention is still under investigation, the results of the Heart and Estrogen-progestin Replacement Study (HERS) do *not* support hormone replacement therapy for secondary prevention of CHD in postmenopausal women. Although the study showed an alteration in the lipid profile of postmenopausal women using HRT, there was no significant reduction in death or morbidity among women with established CHD. Therefore, women with existing CHD should not begin HRT, but those already receiving HRT may continue (Hully et al., 1998). The American Heart Association likewise advises against the prescription of HRT for the sole purpose of preventing heart attacks in women who already have CHD (Mosca et al., 2001).

Because of the long-term side effects of HRT, such as an increased risk of endometrial cancer and possibly breast cancer, pharmaceutical companies are developing selective estrogen receptor modulators (SERMs), often referred to as "designer estrogens," as an alternative. Without the negative effects to the breast and uterine tissues, these new drugs may help lower cholesterol and consequently the risk for CHD in postmenopausal women. With respect to CHD, SERMs have been shown to reduce levels of LDL cholesterol and the clotting protein fibrinogen, but to a lesser degree than HRT (Love et al., 1991; Walsh et al., 1998). Ongoing trials will determine the clinical impact of SERMs in women at risk for CHD (Barrett-Connor et al., 1998).

Secondary prevention refers to therapy to reduce mortality and recurrent CHD events in patients with established CHD. It is aimed at both control of risk factors and direct protection of coronary arteries from plaque development and eruption. Thus it involves many of the same factors as primary prevention.

In secondary prevention, aspirin therapy benefits women in both the acute and chronic phases of disease. Yet women are less likely than men to receive aspirin in the secondary prevention setting. Even after adjustment for age and other factors, there appears to be a systematic bias towards men receiving aspirin therapy more often than women. In addition to gender bias, women arriving at the emergency department with acute myocardial infarction may be at greater risk for delayed aspirin therapy because they tend to present with more atypical cardiac symptoms than men, such as neck, back, and jaw pain, nausea, and dizziness (Thoma et al., 2001).

Although beta-blocker therapy after myocardial infarction (heart attack) has been shown to decrease nonfatal myocardial infarction and sudden death by 20 to 30 percent regardless of the patient's sex, it tends to be underused (Yusuf et al., 1985). Clinical trials indicate that thrombolysis after acute myocardial infarction also reduces mortality rates among women and men, but women tend to have higher reinfarction rates than men (Bittner, 2000).

Use of diagnostic and therapeutic revascularization modalities may be related to sex differences in morbidity and mortality. Data from the Myocardial Infarction Triage and Intervention registry suggest that the gap in mortality between the sexes due to acute myocardial infarction is associated with a lower likelihood of women receiving CHD interventions. Women had twice the in-hospital mortality of men and were half as likely to undergo acute catheterization, angioplasty, or coronary bypass surgery (Kudenchuk et al., 1996). However, another study suggested that women were referred for bypass surgery at least as often as men when surgery offered the greatest survival benefits, while men were referred more often for surgery when it offered the least benefit relative to medical treatment (Bickell, 1992). From 1993 to 1997, a significantly higher proportion of Connecticut women hospitalized with AMI died than Connecticut men hospitalized with AMI (12% vs. 7%, respectively), and women were also significantly less likely to undergo percutaneous transluminal coronary angioplasty (15% vs. 21%) or coronary artery bypass graft operations (8% vs. 11%). Because the onset of CHD tends to occur later in women than in men, the older age of women may be a reason why fewer are referred for angioplasty or coronary artery bypass graft surgery. Results of surgery are usually poorer in older persons. Differences in procedure rates could also be due to differences in severity of coronary occlusion.

Cardiac rehabilitation after myocardial infarction reduces CHD risk. It includes exercise training, risk factor modification, and psychosocial and vocational counseling. Despite its benefits, women are less likely to enroll in these programs than men (7 percent vs. 13 percent) (Thomas et al., 1996).

In summary, there is compelling evidence that comprehensive risk factor interventions in women with CHD extend overall survival, improve quality of life, decrease or postpone the need for more invasive interventional procedures, and reduce the incidence of subsequent heart attacks. Therefore, women need to become more aware of heart disease, its risk factors, and its symptoms so that they can actively participate in risk reduction and disease prevention.

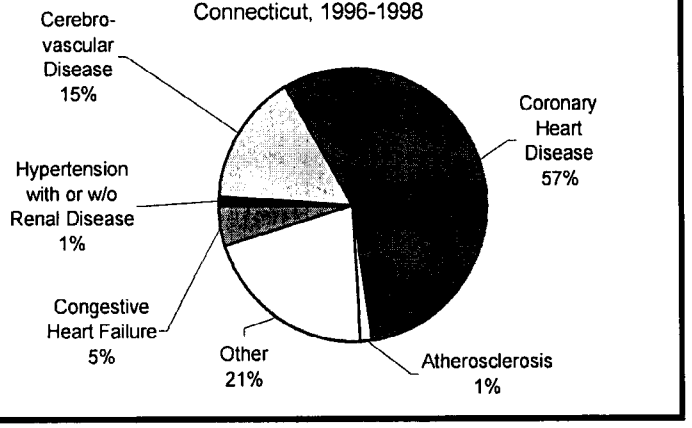
February, 2002

Cardiovascular Disease

Connecticut's Leading Killer

JOAN FOLAND, MHS, MPhil



CONNECTICUT DEPARTMENT OF PUBLIC HEALTH

Introduction

Cardiovascular disease is Connecticut's leading killer. Among both women and men, and across all racial and ethnic groups, cardiovascular disease is the state's leading cause of mortality. More than 12,000 residents die annually of CVD, accounting for 42 percent of all deaths.

Cardiovascular disease (CVD) refers to a variety of diseases and conditions affecting the heart and blood vessels. The major cardiovascular diseases are coronary heart disease (CHD), cerebrovascular disease, and congestive heart failure (CHF) (Fig. 1).

FIGURE 1
Cardiovascular Disease Deaths
Connecticut, 1996-1998

Coronary heart disease refers to any condition that reduces the flow of blood to the heart muscle. The blockage of blood flow can lead to chest pain (angina), irregular heart beats, or death of the heart muscle (heart attack). Cerebrovascular disease, more commonly referred to as stroke,[a] occurs when the blood supply to a part of the brain is interrupted. Congestive heart failure is a heart disease condition that involves loss of pumping ability by the heart, generally accompanied by fluid accumulation in organs like the lungs. It occurs when the heart becomes progressively weaker due to conditions such as high blood pressure or heart attack.

Chronic diseases like CVD are among the most prevalent, costly, and preventable of all health problems. CVD is the leading cause of death and hospitalization for Connecticut men and women in all age groups above 45 years. CVD is also the most expensive medical condition, accounting for one-seventh of health spending. The challenge is to control the social, economic, and medical burden arising from CVD, which, in turn, is driven by demographic, risk factor, and medical care trends.

[a] For purposes of discussion, cerebrovascular disease and stroke will be used interchangeably. Technically stroke is a subcategory, but it accounts for 86 percent of cerebrovascular disease deaths in Connecticut.

Health Burden

The number of deaths in Connecticut from all causes is approximately 30,000 per year, of which 12,000 (42 %) are due to CVD. In comparison, cancer, the second leading cause of death, accounts for 24 percent of all deaths. Seventy-eight percent of all deaths occur in people aged 65 and over, whereas 87 percent of CVD deaths occur in this age group. CVD not only affects the elderly; it is also the second leading cause of premature death under age 75. Although CVD is assumed to be a disease primarily of men, over half (55%) of all Connecticut deaths caused by CVD are among women.[b] According to the most recent National Center's for Health Statistics calculations, the probability at birth of eventually dying from cardiovascular disease is more than twice that of dying from cancer (47% vs. 22%).[1]

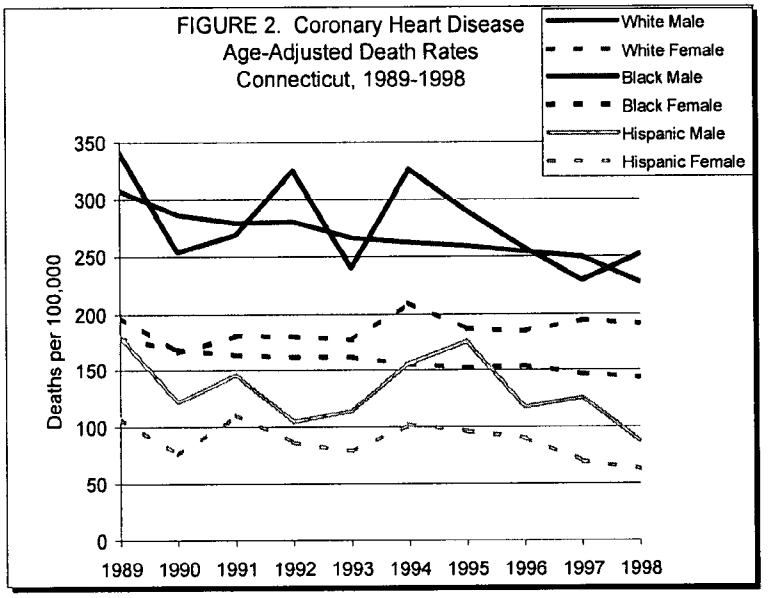
A consideration of deaths alone underestimates the burden of CVD. CVD is also the leading cause of hospitalization for the state's residents (excluding childbirth) and a leading cause of disability among working adults.[2] Approximately 61,500 resident hospitalizations annually are due to CVD, or approximately 23 percent of all hospitalizations, excluding newborns and pregnancy-related conditions.

Mortality

When considered separately among cardiovascular diseases, coronary heart disease ranks slightly below cancer as the leading cause of death in Connecticut (7,000 annual deaths), and cerebrovascular disease ranks as the third leading cause of death (2,000 annual deaths).

Age and sex differences in CVD mortality are well established. Mortality rates increase with age and males experience greater overall death rates and age-specific death rates than females (Table 1). These relationships also hold for coronary heart disease-specific death

[b] Although mortality rates are greater for males, the total number of CVD deaths is actually higher in females than in males, due to the average older age of death in women and the high mortality rates in the older age groups. This reinforces the fact that CVD is not just a problem for men.



rates. The risk of death due to CHD in females is roughly that of males ten years younger. It has been assumed that normal estrogen levels in pre-menopausal women provide a protective benefit against heart disease and possibly stroke, but recent research questions that reasoning.[3, 4] Sex-specific death rates due to cerebrovascular disease are not as disparate and are highest for females 85 years and older.

TABLE 1. MORTALITY RATES
Connecticut, 1996-1998

	Cardiovascular Disease Mortality Rates		Coronary Heart Disease Mortality Rates		Cerebrovascular Disease Mortality Rates	
Age Groups	Male	Female	Male	Female	Male	Female
< 45	16.3	8.3	7.9	2.4	2.0	1.7
45-54	149.7	60.9	103.0	28.5	9.4	11.1
55-64	455.4	201.2	297.3	114.7	44.2	23.9
65-74	1,130.6	622.5	711.4	334.8	120.7	97.6
75-84	2,995.7	2,058.2	1,768.9	1,076.9	428.7	396.1
85+	8,083.0	7,940.7	4,564.0	4,202.6	1,233.9	1,408.9
AAMR*	406.6	285.7	243.0	150.0	53.0	50.3
Total Deaths	16,747	20,586	10,077	10,826	2,132	3,654

* AAMR refers to age-adjusted mortality rate.

FIGURE 2. Coronary Heart Disease
Age-Adjusted Death Rates
Connecticut, 1989-1998

Cardiovascular disease death rates, particularly coronary heart disease rates, have been steadily declining over the past decade. Significant declines have occurred overall in both sexes, but primarily in those whose race is white (Fig. 2). The sex differences in mortality and time trends are likely due to differing lifestyle factors, such as smoking and diet. Improved medical and surgical care has also contributed to the changes.[5]

Although CHD mortality rates have decreased significantly for those whose race is white, rates among blacks and Hispanics have not statistically significantly changed since 1989; rather they have fluctuated with a large degree of variability. Because they have not changed over time, black female mortality rates are significantly greater than white female rates, which have declined (Fig. 2).[6] Black women are more likely to have certain CHD risk factors, such as being overweight or having hypertension or diabetes, and are less likely to receive particular treatments like bypass surgery.[7]

Low Hispanic mortality has been consistently seen in national studies and is still largely unexplained.[8] However, Hispanics tend to have fewer classic CHD risk factors when compared to white populations.[9] In Connecticut, significantly smaller percentages of Hispanics have reported having been told they have high blood pressure or high cholesterol levels than have white, non-Hispanics.[10]

Although stroke mortality rates have not significantly changed during the last decade in Connecticut, relative differences exist similar to CHD mortality rates between sexes and among race and ethnic groups (data not shown).

Unlike stroke, age-adjusted death rates for congestive heart failure have increased significantly from 1989 to 1998 (data not shown). Increasingly people are surviving heart attacks and preventing strokes, thereby increasing their risk for CHF.

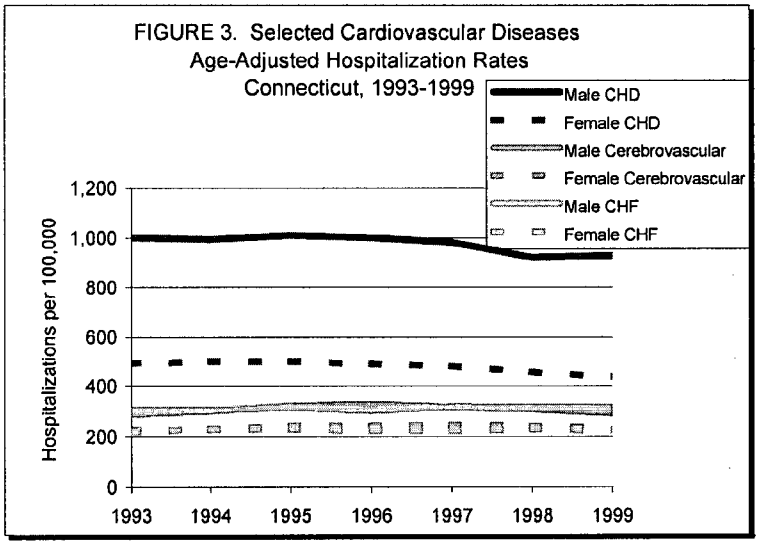
Morbidity

During 1999 there were approximately 61,500 discharges from Connecticut hospitals with some type of CVD as the first-listed diagnosis. They accounted for 23 percent of all discharges, excluding newborns and conditions relating to pregnancy and childbirth, making CVD the leading cause of hospitalization. Of these discharges, 23,300 (38%) were for patients with CHD, 9,400 (15%) were for patients with cerebrovascular disease, and 9,600 (16%) discharges had congestive heart failure (Table 2).

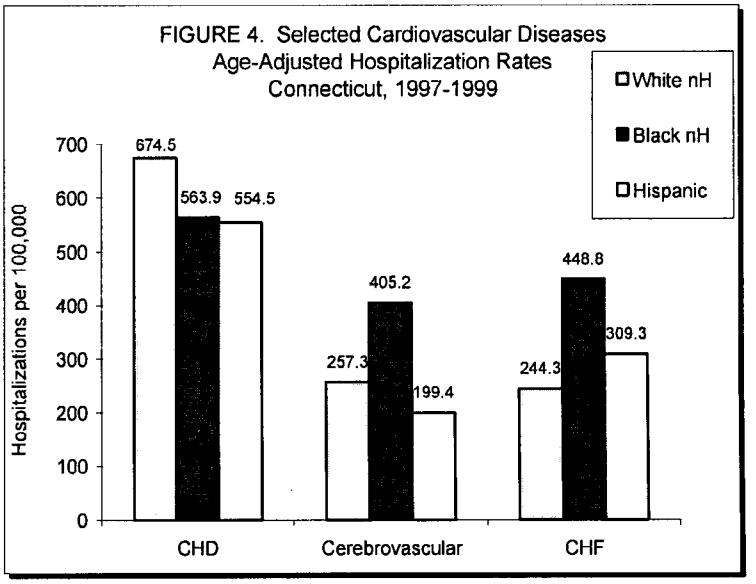
Sixty-two percent of CHD discharges were for people aged 65 years and over, whereas 78 percent of strokes and 82 percent of CHF discharges were in this age group. One third of CHD discharges occurred in patients aged 45-64, indicating that heart disease is not just a disease of the elderly. The median lengths of stay for patients with CHD, stroke, and CHF in 1999 were 3 days, 4 days, and 4 days, respectively, each of which was two days shorter than comparable hospital stays in 1993. These declines are most likely due to medical advances and managed care's efforts to control costs.

From 1993 to 1999, CHD hospitalization rates for males and females have decreased, particularly since 1996, but rates have remained relatively stable for cerebrovascular disease and congestive heart failure hospitalizations (Fig. 3). Although male hospitalization rates are significantly greater than female rates, actual numbers of hospitalizations are higher for females with cerebrovascular disease and congestive heart failure (Table 2).

Compared to other race and ethnic groups, black, non-Hispanics have significantly higher hospitalization rates for cerebrovascular disease and congestive heart failure, whereas white non-Hispanics have higher rates for CHD (Fig. 4). The latter is true for males only (data not shown). Hispanics tend to have lower CVD hospitalization rates. This correlates with their lower mortality rates.



Risk Factors



Besides the many people who already have one or more types of CVD, many more are at risk for developing the disease. Inherent and modifiable factors have been identified that are associated with an increased risk of developing CVD. CVD-associated risk factors that cannot be changed include positive family history, increasing age, male gender, and black race. Although these factors cannot be modified, their presence helps identify those at greatest risk. Major risk factors that can be modified, either by lifestyle changes or through medication, include cigarette smoking, high blood cholesterol levels, high blood pressure, diabetes, physical inactivity, and being overweight or obese. CVD risk factors tend to cluster, and the more risk factors that a person has, the greater the likelihood of developing CVD.

TABLE 2. CARDIOVASCULAR DISEASE HOSPITALIZATIONS
Connecticut, 1999

	Coronary Heart Disease Hospitalizations		Cerebrovascular Disease Hospitalizations		Congestive Heart Failure Hospitalizations	
	Number	AAHR*	Number	AAHR*	Number	AAHR*
Males	14,238	928.4	4,351	292.1	4,594	312.6
Females	9,049	435.5	5,031	230.4	5,011	222.1
All	23,287	657.9	9,382	256.1	9,605	258.9

* AAHR refers to age-adjusted hospitalization rates.

Note: nH refers to non-Hispanic.

A positive family history of CVD is often considered a risk correlate.[11] Its independent effect is difficult to ascertain because familial influences on CVD risk status tend to be mediated in part through blood pressure and blood cholesterol and indirectly through diet.

Similarly race and ethnicity are risk markers, rather than risk factors. Race and ethnicity are constructs used by health researchers to reflect socially distinct groups who share certain cultural, linguistic, socioeconomic, and/or other characteristics. They are used to identify high-risk populations who may also be affected by racism, segregation, and discrimination.[12]

Obesity and physical inactivity exert much of their adverse influence on the development of CVD through the other major risk factors. Nevertheless, they are important modifiable, contributory factors. The remaining modifiable risk factors have been shown to have independent effects on CVD.

Smoking increases the incidence of all major forms of heart disease and stroke. In 1998-1999 more than 1 in 5 Connecticut adults indicated that they smoked cigarettes (Table 3). The rates are highest (35%) in the youngest adult age group (18-24 years old), decreasing to 11 percent in the 65-and-older age group.[13] The unfavorable smoking patterns among the younger age groups may contribute substantially to the future burden of CVD.

Elevated low density lipoproteins (LDL) and low levels of high density lipoproteins (HDL) are risk factors for the development of CVD. Total cholesterol level is a less informative measure because it includes both LDL and HDL, which have opposite effects. Nevertheless, a high total cholesterol level is a major risk factor. During 1998-1999, 80 percent of Behavioral Risk Factor Surveillance System respondents in Connecticut reported ever having their cholesterol levels tested. Of those tested, 27 percent indicated that they had been told that their cholesterol was high (Table 3).

TABLE 3. CVD RISK FACTORS

Risk Factor	Percent Reporting Presence of Risk Factor*	CHD Relative Risk for Males⏏ (95% CI)	CHD Relative Risk for Females⏏ (95% CI)
Cigarette/tobacco smoking	22%	1.6 (1.4, 1.8)	1.8 (1.5, 2.1)
High blood cholesterol	27%	1.4 (1.2, 1.6)	1.1 (0.9, 1.2)
High blood pressure	22%	1.5 (1.3, 1.7)	1.5 (1.3, 1.8)
Diabetes	4%	1.9 (1.5, 2.5)	2.4 (1.9, 3.0)
Being over-weight or obese	51%	1.3 (1.1, 1.5)	1.4 (1.2, 1.6)
Physical inactivity	80%	N/A	N/A

⏏ Source: Bittner, 1994.[14]
CI = Confidence interval.
N/A = Not available.

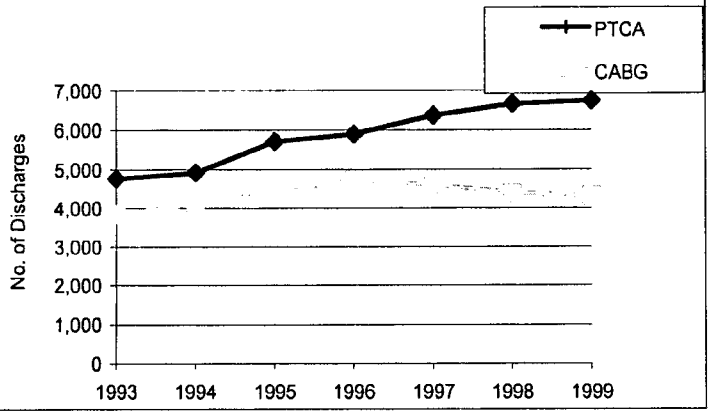
High blood pressure is also a major risk factor for heart disease and stroke. It is associated with a 50 percent increase in CHD risk over those without the condition. It is also the most important treatable risk factor for stroke. Most estimates for hypertension indicate a relative risk of stroke of approximately 3-4.[15] In 1998-1999, 22 percent of Connecticut adults reported that they had high blood pressure diagnosed by a health professional (Table 3). Development of high blood pressure is more likely to occur in people who are overweight and physically inactive, use alcohol heavily, or have excessive salt intake. The prevalence of being overweight or obese has increased significantly in Connecticut in the past decade. Diets high in saturated fat combined with sedentary lifestyles lead to excess weight. Nearly 63 percent of Connecticut males are considered overweight versus 40 percent of females. More than 70 percent of blacks are deemed to be overweight.[16] Being overweight affects the development of high blood pressure and diabetes, which, in turn, are important risk factors for heart disease and stroke.

Physical activity is beneficial in reducing CVD risk by helping to reduce body weight and by improving cholesterol levels, blood pressure, and blood sugar levels. Yet, nearly 80 percent of Connecticut adults have no regular physical activity (Table 3).

Diabetes is a significant risk factor for the development of high blood pressure, stroke, and heart disease, particularly in women. Of the modifiable risk factors, diabetes has the highest relative risk (Table 3). Diabetes not only increases the incidence of CVD but adversely influences outcomes as well - individuals with diabetes have a higher mortality rate from heart disease.

The high prevalence of major risk factors continues to contribute to the high rates of heart disease and stroke in Connecticut. Among Connecticut adults aged 18 and older, 93 percent reported having at least one of the six modifiable CVD risk factors and 28 percent reported having at least three.[17] This does not bode well for the future when the latent effects of the risk factors will manifest themselves in the form of CVD or other preventable disorders.

Prevention



Preventive measures for heart disease and stroke include screening for existing risk factors, lifestyle modifications, or pharmacologic interventions. Early intervention will lessen the severity of risk factors that are the result of the non-modifiable factors of aging and genetics. Recommended modifications include smoking cessation, weight management, increasing physical activity, incorporating a diet low in salt and saturated fat and rich in fruits and vegetables, and treating high blood pressure and high cholesterol levels.

For women with no known CHD, the preventive role of hormone replacement therapy (HRT) is not well established. In secondary prevention, HRT has not been shown to reduce death or morbidity among women with established CHD, and therefore is not recommended for this purpose.[18] Although several clinical trials have shown cholesterol-reduction therapy to be effective for primary prevention of CHD in patients at high absolute risk, the use of such therapy in patients at low-to-moderate risk is still under investigation.[19] However, cholesterol-lowering agents, such as statins, have proven to be efficacious in secondary prevention of CHD, which, in turn, may also result in stroke prevention. Other accepted secondary preventive measures for CHD include the use of aspirin, beta blockers, angiotensin-converting enzyme (ACE) inhibitors, and revascularization procedures.

CHD Treatment: Revascularization Procedures

Revascularization procedures are surgical procedures, such as coronary artery bypass grafting (CABG) and percutaneous transluminal coronary angioplasty (PTCA), that provide for a new, additional, or augmented blood supply to the heart. They are effective, but invasive and costly, treatments for coronary heart disease. In Connecticut, the number of PTCAs continues to grow while the number of bypass procedures has started to decline (Fig. 5). Cost is one likely explanation for this divergence. Average hospitalization charges for CABG procedures are approximately $44,000 compared to $21,000 for PTCAs; and patients' hospital stays are on average 10 days versus 3 days, respectively. Another explanation for the increase is that patients, who initially received angioplasties, are being readmitted for repeat procedures due to restenosis of their arteries. Implantation of a drug-coated stent into the blocked artery may help to alleviate this problem.[20]

FIGURE 5
No. of Discharges Receiving Revascularization Procedures
Connecticut, 1993-1999

Studies have used hospitalizations for acute myocardial infarctions (AMI) as a proxy for the incidence of heart disease because those with the condition will seek care, and there is consensus regarding the necessity for admission.[21] For patients presenting with acute myocardial infarctions in Connecticut, women received fewer revascularization procedures than men. During the period 1997-1999, 20 percent of female AMI discharges received PTCA and 9 percent had CABG surgery whereas 28 percent of male AMI discharges had PTCA and 12 percent CABG. Women were older than men (73 vs. 66 years of age on average, respectively) and tended to have more comorbidities. Even after controlling for age, women received fewer procedures. It is unknown whether women with AMI are being less aggressively treated or whether they have fewer clinical manifestations warranting revascularization.

Economic Burden

Not only is CVD a considerable health burden, it is also a significant economic burden, which will continue to grow as the population ages. In the United States, the estimated annual cost of CVD is nearly $300 billion or $1,100 per person. This figure includes direct costs of health expenditures (60%) and indirect costs of lost productivity resulting from illness and death (40%). Assuming that disease rates and per person expenditures in Connecticut are the same as those nationwide, the estimated annual cost of CVD in Connecticut is $3.6 billion. The estimated annual costs of CHD, stroke, and CHF in Connecticut are $1.2 billion, $500 million, and $500 million, respectively. The use of expensive treatment, while often effective in delaying death from CVD, is likely to continue to increase the financial impact of this disease.

The majority of the cost for CVD is for inpatient hospitalizations. Total charges associated with 1999 CVD hospitalizations in Connecticut were close to $1.1 billion. The median charge was approximately $11,000. Sixty-six percent of the hospitalizations had Medicare as their expected payer. This percentage has remained relatively constant from 1993 through 1999. In 1993 only 7 percent of the CVD hospitalizations were covered by managed care organizations. By 1999 the percentage had more than doubled to 16 percent.

Conclusion

The considerable health and economic burdens of cardiovascular disease demonstrate the need to reduce its incidence, improve the treatment of its manifestations, and reduce its long-term disability and mortality. Although great advances have been made in treating CVD, changing one's habits remains the most effective way to stop the progression of the disease. Benefits arise from a low-fat diet rich in fruits and vegetables, increasing physical activity, and not smoking. Individual efforts, however, need to be promoted and supported by health programs and policies. For instance, heart healthy foods should be more readily available in school and workplace cafeterias; smoking prevention and cessation programs need to be supported by policies that address the social, economic, and commercial aspects of tobacco use; and more places need to be provided where children and adults can safely engage in physical activity. These endeavors will help individuals to lower cholesterol and blood pressure and to lose weight. Screening for risk of CVD, altering lifestyles, and receiving appropriate medical interventions provide opportunities to prevent CVD and to reduce related health expenditures.

Data Notes

Age-adjusted rates were computed by the direct method using the 2000 U.S. standard million population.

Charges associated with hospitalizations represent billed amounts and do not include physician fees. They do not necessarily reflect the actual costs of the services on the part of the providers nor do they represent the payments received.

ABSTRACT

BACKGROUND

Prompt reperfusion treatment is essential for patients who have myocardial infarction with ST-segment elevation. Guidelines recommend that the interval between arrival at the hospital and intracoronary balloon inflation (door-to-balloon time) during primary percutaneous coronary intervention should be 90 minutes or less. However, few hospitals meet this objective. We sought to identify hospital strategies that were significantly associated with a faster door-to-balloon time.

METHODS

We surveyed 365 hospitals to determine whether each of 28 specific strategies was in use. We used hierarchical generalized linear models and data on patients from the Centers for Medicare and Medicaid Services to determine the association between hospital strategies and the door-to-balloon time.

RESULTS

In multivariate analysis, six strategies were significantly associated with a faster door-to-balloon time. These strategies included having emergency medicine physicians activate the catheterization laboratory (mean reduction in door-to-balloon time, 8.2 minutes), having a single call to a central page operator activate the laboratory (13.8 minutes), having the emergency department activate the catheterization laboratory while the patient is en route to the hospital (15.4 minutes), expecting staff to arrive in the catheterization laboratory within 20 minutes after being paged (vs. >30 minutes) (19.3 minutes), having an attending cardiologist always on site (14.6 minutes), and having staff in the emergency department and the catheterization laboratory use real-time data feedback (8.6 minutes). Despite the effectiveness of these strategies, only a minority of hospitals surveyed were using them.

CONCLUSIONS

Several specific hospital strategies are associated with a significant reduction in the door-to-balloon time in the management of myocardial infarction with ST-segment elevation.

From the Departments of Epidemiology and Public Health (E.H.B., T.R.W., H.M.K.) and Medicine (J.H., Y.W., J.P.C., R.L.M., H.M.K.), Yale University School of Medicine; Yale–New Haven Hospital (B.A.B., J.A.M., S.A.R., J.P., H.M.K.); and Yale University School of Nursing (J.P.) — all in New Haven, CT; the University of Michigan Medical Center and the Ann Arbor Veterans Affairs Medical Center, Ann Arbor (B.K.N.); Kaiser Permanente and the University of Colorado Health Sciences Center, Denver (D.J.M.); and the Joint Commission on Accreditation of Healthcare Organizations, Oakbrook Terrace, IL (J.M.L.).

Prompt treatment increases the likelihood of survival for patients who have myocardial infarction with ST-segment elevation.[1-3] Hospitals can therefore influence the outcomes for such patients by developing and implementing systems and processes that minimize the interval between arrival at the hospital and the administration of reperfusion therapy. Since percutaneous coronary intervention (PCI) has become the preferred approach for treating myocardial infarction with ST-segment elevation,[4] hospitals are seeking ways to reduce the door-to-balloon time, defined as the time between arrival at the hospital and the first balloon inflation during PCI.

The importance of the door-to-balloon time is highlighted by its inclusion as one of the core quality measures collected and reported by the Centers for Medicare and Medicaid Services (CMS) and the Joint Commission on Accreditation of Healthcare Organizations. Concomitant with national efforts to improve the care of patients with acute myocardial infarction have been substantial improvements in performance on many core measures (such as the use of aspirin and beta-blockers). However, performance with respect to the door-to-balloon time continues to lag behind national standards,[4-6] which recommend an interval of 90 minutes or less. A minority of hospitals treat patients who present with myocardial infarction with ST-segment elevation within 90 minutes after their arrival,[7-10] and hospital performance has not improved substantially in recent years.[7]

Previous qualitative work has identified some common approaches among hospitals that have achieved a rapid door-to-balloon time.[11,12] However, it is not clear which strategies are most effective or how great their effect might be. We sought to identify operational and clinical processes for treating patients who have myocardial infarction with ST-segment elevation and to quantify the association of these measures with hospital door-to-balloon times.

METHODS

STUDY DESIGN

We conducted a cross-sectional study of acute care hospitals in the United States with the use of a Web-based survey to determine the internal processes for identifying and treating patients with myocardial infarction with ST-segment elevation who undergo PCI. Eligible hospitals were those that reported the door-to-balloon time as a CMS performance measure and had reported an annualized volume of at least 25 PCI cases during 2004. From the 818 eligible hospitals, we randomly selected 500 hospitals and contacted the chief executive officer, first by letter and then by e-mail, to explain the goals and procedures of the study and to request the hospital's participation. The chief executive officer provided the contact information for the person in the organization whom they deemed to be the most appropriate respondent for the Web-based survey. This protocol was approved by the institutional review board at the Yale School of Medicine.

MEASURES AND DATA COLLECTION

From the hospital contact person, we obtained information about specific hospital strategies relevant to the door-to-balloon time, using a survey developed from our previous qualitative study[11] (see the Supplementary Appendix, available with the full text of this article at www.nejm.org). We developed closed-ended, multiple-choice questions for each hospital strategy and field-tested the instrument for clarity and comprehensiveness before implementation. The questionnaire asked about strategies in place at the time of the survey (April through October 2005). The final instrument included 32 items concerning 28 key hospital strategies. Response categories included "no standard approach" for cases of partial adoption of certain practices.

The outcome was the door-to-balloon time for patients with myocardial infarction with ST-segment elevation who underwent PCI between April and September 2005. Data on individual patients were obtained from CMS. On the basis of CMS specifications,[13] we included all patients with myocardial infarction with ST-segment elevation who were treated with PCI, except those who were transferred from other hospitals. CMS validates these hospital quality data reports with the use of quarterly validation samples that are abstracted and compared with the reported data.

STATISTICAL ANALYSIS

For each of the 28 hospital strategies, we determined the number and percentage of hospitals in each response category, as well as the average of the median door-to-balloon times of those hospitals. To evaluate the association between specific

hospital strategies and the door-to-balloon time, we used hierarchical generalized linear models,[14] which account for the clustering of patients within hospitals. We used the logarithm of the door-to-balloon time in our analysis to reduce skewness. For bivariate comparisons, we constructed a separate model for each hospital strategy.

We constructed a multivariate model, including independent variables that added significantly to the fit of the overall model ($P<0.10$ with the use of the likelihood ratio test for nested models), and sequentially excluded the variables that contributed the least to the fit of the model. Although the correlations among variables were modest (Cramer phi coefficient, <0.20 for 92% of the correlations), two variables were particularly strongly correlated (Cramer phi coefficient, 0.87). These variables were the specialty of the physician who was responsible for activating the catheterization laboratory on day shifts and the specialty of the physician who had that responsibility for night-and-weekend shifts. Therefore, we created a separate dummy variable for the multivariate analysis, which indicated whether emergency medicine physicians were responsible for activating the catheterization laboratory on day shifts as well as on night-and-weekend shifts. We also examined the effects of several hospital characteristics (location, teaching status, number of staffed beds, type of ownership, geographic region, capability of performing coronary-artery bypass grafting [CABG], and participation or nonparticipation in a multihospital system). However, none of these variables materially changed the effects of hospital strategies on the door-to-balloon time, and each was removed from the multivariate model. In reporting the data, we used an alpha level of 0.05 as the criterion for the statistical significance of the estimated effects of individual hospital strategies on the door-to-balloon time.

To facilitate the interpretation of the estimated effects, we centered all independent variables on their means, so that the intercept represented the mean of all independent variables.[15,16] Hence, the effect of individual strategies on the door-to-balloon time was calculated as the difference between the door-to-balloon time of hospitals implementing the selected strategy and hospitals not implementing the selected strategy, assuming the average response on all other strategies. We used simulation techniques[17-19] to transform estimated effects and confidence intervals in log units back into their natural units (i.e., minutes). All analyses were performed with the use of SAS software, version 9.1 (SAS Institute) and Stata 9 (Stata).

RESULTS

HOSPITAL SURVEY

We received responses from representatives of 365 of the 500 hospitals contacted (73%) (Table 1). The responding persons for each hospital were typically quality management directors, although cardiovascular nurse managers and medical directors were also involved at many hospitals. Nonrespondent hospitals did not differ significantly from respondent hospitals in terms of the annualized number of PCIs performed, the number of staffed beds, teaching status, geographic region, or median door-to-balloon time; however, rural hospitals were significantly less likely than urban hospitals to respond ($P=0.02$), and for-profit hospitals were significantly less likely than government or nonprofit hospitals to respond ($P=0.01$). Among the 365 respondents, 3 hospitals did not report data with regard to door-to-balloon times to CMS during the study period and were excluded from bivariate and multivariate analyses; 2 additional hospitals were missing one or more responses to survey items and were excluded from the multivariate analysis.

HOSPITAL STRATEGIES

Figure 1 shows the frequency distribution of median door-to-balloon times for the hospitals studied. The range of median values was wide, with many institutions having median times that ex-

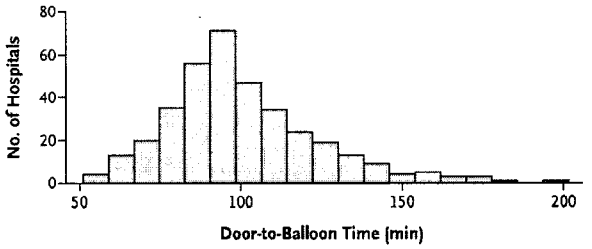

Figure 1. Frequency Distribution for Median Door-to-Balloon Times among Study Hospitals.

The median door-to-balloon time was calculated for each hospital in the study. The mean (±SD) of these median times was 100.4±23.5 minutes, which is considerably longer than the 90-minute interval recommended in the 2004 guidelines of the American Heart Association and the American College of Cardiology.[4]

* P values were calculated with the use of a hierarchical generalized linear model of the logarithm of door-to-balloon time with hospital strategy as an independent variable. ECG denotes electrocardiography, PCI percutaneous coronary intervention, and STEMI myocardial infarction with ST-segment elevation. P values are for the comparison between each survey response and the first listed response to each question.
† P values were calculated with the use of the Wald chi-square test.
‡ Data were missing from one survey respondent for this question.
§ Data were missing from two survey respondents for this question.

ceeded the 90-minute interval recommended in the 2004 guidelines of the American Heart Association and the American College of Cardiology.[4] The mean [±SD] of the median door-to-balloon times of all the hospitals was 100.4±23.5 minutes. There was also substantial variation in the prevalence of specific hospital strategies to expedite the door-to-balloon time. A number of strategies had significant unadjusted (bivariate) associations with the door-to-balloon time (Table 2).

The multivariate model identified six hospital strategies that added significantly to the fit of the model ($P<0.10$ for nested models) and were associated with a significantly lower door-to-balloon time. Some associations were particularly strong, indicating an estimated savings in the door-to-balloon time of 10 to 15 minutes (Table 3). These strategies were generally implemented in a minority of hospitals. Hospitals that implemented a greater number of effective strategies tended to have a shorter door-to-balloon time (Table 4).

Hospital practices regarding activation of the catheterization laboratory had a significant effect on the door-to-balloon time. The intervals were shorter for hospitals in which emergency medicine physicians activated the catheterization laboratory without consulting a cardiologist; those in which the catheterization laboratory was activated with a single call from the emergency department to a central page operator, who then paged both the interventional cardiologist and the catheterization laboratory staff; and those in which staff were expected to arrive in the catheterization laboratory either within 20 minutes or

21 to 30 minutes after being paged (P=0.002 for the comparison with an interval of 20 minutes or less and P=0.003 for the comparison with an interval of more than 30 minutes). In addition, hospitals that always had an attending cardiologist at the hospital had a faster door-to-balloon time than did hospitals without an attending cardiologist always on site.

Hospitals that used the results of electrocardiography that were called in or transmitted by emergency medical services to activate the catheterization laboratory while the patient was still en route to the hospital had significantly faster door-to-balloon times than did hospitals that waited for the patient to arrive before activating the catheterization laboratory (P=0.001). The hospitals that activated the laboratory while the patient was still en route also had significantly faster door-to-balloon times than did hospitals reporting that emergency medical services never performed electrocardiography (P=0.01). In addition, hospitals reporting that emergency medical services called in or transmitted the results of electrocardiography but also reporting various methods of handling such information had faster door-to-ballooon times than did hospitals that never received such information (P=0.01). Methods of handling the information may have included activating the catheterization laboratory while the patient was en route to the hospital, but with no set protocol for this procedure at the hospital. Finally, hospitals that provided real-time data feedback on the door-to-balloon time to staff members in the emergency department and catheterization laboratory had faster door-to-balloon times than those that did not (P=0.001).

One item in our survey requested an estimate of how frequently in the previous 6 months the catheterization laboratory had been activated for PCI but then had not been needed. This question was used to evaluate the effect of specific hospital policies on the frequency of such false alarms. The median number of false alarms that was reported among hospitals in which emergency medicine physicians activated the catheterization laboratory was 2 (interquartile range, 1 to 4), as compared with 1 false alarm (interquartile range, 0 to 3) for all other hospitals. Among hospitals using electrocardiographic data obtained en route to activate the catheterization laboratory, the median number of false alarms was 2 (interquartile range, 1 to 4) in the previous 6 months.

Table 4. Door-to-Balloon Time According to the Number of Key Strategies Used.*

Number of Key Strategies	Hospitals with the Number of Key Strategies (N=362)	Average of Median Door-to-Balloon Times†
	no. (%)	*minutes*
0	137 (37.8)	110
1	130 (35.9)	100
2	56 (15.5)	88
3	31 (8.6)	88
4	8 (2.2)	79

* Since the number of hospitals using three or four strategies was small, the precision of the estimates may be limited.
† P<0.001.

Hospital policies regarding the performance and assessment of electrocardiography in the emergency department did not have a significant effect on the door-to-balloon time, in either bivariate or multivariate analyses. These policies included the use of written criteria for deciding which patients should undergo immediate electrocardiography, provision of formal training in the assessment of acute coronary syndromes for triage staff members in the emergency department, inclusion of dedicated electrocardiographic technicians in the emergency department, and provision of dedicated space for performing electrocardiography in the triage area. In addition, policies and practices related to transporting patients from the emergency department to the catheterization laboratory (e.g., timing and staff required) were not significantly related to the door-to-balloon time in multivariate analysis. Practices in the catheterization laboratory that were surveyed were also not significantly associated with the door-to-balloon time in either bivariate or multivariate analyses. These practices included rescheduling elective PCI cases as emergency PCI cases, leaving the catheterization laboratory prepared for the next PCI to begin promptly, involving cardiology fellows in performing PCI, and locating the catheterization laboratory on the same floor as the emergency department.

DISCUSSION

In a cross-sectional study of 365 acute care hospitals in the United States, we identified several hospital strategies that were strongly associated with the door-to-balloon time in the performance of PCI for patients with acute myocardial infarction with ST-segment elevation. In some cases, specific practices were associated with time savings of 10 to 15 minutes, a clinically important advantage in a group of institutions with a mean value of 100 minutes for median door-to-balloon times. Many of the strategies are not commonly used in hospitals in the United States, which may account in part for the relatively poor performance of such hospitals in meeting guidelines for the door-to-balloon time.

Although implementation of some of the advantageous strategies would require investment in new resources, other strategies that are currently used by only a minority of hospitals could be implemented with existing resources. For instance, having emergency medicine physicians determine whether a myocardial infarction with ST-segment elevation is present and activate the catheterization team without involvement of a cardiologist was strongly associated with a reduced door-to-balloon time but was used in only about 23% of hospitals during weekdays and in 27% of hospitals at night or on weekends. Furthermore, having the catheterization laboratory activated by a single call from the emergency department to a central page operator, who then paged both the interventional cardiologist and the catheterization laboratory staff, was strongly associated with a faster door-to-balloon time, but the single-call process was used in only about 14% of hospitals in this study. Research on the time to fibrinolytic therapy[20] and small, single-hospital studies of the door-to-balloon time[21,22] have also indicated that treatment is more rapid if emergency medicine physicians make the treatment decision without the involvement of a cardiologist. Nonetheless, most hospitals still involve a cardiologist in the decision to activate the catheterization laboratory.

In addition to the strategies that focus on processes within the hospital, the hospital's coordination with emergency medical services was strongly associated with the door-to-balloon time. Previous studies[23-25] have shown that performing electrocardiography en route to the hospital can reduce the door-to-balloon time, and the National Heart Attack Alert Program Coordinating Committee[26] has recommended increased use of such electrocardiographic services. In our study, the percentage of patients with acute coronary syndrome who underwent electrocardiography en route was not associated with the door-to-balloon time. Instead, it was the way that such electrocardiograms were used by hospitals that was important. Hospitals that activated the catheterization laboratory on the basis of electrocardiography performed while the patient was en route and those that had varied strategies to respond to electrocardiographic data transmitted from emergency medical services had an advantage. Determining the optimal approach for incorporating such electrocardiographic data into hospital processes to expedite the door-to-balloon time is an important area for future research.

False alarms were reported to be infrequent in our study, even at hospitals where emergency medicine physicians were responsible for activation of the catheterization laboratory on the basis of electrocardiography performed en route to the hospital. We were not able to obtain independent confirmation of the accuracy of the hospitals' estimates of false alarms. However, we have no evidence to suggest that these data are inaccurate, and we believe that perceptions about the number of false alarms are probably as important as is the true number of false alarms in determining whether noncardiologists are permitted to activate the catheterization laboratory. This issue may be clarified by further study.

Implementation of other strategies that were associated with faster door-to-balloon time may be more complex. The presence of an attending cardiologist at the hospital at all times was associated with a significantly faster door-to-balloon time. These strategies may be impractical or prohibitively expensive to implement in many hospitals.

Several considerations are important in interpreting our results. First, the survey data were reported by a single respondent at the hospital, and the reported policies and practices were not independently confirmed. However, respondents were selected by the chief executive officer of each hospital as the person who was most familiar with activities in this area, and the questions were field-tested before their use to ensure their clarity and completeness.

Second, the hospitals were restricted to those that reported the door-to-balloon time as one of their CMS performance measures. These hospitals may have been more aggressive than others in their efforts to reduce the door-to-balloon time. Therefore, the prevalence of some strategies may be overestimated, but even for this group, the overall rates were low for most of the strategies. In addition, it may not have been possible to detect the influence of some practices because of a high prevalence of the preferred practice (e.g., 97% of surveyed hospitals do not wait for laboratory and radiographic results to activate the catheterization laboratory). Nevertheless, the respondent hospitals did reflect a spectrum of performance in the door-to-balloon time.

Third, with the observational study design, we could not determine whether some of the strategies identified were surrogates for unmeasured care processes that might have been important contributors to a reduced door-to-balloon time. The processes tested, however, emerged from qualitative studies[11,12] and have strong face validity for a causal relationship. In addition, some strategies may be important in particular institutions but not across the full sample, and our results should not inhibit innovations that may be effective in particular settings.

Finally, we were unable to examine efforts that may reduce the time from the onset of symptoms to admission or the time after arrival at the first hospital to balloon inflation for patients who were transferred to a hospital in which PCI is performed. These are important topics for future study, because delays in reperfusion therapy are commonplace for transferred patients.[27]

In conclusion, this study used survey information from 365 acute care hospitals to determine which specific policies and practices were in use for facilitating rapid PCI in patients with acute myocardial infarction with ST-segment elevation. These policies and practices, as reported, were correlated with data on individual patients with regard to the door-to-balloon time, permitting the identification of hospital strategies associated with the most prompt performance of this critical intervention.

Reducing the Door-to-Balloon Time for Myocardial Infarction with ST-Segment Elevation

Mauro Moscucci, M.D., and Kim A. Eagle, M.D.

It has been 27 years since the initial report of successful reperfusion of occluded coronary arteries with thrombolytic therapy in patients with acute myocardial infarction,[1] and 20 years since the initial report of the feasibility and safety of primary percutaneous coronary intervention (PCI) in the same setting.[2] During the past decade, primary PCI has gradually emerged as the preferred treatment strategy for acute myocardial infarction with ST-segment elevation.[3,4] However, for both primary PCI and thrombolytic therapy, analyses have consistently shown that timely reperfusion remains a key component in improving the survival of patients.[5-7]

For primary PCI, the standard approach to assessing the promptness of intervention is to measure the "door-to-balloon time," defined as the interval between the time a patient arrives in the emergency department and the first inflation of an angioplasty balloon in the occluded coronary artery. On the basis of data from clinical trials and registry analyses, a door-to-balloon time of less than 90 minutes recently was established as the benchmark for primary PCI.[8]

All that said, the shift from thrombolytic therapy to primary PCI has added new challenges in the already complex emergency management of acute myocardial infarction. These challenges go beyond the prompt recognition of myocardial infarction and the initiation of therapy in the emergency department. Essential steps include "activation" of the cardiac catheterization laboratory (a term that incorporates notification of interventional cardiologists and other personnel and preparation of the laboratory for the procedure), as well as transportation of the patient from the emergency department to the laboratory, preparation of the patient, and initiation and performance of the procedure itself. Recent surveys have shown that only about 20% of hospitals across the United States have been able to reach the 90-minute benchmark. Although a recent study suggested that a particular professional "culture" is needed within hospital systems to achieve optimal performance in reperfusion therapy with primary PCI,[9] relatively few objective data have been published regarding the potential benefit of specific strategies for reducing the door-to-balloon time.

In this issue of the *Journal*, Bradley and colleagues provide the results of a qualitative–quantitative analysis aimed at identifying hospital strategies that are associated with shorter door-to-balloon times for patients undergoing primary PCI.[10] The authors surveyed 365 hospitals with a questionnaire that included 32 closed-ended items identifying 28 key hospital strategies that influence the care of patients with acute myocardial infarction with primary PCI. The relationship between hospital responses and the door-to-balloon time of individual patients was then evaluated with the use of hierarchical modeling, with hospital strategies as explanatory (or independent) variables and door-to-balloon times as the dependent variable.

Several simple strategies emerged as important correlates of shorter door-to-balloon times. These strategies included activating the cardiac catheterization laboratory on the basis of electrocardiography performed while the patient is en route to the hospital, having emergency department physicians activate the catheterization laboratory rather than waiting for a cardiology consultation, activating the catheterization laboratory with a single call to a central page operator, expecting staff to arrive in the catheterization laboratory within 20 minutes (as compared with more than 30 minutes), having an attending cardiologist always on site, and providing real-time (within 1 week) data feedback with staff in the emergency department and catheterization laboratory on door-to-balloon times for patients who were recently treated. The amount of time saved with each strategy ranged from 8.2 minutes to 19.3 minutes.

It should be noted that short of having staff on call in the hospital or having the appropriate cross-training of personnel from different areas, the expectations that staff will arrive in the catheterization laboratory within 20 minutes after notification and that an attending cardiologist will always be on site may be difficult to achieve on a wide scale. Such practices would probably involve a trade-off between the optimal response time on one side and higher costs and possible personnel dissatisfaction on the other. However, all the other strategies that worked in this study

Downloaded from www.nejm.org at SAINT MARYS HOSPITAL LIBRARY on August 5, 2008 .

0456
09/15/08

should be achievable by most hospital systems. In particular, activation of the catheterization laboratory on the basis of electrocardiographic data obtained before admission, the use of a single page for activation of the catheterization laboratory, and allowing physicians in the emergency department to activate the catheterization laboratory (thus bypassing the not-uncommon sequence of contacting the primary care physician, the cardiologist, and then the interventional cardiologist) are simple and safe steps that seem to have an important effect on reducing the door-to-balloon time. The price to pay is the occasional false alarm or inappropriate activation, which was quite rare in the study by Bradley et al., with a median of two false alarms over a 6-month period.

The data supporting the effect of the 90-minute benchmark on survival, its inclusion as a quality indicator in the practice guidelines, and the emergence of pay for performance for achieving this goal are creating important incentives for hospital systems to reach this standard. In addition, a recent ruling by a coroner's jury in Illinois provides an additional sobering reminder of the potential legal implications of treatment delays.[11] In that ruling, the jury found that the death of a patient who had spent nearly 2 hours in an emergency department waiting room before proper diagnosis and treatment of a heart attack constituted a potential homicide.

It is now time to act. The Centers for Medicare and Medicaid Services, the American College of Cardiology, the American Heart Association, the National Quality Forum, and many other public and private groups are aligned to move forward with efforts to improve the time to reperfusion for patients with acute myocardial infarction with ST-segment elevation. Ultimately, these efforts will lead to improved survival for our patients.

Dr. Moscucci reports receiving consulting fees from Pfizer and Boston Scientific, lecture fees from Pfizer, and grant support from Cordis and Blue Cross–Blue Shield of Michigan. No other potential conflict of interest relevant to this article was reported.

Conflict of Interest — or Conflict of Priorities?

Elizabeth G. Nabel, M.D.

Whenever conflict of interest is mentioned in the context of clinical research, we tend to think of financial interests that may influence the ability of a person — particularly, a member of an institutional review board (IRB) — to make impartial decisions about the risks and benefits of a protocol. However, other interests are equally important elements of the clinical research enterprise. Research volunteers are vitally interested in their personal health, industry is strongly motivated to develop new diagnostics and therapeutics, and government entities are pledged to ensure proper oversight and conduct of research involving human subjects. Above all, maintaining

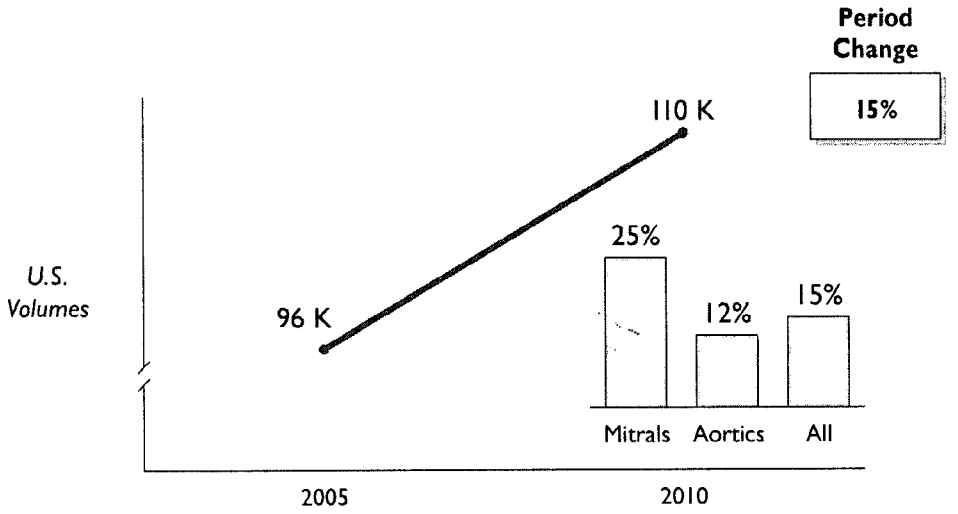
CABGs to Steadily Decline Through 2010

Long the bastion of cardiac program prosperity, CABG volumes have experienced massive declines since the launch of drug-eluting stents. Unfortunately, with past serving as prologue, the Roundtable anticipates that these decreases will continue through the end of the decade. While an aging population and a shift toward concomitant CABG/valve surgery will help to boost volumes, these factors will not overpower the continued migration of CABG cases to drug-eluting stents. More specifically, the line graph below outlines three potential scenarios for future CABG volumes, with the middle line representing the most likely scenario of a volume decrease of 21 percent between 2005 and 2010.

Future Forecast—CABG

All Cases, 2005–2010

Utilization Drivers



Barriers	Inducements
• Continued shift of "traditional" CABG cases (e.g., diabetics, bifurcated lesions, etc.) to DES • Decrease in saphenous vein re do cases • Reduction in in-stent restenosis cases referred to CABG • Little progress toward minimally invasive CABG adoption and penetration	• Population growth • Increase in valve cases with concomitant CABG • "Failed" restenosis cases treated with DES

Source: Innovations Center Futures Database; Cardiovascular Roundtable research and analysis.

Valves Continue to Be

Future Forecast— Valve Surgeries

All Cases, 2005–2010[1]

Utilization Drivers

Barriers	Inducements
• Technical challenge of mitral repairs • Lack of training opportunities to learn new skills • Failure of all surgeons to intervene at earlier stage in disease process	• Proliferation of valve surgery programs • Update to ACC/AHA valvular disease treatment guidelines expected to encourage earlier interventions in mitral regurgitation, aortic stenosis • Aging of population • Growth in heart failure population • Profitability of procedures • Continued growth in concomitant procedures

[1] Includes isolated valve and combined valve-CABG cases. Isolated mitral surgeries and isolated aortic surgeries 53% and 49% of total 2003 surgeries, respectively.

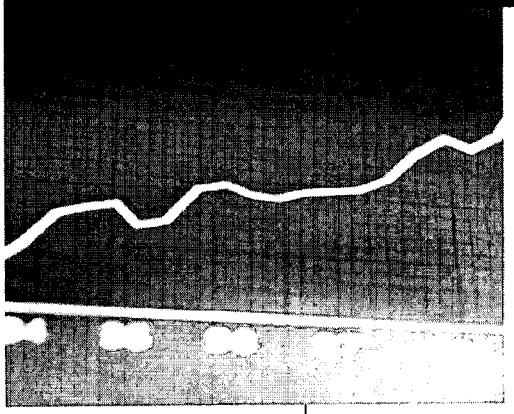
COMMUNITY HEALTH DATA SCAN FOR CONNECTICUT

A Report Commissioned by the Connecticut Health Foundation



March 2007

0461
09/15/08

EXECUTIVE SUMMARY

INTRODUCTION

The *Community Health Data Scan for Connecticut* was developed by the Connecticut Health Foundation (CHF) for several purposes: to help the foundation set priorities for funding programs and policy studies; to help citizens better understand a range of key health risk, health care and health outcome issues; and to provide state policy-makers and community leaders with information that can be used in developing sound public policy. The *Data Scan* reports quantitative data on the social characteristics, health and well-being of Connecticut's residents gathered from a variety of sources at the federal, state and town levels, as well as from non governmental sources. Some data presented in the analyses will be superseded in the near future, indeed, by the time of publication. Indicators were selected that typically change only slowly over time, such that the major study conclusions are unlikely to be affected. This document is not intended to be an exhaustive report on all possible health indicators for Connecticut.

Racial and ethnic disparities are one of the main concerns investigated in the *Data Scan*. This issue provided a consistent theme for the analysis, along with a report of data on different kinds of communities arrayed in Health Reference Groups (HRGs). The *Data Scan* provides an analysis of the data, prioritizes areas for health promotion effort and includes six recommended focus areas. This report does not focus on children's mental and oral health since CHF is already addressing these problems and other reports focus on these topics.

0462
09/15/08

ADVISORY COMMITTEE ROLE

The CHF Advisory Committee provided suggestions and possible measures to be investigated, emphasizing the need to track health disparities among racial and ethnic groups.

ORGANIZATION OF THE EXECUTIVE SUMMARY

The Executive Summary is organized to present the basic methods used in the study, including an innovation called Health Reference Groups (HRGs), and findings and recommendations in six priority areas.

MEASUREMENT SCAN METHODOLOGY

The *Data Scan* investigated six sources of data:

1. Relevant Connecticut state government web sites
2. Key Connecticut state agency data available offline
3. U.S. Census Bureau datasets available online and via CD-ROM
4. Federal web sites containing state-level data
5. Data defining state and federal legislative districts
6. Data from other agencies, e.g., Boys and Girls Clubs, Jack and Jill Clubs

THE INDICATORS

The many quantitative indicators for the report are summarized in more than 170 tables and figures.

HEALTH REFERENCE GROUPS

The *Data Scan* uses a principal methodology of HRGs to report data. These HRGs were especially useful in considering small towns where the community size and indicator counts would be too small to obtain reliable estimates, or where Connecticut agencies would suppress the data for reasons of confidentiality.

Six HRGs were formed via statistical cluster analysis. These clusters were named: 1) Urban Centers (the three largest cities: Bridgeport, Hartford and New Haven); 2) Manufacturing Centers; 3) Diverse Suburbs; 4) Wealthy Suburbs; 5) Mill Towns; and 6) Rural Towns. A map showing the towns and HRG clusters is in the Executive Summary Appendix. Additional town-level data and maps are available for some indicators at www.cthealth.org. A list of the towns in each HRG is in Appendix A, and a detailed description of the HRGs is in Appendix B.

EXECUTIVE SUMMARY TABLE 1: HEALTH REFERENCE GROUPS AND THEIR POPULATIONS

HEALTH REFERENCE GROUPS	1	2	3	4	5	6
DESCRIPTIVE	Urban Centers (UC)	Manufacturing Centers (MC)	Diverse Suburbs (DS)	Wealthy Suburbs (WS)	Mill Towns (MT)	Rural Towns (RT)
Number of Cities/Towns	3	10	15	27	39	75
Total Population	384,733	662,398	587,504	487,620	698,517	584,793
Average City/Town Population Size	128,244	66,240	39,167	18,060	17,911	7,797
Percentage of Connecticut Population	11.3%	19.5%	17.3%	14.3%	20.5%	17.2%

Source: U.S. Census 2000, SF1: Table P1.

RACE AND ETHNICITY

The author made a considerable effort to define Connecticut populations in racial and ethnic terms following, where possible, requirements of the U.S. Census Bureau and the federal Office of Management and Budget (OMB) Directive 15 (1997 Revision).[1]

POPULATION CHANGE

Any discussion of health priorities should take into account the growth pattern in the population. Connecticut's population will change markedly over the next 25 years, increasing between 2000 and 2025 and then remaining stable through 2030. The total change between 2000 and 2030 is projected at 8.3 percent.

The population will also change in composition. Projections show that there will be virtually no growth in the "white race" population through 2025 (+2.5 percent). The "black race" population is expected to increase by more than 50 percent, the "Hispanic ethnicity" population by 99 percent, and the "Asian race" population by 113 percent.

The Hispanic population is currently the youngest group (74 percent are under 35), followed by the black race population (59 percent), the Asian race population (55 percent), and the white race population (41 percent).

KEY RISK FACTORS FOR MORBIDITY AND MORTALITY

Another context for examining the health data is research-based knowledge of the major risk factors for leading causes of morbidity and mortality, such as smoking, diet and exercise, alcohol abuse, microbial agents, toxic agents, firearms, sexual behavior, and motor vehicle crashes. Many of these issues are analyzed in the report. The report also considers problems of health care access, health care quality and environmental health.

A SYSTEMS VIEW

Health-related behaviors can be understood only in their relevant contexts — including health care and health promotion access, utilization and quality; peer group and cultural norms; the physical environment — and by examining both assets and barriers to good health.

0464
09/15/08

Six Priority Areas and Recommendations

The *Data Scan* suggests six priority areas. The detailed findings and rationale are provided in the *Data Scan*, and they are summarized in Chapter 11, Summary and Recommendations.

1. FOCUS ON THE HEALTH REFERENCE GROUPS AND RACIAL/ETHNIC GROUPS IN GREATEST NEED

The three Urban and 10 Manufacturing centers in Connecticut need the greatest health-promoting investments. Within these communities, black/African American and Hispanic residents are in greatest need.

2. FOCUS ON DIABETES AND OTHER CONDITIONS IN THE METABOLIC SYNDROME

Risk factors for diabetes and related conditions — called the metabolic syndrome — are increasing nationwide and are prevalent in Connecticut in several populations, especially in the black/African American population. To address the problem effectively, public policy solutions must be developed and prevention-focused support given to organizations that serve youth and adults. It will be important to focus on health care access and quality (e.g., better primary care access and utilization) and for primary care to focus on the key metabolic syndrome issues.

3. FOCUS ON ENSURING A MEDICAL HOME FOR ALL CONNECTICUT RESIDENTS

Overuse of emergency department (ED) care and many hospital admissions could be avoided if every Connecticut resident had, and used, a primary care "medical home." Reducing avoidable ED and hospital utilization will require a whole systems approach focused on increasing access to and comfort with the language and cultural surroundings of the medical home; using the medical home to discuss issues of chronic disease and child and youth safety; and promoting adherence to medical regimens prescribed in the primary care setting.

4. FOCUS ON THE BINGE DRINKING AND SMOKING CULTURE

Smoking and binge drinking are major contributors to many health problems and to premature mortality. The youth and young adult white population is especially at risk for binge drinking and smoking, and these behaviors may spread to immigrant populations as they acculturate. Methods of changing the culture of chronic and binge drinking and smoking could include: increasing the level of information about the signs and consequences of alcohol abuse and tobacco use; supporting stronger coverage of the tobacco ban for small workplaces; and supporting changes in the law that would clarify which state level agencies are charged with enforcement of tobacco-related regulations.

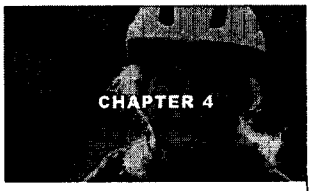
5. FOCUS ON YOUTH RISKS AND OPPORTUNITIES

Major youth health risks include sexually transmitted diseases (STDs), teen pregnancy, lack of use of seat belts and bicycle helmets, and child abuse. There is a need for broad initiatives on child and youth risk taking and safety, focused especially on the Urban and Manufacturing centers, and with black and Hispanic children and youth, who are most at risk regarding a variety of safety and risk issues. Some of these problems could be addressed through support for focused initiatives by youth out-of-school programs.

6. IMPROVE THE HEALTH DATA SYSTEM

The health data system could be improved in many areas to provide data where none currently exists and make data more easily available to the public. Issues that need to be addressed include: data access, data delays, mapping information, health observations, race and ethnicity categories, health care quality indices, mental health data, out-of-school data, and documentation about the data (meta-data).

CHAPTER 4



HEALTH RISK AND HEALTH-PROMOTING BEHAVIORS

This chapter considers a selection of health risk and health-promoting behaviors in Connecticut. These include:

- School performance, dropout and suspension data
- Child endangerment
- Crime data
- Travel safety
- Youth risk behavior
- Sexually transmitted diseases
- Teen births
- Obesity, diet and exercise
- Drug use and abuse — drinking and smoking

0466
09/15/08

SCHOOL PERFORMANCE

School performance has been shown to correlate with health risk.[46] The Connecticut State Department of Education (SDE) has made available data on student performance on the Connecticut Academic Performance Test (CAPT) (Table 37); on high school graduation (Table 38); and school suspension and expulsion (Table 39). These data may identify groups of students "at risk" and disparities in risk.

TABLE 37: HIGH SCHOOL MATH PERFORMANCE ON CONNECTICUT ACADEMIC PERFORMANCE TEST (CAPT), 2006, BY HOME COMMUNITY HEALTH REFERENCE GROUP

Percentage Scoring Below Basic on CAPT, 2006, by Gender and Race/Ethnicity, For Students with Valid Test Scores Only								
Gender	Race/Ethnicity	HRG 1 (UC)	HRG 2 (MC)	HRG 3 (DS)	HRG 4 (WS)	HRG 5 (MT)	HRG 6 (RT)	State
Female	Asian	5.7	6.6	0.9	1.4	0.8	0.0	2.1
Male		18.9	6.3	3.4	2.1	2.3	2.2	4.1
Female	Black	26.9	24.9	14.6	13.7	17.9	16.7	22.5
Male		30.7	27.5	19.6	19.4	15.9	9.9	25.5
Female	Hispanic	23.0	23.6	15.5	5.4	18.6	7.8	20.5
Male		25.0	23.4	16.4	2.5	13.5	8.0	20.4
Female	White	10.4	8.2	3.9	1.4	4.1	1.9	3.4
Male		13.0	6.4	5.4	1.5	4.8	3.1	4.0
Percentage Without a Valid Test Score*								
Female	Asian	2.8	2.8	3.4	0.7	3.1	0.0	2.1
Male		7.5	3.1	3.3	1.4	2.2	2.1	2.7
Female	Black	10.2	4.3	5.1	3.8	6.4	3.2	6.9
Male		17.9	7.8	10.2	1.5	6.1	6.6	12.1
Female	Hispanic	13.8	8.0	4.6	1.5	2.3	3.8	8.5
Male		20.7	12.2	8.3	3.2	6.1	5.0	13.1
Female	White	5.5	3.4	2.4	1.4	2.0	1.6	2.0
Male		11.5	4.7	3.9	2.1	4.3	2.7	3.5

Source: SDE. Data are from a file supplied by SDE for 44,652 10th-grade students. Data in the table include 44,123 students (99 percent of all students) for whom gender, district and race/ethnicity could be identified and who were white, black, Asian, or Hispanic and who were not English Language Learners who took the math test with less than 10 months in a U.S. school.

**In Math, an invalid score includes: Absent, one or more sessions of Math, Special Modifications, Blank, (no responses and "blank" bubbled by the district administrator) Grade 10 retesters who previously met certification in Math, Medical Exempt and Skills Checklist (Special Education Only). (R. Mowrey, SDE; e-mail communication; October 2006). Statewide, most invalid scores are due to absentees.*

The data in Table 37 show that the below basic rates for black and Hispanic students with valid test scores are higher than the parallel below basic rates for white and Asian students. For black and Hispanic students, the highest below basic rates are in the Urban and Manufacturing centers.

Black and Hispanic students in the Urban Centers show significantly higher rates of invalid (e.g., absent, blank and skills checklist) test scores than other groups. Their invalid test rates are lower in all other Health Reference Groups (HRGs). Black and Hispanic male students have invalid tests significantly more than black and Hispanic female students in the Urban and Manufacturing centers.

0467
09/15/08

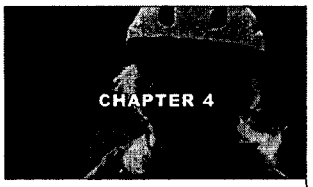
School Graduation and Dropout Rates

A measure of attachment to school is the high school graduation rate, and conversely, the school dropout rate, shown in Table 38 as calculated by the Connecticut State Department of Education (SDE) based on submissions by each school district. High school graduation rates for each HRG are in declining order: Wealthy Suburbs > Rural Towns > Mill Towns > Diverse Suburbs > Manufacturing Centers > Urban Centers. The Connecticut vocational-technical high school system shows a high graduation rate and a low dropout rate, according to the data reported to the SDE.

TABLE 38 : ACADEMIC HIGH SCHOOL GRADUATION PERCENTAGE AND CUMULATIVE DROPOUT RATE BY HEALTH REFERENCE GROUP

AREA	Graduation Percent, 2005	Cumulative Dropout Rate, Class of 2005
HRG 1 (3)-UC	74.1	16.4
Bridgeport	74.7	18.9
Hartford	72.3	14.3
New Haven	75.0	16.6
HRG 2 (10)-MC	85.8	10.9
HRG 3 (15)-DS	91.1	7.6
HRG 4 (27)-WS	97.5	1.9
HRG 5 (39)-MT	92.0	7.4
HRG 6 (75)-RT	95.3	4.4
Connecticut	90.1	8.3
CT Voc-Tech HS	97.3	1.8

Source: SDE, available at: http://www.sde.state.ct.us/public/cedar/cedar/grads/2005_Grad_Rate_by_Dist.xls and http://www.sde.state.ct.us/public/cedar/cedar/dropout/resources/ cumltve_dropout_rate_district.xls. Average graduation rates are shown for HRGs and Connecticut. Regional school districts assigned to an HRG according to the majority of towns in district. Most regional districts are comprised of Rural Towns. Only districts with both graduation rates, dropout rates and assignable to an HRG are included. Vocational-technical high schools not included in Connecticut total and are listed separately. The table accounts for 99.5 percent of Connecticut high school graduating students. The cumulative dropout rate is a class rate that reflects the proportion of students within a high school class who dropped out of school across four consecutive years. For example, the Class of 2004 Cumulative Dropout Rate = (2000-01 Grade 9 dropouts + 2001-02 Grade 10 dropouts + 2002-03 Grade 11 dropouts + 2003-04 Grade 12 dropouts), Grade 9 enrollment as reported on Oct. 1, 2000.



Suspension and Expulsion Rates

Another measure of school attachment is the suspension/expulsion rate, shown in Table 39, which varies significantly by HRG and by race/ethnicity.

TABLE 39: SUSPENSION AND EXPULSION (ALL TYPES) RATE PER 1,000 HIGH SCHOOL STUDENTS, FOR SCHOOL YEAR 2003-2004

AREA	White	Black	Hispanic	Asian	Total
HRG 1 (3)-UC	52	155	112	85	125
HRG 2 (10)-MC	47	150	119	32	90
HRG 3 (15)-DS	40	122	111	21	59
HRG 4 (27)-WS	30	64	39	28	32
HRG 5 (39)-MT	50	179	118	43	56
HRG 6 (75)-RT	52	113	62	15	53
Connecticut	45	143	110	31	65

Source: Analysis of file provided by the SDE, Summer 2005.

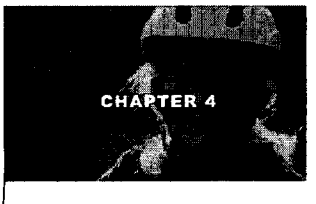
Asian students are least likely to be suspended or expelled, followed by white students, Hispanic students and black students, who are most likely to be suspended/expelled. Black and Hispanic students are least likely to be expelled in the Wealthy Suburbs. Black students are most likely to be suspended or expelled in the Mill Towns, Urban Centers and Manufacturing Centers. Asian students are most likely to be suspended/expelled in the Urban Centers.

The order of suspension/expulsion is Urban Centers > Manufacturing Centers > Diverse Suburbs > Mill Towns > Rural Towns > Wealthy Suburbs, although the rates for the Diverse Suburbs, Mill Towns and Rural Towns are virtually equal.

Three additional conclusions can be drawn from other available statewide suspension/expulsion data for all grades Pre-K – 12: Boys are much more likely to be sanctioned than girls; there are no significant race/ethnicity differences in the severity of sanction as indexed by the percent of students sanctioned who were expelled; and sanctioning rates and disparities in them are minimal in the primary years, maximal in the middle school years and decline again in the late high school years.

Table 40 indicates the relative segregation of schools in the Urban Centers — 89.3 percent of all public school students are black and Hispanic in these cities.

TABLE 40: BLACK AND HISPANIC STUDENTS AS A PERCENTAGE OF ALL STUDENTS, 2004



HRG 1 (UC)	HRG 2 (MC)	HRG 3 (DS)	HRG 4 (MT)	HRG 5 (MT)	HRG 6 (RT)
89.3	50.7	26.9	4.4	6.6	3.7

Source: SDE, CAPT Eligible Student File.

Summary of School-Based Indicators

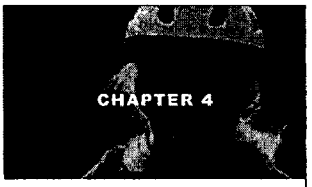
To the extent that the bond between students and schools can be measured by the indicators of CAPT test-taking (valid scores), CAPT passing, suspension/expulsion, and graduation rates, there are significant disparities by race and ethnicity and by gender. These disparities are accentuated in communities characterized by a high density of black and Hispanic students in the schools, as shown in the Urban Centers, and to a lesser degree in the Manufacturing Centers.

To put it another way, the communities with the fewest black and Hispanic students — the Wealthy Suburbs and the Rural Towns — are the most "protective" of them in the sense of helping to maintain a positive school-student bond and fostering school achievement. The Mill Towns are somewhat anomalous since they have a relatively low number of black students in school yet have a high suspension/expulsion rate for black students.

CHILD ENDANGERMENT

Reports to the Connecticut Department of Children and Families

The frequency of child endangerment reported to and substantiated by the Connecticut Department of Children and Families (DCF) in various regions and the state overall is another indicator of the threats to Connecticut's children. The DCF considers an individual to be a "child" if s/he is under 18, or under 21 and a client of the DCF. It classifies "accepted reports" of child endangerment as those reports made to the child abuse/neglect hotline that contain "allegations that meet the operational definition of abuse and/or neglect."[47] "Substantiated reports" are the accepted reports in which an investigation "resulted in a finding of reasonable cause to believe that neglect and/or abuse has occurred."[48]



DCF's Child Protective Services Division is responsible for investigating all reports of alleged child maltreatment throughout the state and arranging follow-up services as necessary. In a 2004 needs assessment analysis, DCF reported 3,796 open investigations and 14,431 ongoing services cases within Child Protective Services, for a total of 18,227 cases.[49]

Table 41 shows the rates of accepted and substantiated cases for fiscal years 2001-2005 combined. Child abuse rates are, in decreasing order: Urban Centers > Manufacturing Centers > Diverse Suburbs > Mill Towns > Rural Towns > Wealthy Suburbs.

TABLE 41: ACCEPTED AND SUBSTANTIATED CHILD ABUSE CASES, ANNUAL AVERAGE, FISCAL YEARS 2001-2005

AREA	Accepted Cases	Population 0-17	Accepted Cases Rate per 1,000	Substantiated	Substantiated Cases Rate per 1,000	Substantiation Percentage
HRG 1 (3)-UC	7,348	107,686	68.2	2118	19.7	28.8
Bridgeport	2,312	39,672	58.3	680	17.1	29.4
Hartford	2,897	36,568	79.2	676	18.5	23.3
New Haven	2,139	31,446	68.0	762	24.2	35.6

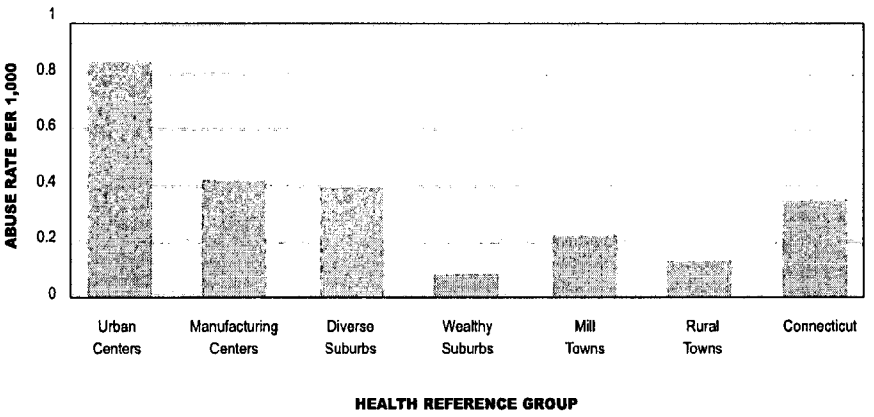
Connecticut	30,945	841,688	36.8	8450	10.0	27.3

Source: DCF; U.S. Census 2000, SF1:Table PCT 12.



Abuse Rates Using an Emergency Department Visit Indicator

The author examined child and adult abuse rates by HRG, using 2002-2003 Connecticut Emergency Department (ED) data from the Connecticut Health Information Management and Exchange (CHIME) system. The full report is included as Appendix F. Abuse was identified using ICD-9-CM, E967 code, "perpetrator of child and adult abuse."

Adjusted for age and gender differences, the ED visit rate for abuse was highest in the Urban Centers and lowest in the Wealthy Suburbs (0.85 per 1,000 vs. 0.09 per 1,000: a ratio of 9.7 to 1) as illustrated in Figure 9. The highest rate among children was found for 10- to 14-year-old females in the Urban Centers (1.75 per 1,000) — a rate 16 times that for females the same age in the Wealthy Suburbs, as shown in Table 42.

FIGURE 9: CHILD AND ADULT ABUSE: ANNUAL RATES OF EMERGENCY DEPARTMENT VISITS PER 1,000, ADJUSTED FOR AGE AND GENDER

Source: CHIME Database, Connecticut Hospital Association (CHA); U.S. Census 2000, SF1: Table P1.

Many more cases are reported to DCF than those that appear in and are coded in emergency departments. But the HRG patterns are similar. It also appears that female children are at greater risk for abuse than male children. Clearly, children need better protection, especially those in the Urban Centers, Manufacturing Centers, Diverse Suburbs, and Mill Towns, as shown in Table 42.

TABLE 42: INDICES OF ABUSE FOR CHILDREN AND ADULTS

AREA	DCF Accepted Cases per 1,000 Children 0-17	Emergency Department "Abuse" Visits (ICD-9-CM Code E967) per 1,000		Emergency Department "Abuse" Visits for All Ages, Age-Adjusted Rate per 1,000
		Male, 10-14	Female 10-14	
Urban Centers	68.2	1.16	1.75	.85
Manufacturing Centers	53.2	0.36	0.65	.42
Diverse Suburbs	43.8	0.26	0.34	.39
Wealthy Suburbs	9.8	0.08	0.24	.09
Mill Towns	32.0	0.06	0.11	.22
Rural Towns	19.8	0.05	0.05	.13

Source: CHIME Database, CHA; U.S. Census 2000, SF1: Table PCT 12.
Data Note: The differences among the HRGs would be due to underreporting in the Wealthy Suburbs and Rural Towns. This seems an insufficient explanation for the observed differences in that: several data sources yield similar differences; the patterning of gender differences could not be explained in this way; and the reporting bias would need to be very extreme to account for the level of the differences observed.

CRIME RATES

Crime is a significant health risk in several ways. First, it is directly implicated in injury and fatality. Secondly, a high incidence of even low-level crime may send a message about anti-social behavior as suggested by Wilson, Kelling, and Coles' "broken windows" theory.[50] Crime will escalate in a community if low-level crime — broken windows or other forms of vandalism — is seen as being accepted in the community or impossible to deter.

There may also be community disinvestment as capital "flees," leading to further social disorder and increases in health-demoting behavior. Research has shown the connections of "broken windows" to health outcomes such as elevated sexually transmitted disease (STD) rates even after controlling statistically for poverty and race.[51]

Crime in Connecticut varies substantially by HRG, as shown in Table 43.

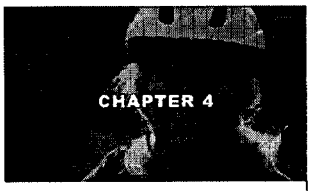


TABLE 43: ANNUALIZED CRIME REPORT RATE PER 1,000 RESIDENTS, 2002-2003

AREA	Population	Crimes Reported per 1,000 Residents
HRG 1 (3)-UC	384,733	76.1
Bridgeport	139,529	58.5
Hartford	121,578	92.6
New Haven	123,626	79.8
HRG 2 (10)-MC	662,398	39.5
HRG 3 (15)-DS	587,509	29.5
HRG 4 (27)-WS	487,620	13.0
HRG 5 (39)-MT	698,458	22.7
HRG 6 (75)-RT	584,847	12.1
Connecticut	3,405,565	30.0

Source: Crimes Analysis Unit, Connecticut State Police; U.S. Census 2000, SF1: Table P1. For some towns (e.g., New Haven) there may be several police organizations providing data, including New Haven police, Yale University police and Southern Connecticut State University police.

As with many other indicators, crime rates vary in decreasing order as follows: Urban Centers > Manufacturing Towns > Diverse Suburbs > Mill Towns. The Wealthy Suburbs and Rural Towns are lowest in overall crime rate. The HRG variation may be partly due to differences in age distribution, but this was not provable from the current data. Age-specific crime rate data are not available without considerable labor on the part of the Connecticut State Police unit responsible for the data, to bring together several databases.[52] Differences in age distribution cannot account for the vast disparity in crimes reported. The rate ratio of Urban Centers to Rural Towns is 76.1:12.1 = 6.3:1.

Related data are available on incarceration rates. According to analysis of U.S. Census 2000 data, there were 199 (white), 2,991 (black) and 1,669 (Hispanic) inmates per 100,000 residents, overall. The overall ratio of black to white confinement was 15.0:1 for Connecticut — ranking the state third in the nation — but just 6.6:1 for the United States as a whole. For Hispanic residents, the ratio was 8.4:1 for Connecticut but 2.4:1 for the United States as a whole.

For youth under 18 there were 56 (white), 334 (black) and 208 (Hispanic) residents confined per 100,000 residents. The overall ratio of black to white youth confinement was 6.0:1 for Connecticut — ranking the state eighth in the nation — but just 3.3:1 for the United States as a whole. For Hispanic youth, the ratio was 1.2:1 for Connecticut, but 1.5:1 for the U.S. as a whole.[53]

0473
09/15/08

TRAVEL SAFETY

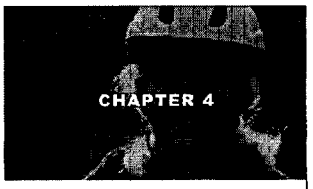
Several aspects of travel safety were examined for the *Data Scan*, including the use of seat belts, bicycle helmets, ED visits for bicycle injury, and the incidence of auto crashes with injury. These indicators show significant variation by HRG and race/ethnicity.

Seat Belt Use

Asian respondents have the highest overall rate of always or almost always wearing seat belts, as shown in Table 44. Their rates are significantly higher, being 10.2 percent above those of black respondents, 6.1 percent above those of white respondents and 6.6 percent higher than those of Hispanic respondents.

TABLE 44: SELF-REPORTED PERCENTAGE USING SEAT BELTS (ALWAYS OR ALMOST ALWAYS)

AREA	All Race and Ethnicity, Crude Rate	All Race and Ethnicity, Age-Adjusted Rate	White, Not Hispanic	Black, Not Hispanic	Hispanic	Asian, Not Hispanic
Bridgeport	87.9	87.8	91.3	89.1	82.0	
Hartford	86.0	87.5	85.3	84.4	88.9	
New Haven	86.7	86.3	87.9	75.8	88.4	
HRG 1 (3)-UC	86.9	87.0	88.3	83.8	86.7	
HRG 2 (10)-MC	88.9	89.0	87.8	84.4	90.5	94.9
HRG 3 (15)-DS	89.1	89.0	89.0			
HRG 4 (27)-WS	92.6	92.1	92.2			
HRG 5 (39)-MT	87.3	86.8	86.7	81.3	88.1	96.1
HRG 6 (75)-RT	90.7	90.4	90.5			
Connecticut	89.3	89.1	89.2	85.1	88.7	95.3



Source: Behavioral Risk Factor Surveillance System (BRFSS) Survey Data; DPH 1999-2003.
Note: All race and ethnicity specific rates are age-adjusted.
Blank cells indicate that data were not available due to small survey numbers or otherwise not calculated or available.

The data for the adult population are reasonably consistent for all groups — except black New Haven residents, of whom the sample size is small — falling within plus or minus eight points of the overall Connecticut average of 89.1 percent.

TABLE 45: USED A SEAT BELT NEVER OR RARELY, HIGH SCHOOL STUDENTS, 2005

GROUP	Total	Black	Hispanic	White
Total	11.4	18.0	15.1	9.1
Male	15.0	19.5	20.3	12.9
Female	7.5	16.6	10.9	4.9

Source: DPH, Planning Branch. Connecticut High School Survey, 2005. Available at: http://www.dph.state.ct.us/PB/HISR/CSHS.htm. Accessed Feb. 7, 2007.
Note: Percentages based on self-report of students who "never or rarely wore a seat belt when riding in a car driven by someone else." Students listed as "all other races" and "multiple races" are not included.

The youth data in Table 45 show some statistically significant differences in seat belt use rate between white students (9.1 percent never or rarely use) and black (18.0 percent rarely or never use) or Hispanic students (15.1 percent rarely or never use). There is also a statistically significant difference between Hispanic female and male use rates and white female and male use rates, but not between black female and male use rates. The data are reasonably consistent with the survey results presented below on bike helmet use.

Bike Helmet Use

Bike helmet use is another indicator of youth risk. Use of a helmet may indicate greater self-care or a greater degree of health-promoting parental supervision or differences in peer group norms.

TABLE 46: ADULT REPORT OF BICYCLE HELMET USE FOR CHILDREN AGES 5-16 WHO RIDE BICYCLES

AREA	All Race and Ethnicity, Crude Rate	All Race and Ethnicity, Age-Adjusted Rate	White, Not Hispanic	Black, Not Hispanic	Hispanic	Asian, Not Hispanic
HRG 1 (3)-UC	53.7	44.5	70.9	44.3	42.0	
Bridgeport	66.9	64.8				
Hartford	45.4	46.2				
New Haven	49.0	43.4				
HRG 2 (10)-MC	66.3	60.9	69.6	59.3	48.3

Note: All race and ethnicity specific rates are age-adjusted.
Blank cells indicate that data were not available due to small survey numbers or otherwise not calculated or available.

The results for bike helmet use reported by parents suggest relatively large and statistically significant differences in use rates by HRG and by race and ethnicity. Among children who ride bikes, black and Hispanic children show significantly lower use of bicycle helmets.

There are also bicyclist injury data for children and youth ages 5 to 19 developed from data in the CHIME emergency department database and shown in Figure 10. These data indicate highly significant gender differences for each HRG. They also indicate a significantly lower rate of ED visits for bicyclist injuries in the Wealthy Suburbs than for any other HRG. There are no significant differences among the other HRGs. These differences may be due to differences in helmet use, the "riskiness" of bicycle use, the overall level of bicycle use, and road conditions or other conditions of use.

Car Crashes

Car crashes with injury can result from a number of factors, including road conditions and congestion; weather conditions; driving behavior; crash protection access and use, such as air bags and restraint devices; and insurance fraud. The Connecticut Department of Transportation (DOT) maintains a database of all crashes, but there is incomplete reporting of cases not involving injury. The following analyses are therefore, based solely on crashes involving injury. Table 47 shows annualized average results for 2003-2004.

TABLE 47: CRASHES INVOLVING FATALITY OR INJURY BY CRASH LOCATION, RATE PER 1,000 POPULATION, ANNUAL AVERAGES 2003-2004

AREA	Total Population	Average Total Crashes With Injury	Total Crash Rate per 1,000	Interstate Crash Rate per 1,000	U.S. Route Crash Rate per 1,000	State Road Crash Rate per 1,000	Local Road Crash Rate per 1,000
HRG 1 (3)-UC	384,733	5,530	14.4	2.2	1.3	2.8	8.2
HRG 2 (10)-MC	662,398	6,976	10.5	1.4	1.3	3.0	4.9

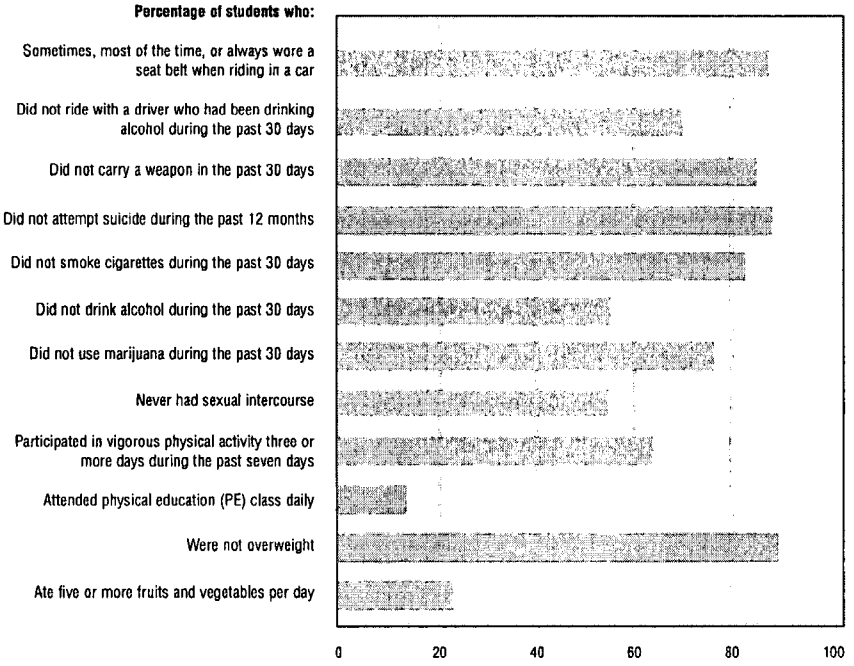
Source: DOT Accident Records Section; U.S. Census 2000, Table P1.

The data in Table 47 show that auto crash rates are significantly higher in the Urban Centers than in the other HRGs and that this difference is produced mainly by the difference in crash rates on local roads. This occurs despite that fact that Urban Center residents have far fewer vehicles per population than any other HRG and spend far less time commuting to work on nonpublic transportation (e.g., cars, vans and trucks) than residents of any other HRG. A caution in the interpretation of these crash injury statistics is that the DOT classifies crashes by the location of the crash, and the residential location of the driver is not available in electronic format.[54] This means that nonresidents of the Urban Centers, for example, may contribute to the crash rate in the Urban Centers because of a crash on an interstate highway in Hartford and that, conversely, residents of the Urban Centers may contribute to crashes in other HRGs. Whether these competing factors cancel out is unknown. The fact that the highest crash counts are on state or local roads and that national data indicates that "three out of four crashes causing death occur within 25 miles of home"[55] suggests that many accidents causing injuries are close to home and in the city or town of residence. But a statistical connection between crash site and residence cannot be absolutely demonstrated in the available data. "Miles-driven," a better denominator for crash rates than population, is also not available. Studies should be done to analyze the residential location and other characteristics of the drivers involved in injury-related crashes to ascertain whether there are significant differences among drivers residing in the various HRGs. This might lead to targeted driving safety campaigns.

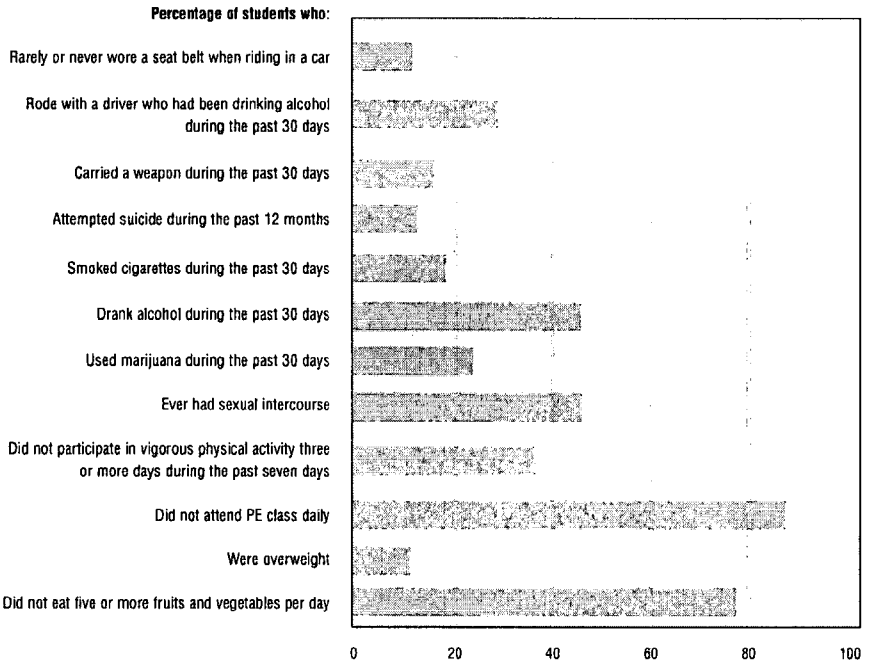
Age is related to the frequency of being a driver in a car crash involving injuries or fatalities. Rates rise from the early teen years through the late teens and early 20s. For each of the years 18–22, annualized rates based on 2003–2004 are 40 per 1,000 or higher (18 = 40; 19 = 44; 20 = 42; 21 = 41; 22 = 40). Rates decline rapidly in the late 20s and are relatively low through age 95 when they begin to climb again (95 = 9; 96 = 19; 97 = 27; 98 = 29; 99 = 42; 100–104 = 75).[56] These results are consistent with a recommendation of greater attention to driving behavior and "progressive licensing" in the younger age group, and the possibility of relicensing requirements for the oldest old drivers.



Age is also related to nonuse of seat belts among drivers in injury-present crashes. In the age group 15–24, 7.3 percent are classified as unbelted. The rate declines gradually with age to 5.5 percent for those age 40 and over.

Seat belt use varies somewhat by HRG crash site among drivers in crashes involving injury in 2003–2004. The Urban Centers (7.1 percent), Mill Towns (7.4 percent) and Rural Towns (7.5 percent) have nonuse rates significantly higher than the Manufacturing Centers (5.9 percent), Diverse Suburbs (5.5 percent) and Wealthy Suburbs (4.8 percent). To the extent that crash site and residence location are correlated, this may imply lower seat belt use rates for residents in the former three types of communities. This hypothesis can be checked only upon the possible future availability of the residential information in the DOT crash data.

YOUTH RISK BEHAVIOR SURVEY



Every odd year, DPH conducts a "Youth Risk Behavior Survey" (YRBS) based on items constructed by the Centers for Disease Control and Prevention (CDC) in cooperation with the states. The survey, called the Connecticut High School Survey, is distributed to a limited number of schools on a sampling basis. Results are shown in Figures 11 and 12.

FIGURE 11: CONNECTICUT HIGH SCHOOL SURVEY, POSITIVE (HEALTH-PROMOTING) BEHAVIOR PERCENTAGES, 2005

SEXUALLY TRANSMITTED DISEASES

Sexually transmitted diseases (STDs) are a good indicator of sexual risk-taking behavior (e.g., unprotected sex, having multiple sexual partners) in that they are reportable diseases and are eventually symptomatic. But sexual risk taking may have far different consequences in different contexts. Risk-taking behavior manifests itself in disease only in the context of a high incidence "pool" of disease. Thus, sexual risk taking in the Wealthy Suburbs is not as likely to manifest as disease as in the Urban Centers.

A possible reason for the STD rate differences demonstrated in Table 48 is differential reporting. This might occur if the large clinics in the Urban Centers report all cases while private physicians in the Wealthy Suburbs, for example, do not. Differential reporting would lead to differential rates and not recognize the underlying equality of disease rates. Although there are no data with which to test such a claim, it seems unlikely that this differential reporting could explain the observed rate differences. First, while persons from other communities may use the clinics in the Urban Centers, their cases are referred back to their towns of residence for rate calculation purposes. Reports also come in from STD testing labs as well as private physicians, meaning that unless the patient is treated without testing, and the physician does not report, a case will eventually be reported to DPH.

There would have to be a huge reporting differential to account for the large differences observed in Table 48, and for the race and ethnicity disparities noted within the HRGs. For example, such reporting differences could not account for the Asian/black difference in STD rates within the Urban Centers as shown in Table 49. Finally, these results are comparable to results in other states and nationally.[57]

TABLE 48: ANNUALIZED CRUDE CASE RATE OF SEXUALLY TRANSMITTED DISEASES PER 1,000 RESIDENTS, 2000-2004 AND CASES, 2005

AREA	Population	Annual Average Count, 2000-2004 and Count, 2005	Annual Average Rate per 1,000, 2000-2004	Percentage of Cases, 2000-2004
HRG 1 (3)-UC	384,733	4,970 (5,653)	21.5	42.2%
Bridgeport	139,529	1,437 (1,728)	17.2	12.2%
Hartford	121,578	2,147 (2,145)	29.4	18.2%
New Haven	123,626	1,387 (1,780)	18.7	11.8%
HRG 2 (10)-MC	662,398	3,016 (3,492)	7.6	25.6%
HRG 3 (15)-DS	587,509	1,617 (2,051)	4.6	13.7%
HRG 4 (27)-WS	487,620	235 (318)	0.8	2.0%

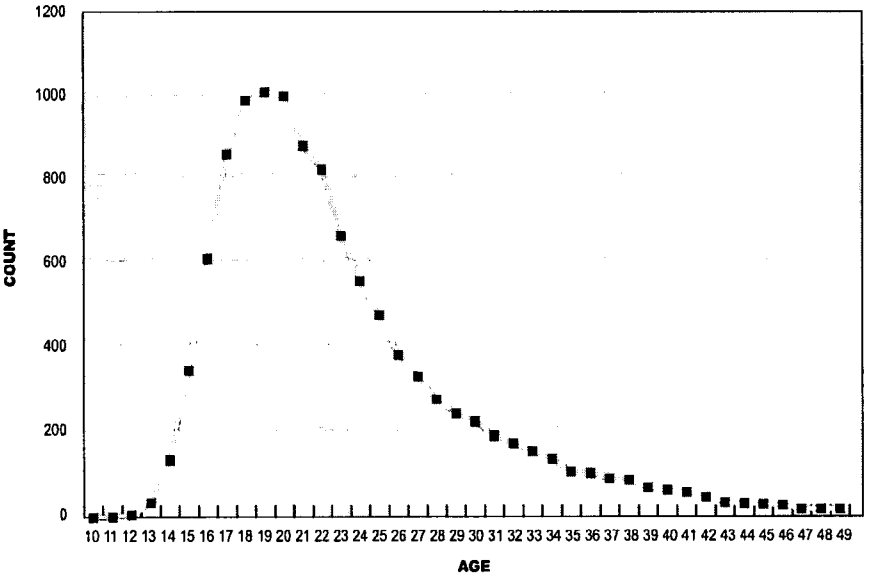
Unknown Residence		870 (761)		7.4%
Connecticut	3,405,565	11,782 (13,846)	5.8	100.0%

Source: DPH; U.S. Census 2000, SF1: Table P1.
Data note: These data are incident cases. Over the five-year period tabulated, a single individual may have many more than one case of an STD. Thus, the data should not be interpreted as the probability that a single individual will be infected.
Blank cells indicate that data were not available due to small survey numbers or otherwise not calculated or available.

Table 49 shows all cases for which race, ethnicity, HRG, and age could be ascertained in the age range 15 to 34.

TABLE 49: ANNUALIZED SEXUALLY TRANSMITTED DISEASE CASE RATE PER 1,000 FOR PERSONS 15 TO 34 YEARS OLD, 2000-2004

AREA	White, Not Hispanic	Black, Not Hispanic	Hispanic	Asian, Not Hispanic
HRG 1 (3)-UC	6.3	53.5	22.7	2.7
HRG 2 (10)-MC	3.3	29.7	11.1	1.6
HRG 3 (15)-DS	2.5	28.1	10.0	1.8
HRG 4 (27)-WS	0.6	9.0	3.7	0.4
HRG 5 (39)-MT	1.3	11.4	4.4	1.2
HRG 6 (75)-RT	1.0	6.9	3.3	2.1
Connecticut	2.2	39.3	15.1	1.9



Source: DPH; U.S. Census 2000.

These results demonstrate significant effects for both race/ethnicity and for HRGs. Whites, blacks and Hispanics residing in the Urban Centers have double the STD rates as in the Manufacturing Centers. The Manufacturing Centers' and Diverse Suburbs' rates are similar, and higher than rates in Wealthy Suburbs, Mill Towns and Rural Towns. Asians have the lowest STD rate, except in the Rural Towns, but the base numbers here are very small, and the difference is of doubtful significance. Blacks consistently have a higher STD rate than Hispanics, whites or Asians, and an extremely high rate in the Urban Centers.

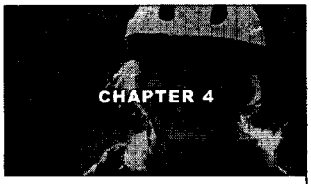
Recent data for 2005 indicate a modest increase from the average number of cases in 2000-2004. The increase appears in all HRGs and may not be accounted for by a reduction in the number of cases with unknown residence.

Residents between ages 15 and 34 account for 90.4 percent of all STD cases for which age could be ascertained. The modal age of incidence is 20 years old, as illustrated in Figure 13.

FIGURE 13: AVERAGE ANNUAL SEXUALLY TRANSMITTED DISEASE COUNTS, BY AGE, FOR PERSONS 10 TO 49 YEARS OLD, 2000-2004

Source: DPH.

HIV/AIDS



HIV/AIDS is an indicator related to STDs in some modes of transmission. Table 50 shows the number of adult AIDS cases, by gender and mode of transmission for 2006. These results indicate that men who have sex with men (MSM) predominate among white males. But for black and Hispanic males, the dominant mode of transmission is intravenous drug use (IDU). The mode of transmission for women also differs by race and ethnicity, as shown in Table 50.

The overall counts of AIDS cases declined for both men and women in 1998. For both groups AIDS counts have remained relatively constant since that time, at about 400 cases per year for adult men and about 200 cases per year for adult women, with some year-to-year variation for both genders. AIDS death rates have dropped markedly over the past decade, due in part to improved therapies. In 2006, approximately 50 percent of all AIDS cases were incident in the Urban Centers. An additional 25 percent of all AIDS cases were incident in the Manufacturing Centers.

TABLE 50: ADULT AIDS CASES IN CONNECTICUT, 2006

MODE OF TRANSMISSION	Race/Ethnicity	Adult Male	Adult Female
MSM	White	47	
	Black	16	
	Hispanic	27	
	Other	2	
IDU	White	31	19
	Black	28	12
	Hispanic	58	26
	Other	4	
MSM/IDU	White	2	
	Black	2	
	Hispanic	2	
	Other		
HETEROSEXUAL	White	3	16
	Black	12	23
	Hispanic	12	28
	Other	2	2
OTHER / UNKNOWN	White	23	10
	Black	27	19
	Hispanic	39	31
	Other	5	6

Data and Reference Note: HIV/AIDS data are continually updated, as case counts are de-duplicated, and as other new information, e.g., regarding transmission mode, becomes available, and data are reported from other states. Therefore, the counts reported here may be slightly different than those accessed from the DPH HIV/AIDS web site at another point in time. Access current data and historical series at: http://www.dph.state.ct.us/BCH/infectiousdise/2003/final%20page:/topic_index_X.htm.

TEEN BIRTHS

Teen childbearing is a serious problem with profound health, social and economic consequences. Infants of adolescent mothers are more likely to face adverse health outcomes, including low birth weight, preterm birth and infant mortality. Teen mothers are more likely to be unmarried, high school dropouts and living in poverty. Their children also are more likely to live in poverty years after birth.[58]

Table 51 illustrates that Connecticut's teen birth rate has fallen significantly between 1991 and 2002, as it has for the United States and all New England states.

TABLE 51: HISTORICAL CHANGE IN TEEN BIRTH RATE PER 1,000 TEENS AGES 15-19, 1991 TO 2002

STATE	1991	2002
CONNECTICUT	40.1	25.8
MASSACHUSETTS	37.5	23.3
RHODE ISLAND	44.7	35.6
MAINE	43.5	25.4
NEW HAMPSHIRE	33.1	20.0
VERMONT	39.2	24.2
UNITED STATES	61.8	42.9

Source: National Campaign to Prevent Teen Pregnancy, from data at CDC, National Center for Health Statistics. Web-based data accessed at: www.teenpregnancy.org, Sept. 16, 2005.

TABLE 52: ANNUALIZED TEEN (15-19) BIRTH RATE PER 1,000, BY RACE/ETHNICITY, 1999 TO 2003

RACE/ETHNICITY/ORIGIN	Teen Births	Teen Population	Rate per 1,000 Teens
All Races	12,644	105,336	24.0
White Not Hispanic	4,288	73,851	11.6
Black Not Hispanic	2,992	11,872	50.4
Asian Not Hispanic	269	2,731	19.7
Hispanic	4,969	13,918	71.4
Puerto Rican	3,946	9,303	84.8
Non-Puerto Rican Hispanic	1,023	4,615	44.3

Source: DPH; U.S. Census 2000.
Note: A small number (344) of births at ages younger than 15 were excluded from this table. Over half, 180 of these, were born to black non-Hispanic (79) and Puerto Rican Hispanic (101) teens. A small number of unknowns were also excluded from the table.

0483
09/15/08

There are clear disparities in teen birth rates in Connecticut. Analysis of the rates shown in Table 52 illustrates the dangers in the broad brush approach. While Hispanic teens have the highest birth rates, the aggregation of all Hispanics together obscures important variation. The non-Puerto Rican Hispanic teen rate (44.3 per 1,000) is only slightly more than half the Puerto Rican teen rate (84.8 per 1,000). Very young teens giving birth, under age 15, are overwhelmingly black and Puerto Rican girls. Thus, teen pregnancy prevention programs could prioritize the key populations at risk: Puerto Rican Hispanic teens, followed by black and non-Puerto Rican Hispanic teens.

There are very large HRG differences in teen births, even after controlling for race and ethnicity, as shown in Table 53. For each group, teen birth rates in the Urban and Manufacturing centers are higher than for the remaining HRGs. The Wealthy Suburbs show the lowest rate for each group, except for black non-Hispanic teens whose rates are lowest in the Rural Towns. Teen birth rates by HRG are, in decreasing order: Urban Centers > Manufacturing Centers > Diverse Suburbs > Mill Towns > Rural Towns > Wealthy Suburbs.

TABLE 53: TEEN (15-19) ANNUALIZED BIRTH RATE PER 1,000, BY RACE AND ETHNICITY, CONNECTICUT AND HRG, 1999-2003

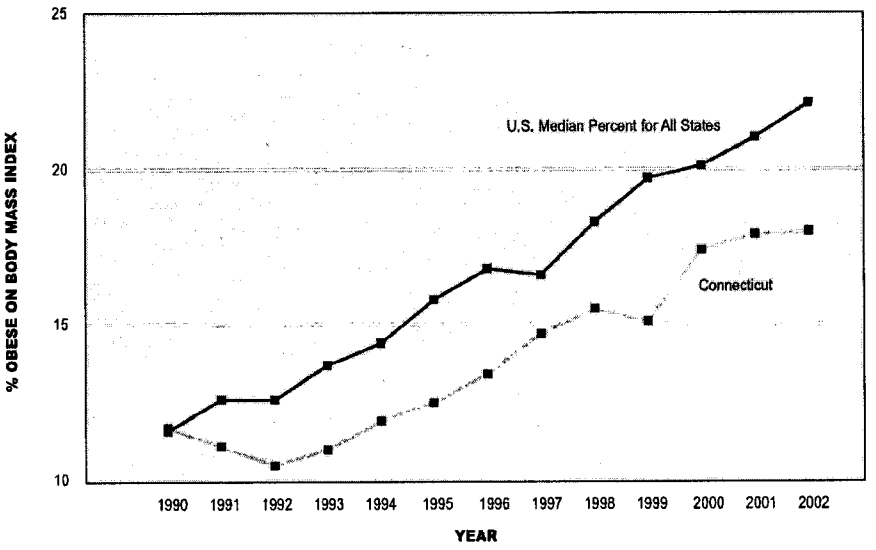
RACE/ETHNICITY/ ORIGIN	HRG 1 (3)-UC	HRG 2 (10)-MC	HRG 3 (15)-DS	HRG 4 (27)-WS	HRG 5 (39)-MT	HRG 6 (75)-RT	State
All Races	57.3	39.9	22.2	2.9	13.0	7.3	24.0
White Not Hispanic	19.8	20.4	16.2	2.3	12.3	6.9	11.6
Black Not Hispanic	61.7	45.9	41.4	11.0	24.8	9.5	50.4
Asian Not Hispanic	31.0	32.0	27.4	5.2	8.5	7.1	19.7
Hispanic	83.5	79.7	52.3	14.6	30.4	19.0	71.4
Puerto Rican	90.8	95.5	63.1	29.3*			84.8
Non-Puerto Rican	55.9	53.8	32.1	18.8*			44.3

Source: DPH; U.S. Census 2000, SF4:Table PCT5.

**Separate HRG estimates for Puerto Rican and non-Puerto Rican Hispanic populations for HRGs 4-6 are not available due to the suppression rules of the U.S. Census Bureau. Many cities and towns in these HRGs had no denominator data for calculating rates due to small total numbers (e.g., fewer than 100) of Puerto Rican residents.*

In summary, the disparities for teens are very large — in contrast to the data for women age 25 to 49 presented in Chapter 3, Connecticut Community Profile, showing only small "broad" race and ethnicity birth rate differences. Puerto Rican teens are especially at risk for teen birth in the Urban and Manufacturing centers.

RISK FACTORS FOR METABOLIC SYNDROME AND DIABETES



Poor diet and a lack of physical activity are responsible for a cluster of metabolic disorders — referred to as "metabolic syndrome" — including high blood pressure, high insulin levels, excess body weight, and abnormal levels of cholesterol. These disorders can cause such serious diseases as diabetes, heart disease and stroke. In combination, they dramatically boost a person's chances of premature mortality.

Overweight and Obesity

Overweight and obesity are defined by the body mass index (BMI), a ratio of body weight to height. An adult is overweight if s/he has a BMI of 25 to 29.9 (145 pounds for an adult 5'4") and obese if the BMI is 30 or higher (174 pounds for an adult 5'4").

Overweight and obesity are risk factors for a wide range of chronic diseases, including diabetes, hypertension, heart disease, gall bladder disease, and osteoarthritis.[59] The federal government's *Healthy People 2010* objective is to reduce the level of obesity among Americans to 15 percent or less.[60] But the percentage of adults who are overweight and obese has increased in recent years — making obesity a leading public health issue.

FIGURE 14: PERCENTAGE OBESE, CONNECTICUT AND UNITED STATES, 18 AND OLDER

Source: CDC BRFSS web site at: http://www.cdc.gov/brfss.

0485
09/15/08

As of 2000, more than 53 percent of Connecticut adults were overweight and more than 17 percent were obese. There were marked differences among the HRGs in the percentage of overweight and obese adults, as presented in Table 54. The Urban Centers had more than twice the percentage of obese adults as the Wealthy Suburbs. There were also differences in overweight and obesity by city. Bridgeport had a particularly high percentage of overweight and obese adults: More than two-thirds of Bridgeport adult residents were overweight and one-quarter of them obese.

In Connecticut overall, overweight and obesity were highest among black and Hispanic residents. Although there was a higher prevalence of overweight and obesity among black adults in all HRGs (when sufficient data was available), the prevalence among Hispanics in the Diverse Suburbs, Mill Towns and Rural Towns was similar to that of whites. Asian adults have by far the lowest rates of obesity, and their rates do not vary significantly by type of community.

TABLE 54: PERCENTAGE OBESE BY BODY MASS INDEX (BMI)

AREA	All Race and Ethnicity, Crude Percentage	All Race and Ethnicity, Age-Adjusted Percentage	White, Not Hispanic	Black, Not Hispanic	Hispanic	Asian, Not Hispanic

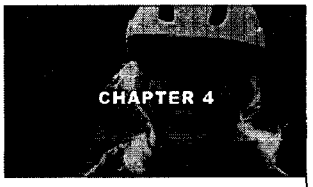

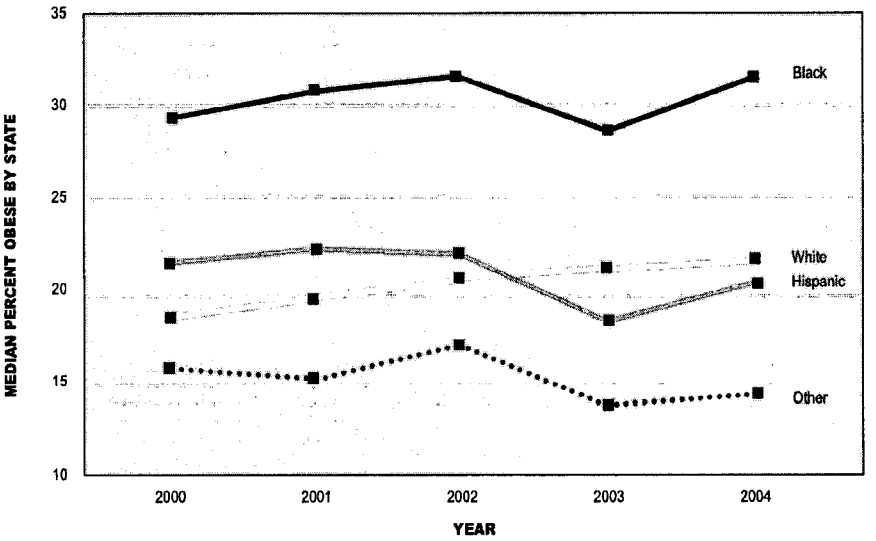

FIGURE 15: OBESITY BY RACE AND ETHNICITY: NATIONAL TRENDS

Source: CDC BRFSS web site at: http://www.cdc.gov/brfss.

There are no readily available longtime trend data on obesity by race and ethnicity. The available series of national medians' by year, shown in Figure 15, suggests that increases in obesity among whites over a period of five years have driven the increasing national levels of obesity. The lowest levels are in the "other" category, which includes Asians and all other groups, followed by whites and Hispanics.

Black residents show the highest percentage of obesity among those groups reported in the Behavioral Risk Factor Surveillance System (BRFSS) survey, 1999-2003. Within this group there are significant age and gender disparities such that black women have a higher percentage obese than black men in age group 18-29 (23.9:20.3 percent), 30-44 (36.1:27.4 percent), 45-59 (41.6:31.9 percent), and 60 and over (36.3:23.8 percent). The male-female differences are statistically significant except in the youngest age group. These results have significant implications for long-term health outcomes. No systematic data are available on environmental factors such as access to healthy foods and exercise venues. Also, there is no systematic data about cultural factors such as attitudes towards diet and exercise or ideal body type available to explain these age/gender trends and the broader race/ethnicity disparities reported here.

High Blood Pressure and High Blood Cholesterol

Both high blood pressure and high cholesterol are closely related to cardiovascular disease. The higher the blood pressure, the greater the chance of heart attack, heart failure, stroke, and kidney disease.[61] High levels of blood cholesterol, particularly low-density lipoprotein (LDL) cholesterol, increases the build up of cholesterol in the arteries and may block blood flow, leading to heart disease.[62]

0487
09/15/08

Thirty-one percent (crude rate) of Connecticut adults self-reported high blood pressure, and 29 percent reported high cholesterol. The Wealthy Suburbs had the lowest prevalence of both high blood pressure and high cholesterol. The other HRGs did not vary much in prevalence of high blood pressure and cholesterol, and there were no significant differences between the cities of the Urban Centers.

A higher percentage of Connecticut black adults than white adults reported high blood pressure, as shown in Table 55. This pattern was also seen within the Urban and Manufacturing centers and the Diverse Suburbs. Although there were no differences for the state overall in reported high cholesterol by race/ethnicity, the percentage of Hispanics in the Diverse Suburbs reporting high cholesterol was lower than that reported by whites and blacks, as seen in Table 56.

The federal government's *Healthy People 2010* objectives are to reduce the rates of American adults with high blood pressure to 16 percent and those with high cholesterol to 14 percent.[63] For each of these indicators, Connecticut residents in all HRGs are far above the national objectives.

Physical Activity and Diet

Physical activity has been shown to reduce levels of obesity and improve cardiovascular health.

Table 57 and Table 58 show significant differences in levels of physical activity by HRG and race/ethnicity. There are only limited data for Connecticut on diet, another important indicator, as shown in Table 59. Black and Hispanic adults are far more likely than white adults to report no physical activity and less likely to report regular exercise. Asian adults are least likely to report consuming "five or fewer" fruits and vegetables per day as shown in Table 59, indicating a possibly healthier diet.

DRUG USE AND ABUSE: SMOKING AND ALCOHOL

According to a study published in the Journal of the American Medical Association (JAMA) about the causes of death in the United States, alcohol abuse has been associated with 60 percent to 90 percent of cirrhosis deaths; 40 percent to 50 percent of motor vehicle fatalities; 16 percent to 67 percent of home injuries, drowning, fire fatalities, and job injuries; and 3 percent to 5 percent of cancer deaths.[64]

Alcohol abuse is responsible for even more harm as it is implicated in child and intimate partner abuse; homicide; and loss of employment, family and community connection.

Findings and Analysis

Problem drinking, especially binge drinking (having five or more drinks on an occasion), is in many respects a "white" youth and young adult cultural problem. Among Connecticut adults 18 and over, 17.5 percent of whites report binge drinking, while this is true for only 9.0 percent of blacks, 14.5 percent of Hispanics and 8.2 percent of Asians. There are highly significant differences between whites and Hispanics on the one hand, and blacks and Asians on the other hand — and they are the same in every HRG for which comparative data are available. The problem is both statewide and nationwide.

TABLE 60: PERCENTAGE WHO ENGAGED IN CHRONIC (HEAVY) DRINKING IN PAST MONTH

Note: All race and ethnicity specific rates are age-adjusted.
Blank cells indicate that data were not available due to small survey numbers or otherwise not calculated or available.

The data in Figure 16 suggest that white binge drinking is particularly prevalent among 18- to 34-year-olds. By age 44, the Hispanic binge drinking rate is equal to the white rate and by age 54, the black binge drinking rate is equal to the white rate. There are no statistically significant differences among race/ethnicity groups after age 55, as all fall to a comparatively low level.

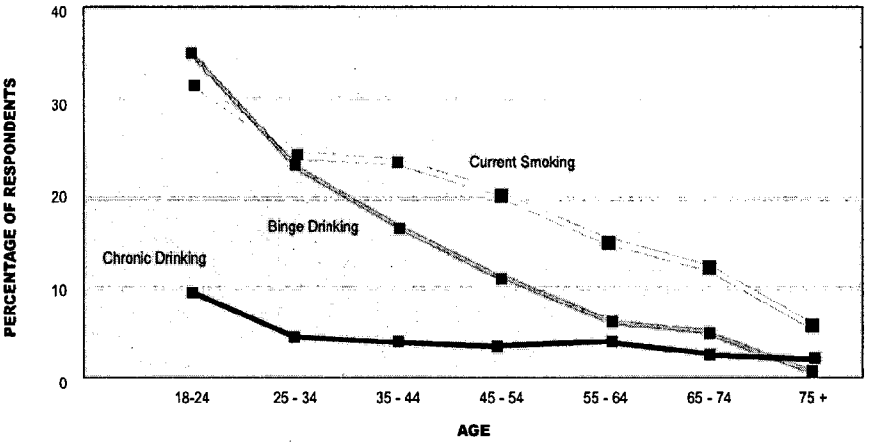

FIGURE 16: PERCENTAGE BINGE DRINKING BY AGE AND RACE/ETHNICITY, BRFSS, 1999-2003

Source: DPH BRFSS Survey Data, 1999-2003.

The disparities in rates for chronic drinking — more than two drinks on the average day for men; more than one drink per day for women — parallel the rates for binge drinking. Five percent of whites report chronic drinking, as compared with 1.9 percent of blacks, 3.6 percent of Hispanics and 1.4 percent of Asians. As illustrated in Figure 17, smoking and binge drinking are clearly related to age, while chronic drinking is not, except for a slightly higher rate in the youngest age group (18 to 24 years old).

FIGURE 17: PERCENTAGES REPORTING CURRENT SMOKING, BINGE AND HEAVY (CHRONIC) DRINKING, BRFSS,1999-2003

Source: DPH BRFSS Survey Data, 1999-2003.

Drinking and smoking "go together" in the sense that those who smoke are also more likely to abuse alcohol. As illustrated in Table 62, the "relative risk" ratio — the association between binge drinking and smoking — is significantly elevated above 1 for every category of educational attainment. This relationship is most pronounced for those at the lowest level of educational attainment.

TABLE 62: PERCENTAGE REPORTING CURRENT SMOKING AND BINGE DRINKING FOR CONNECTICUT RESIDENTS 25 AND OVER, BY EDUCATIONAL ATTAINMENT, 1999-2003

EDUCATION	Current Smoking	Binge Drinking	Both	Relative Risk*
LESS THAN HIGH SCHOOL GRADUATE	27.1	10.1	5.7	4.2
HIGH SCHOOL GRADUATE	26.5	13.6	6.1	2.7
1-3 YEARS COLLEGE	22.0	12.4	4.4	2.2
COLLEGE GRADUATE OR MORE	10.8	13.5	3.1	3.1

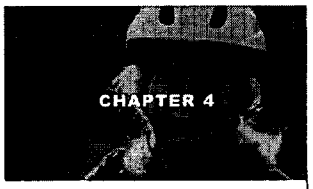
Source: DPH BRFSS Survey Data, 1999-2003.

**Table includes only those age 25 and older who answered all three questions: Educational Attainment, Current Smoking and Binge Drinking. Relative Risk would be 1 if there was no association between smoking and binge drinking.*

Note: All race and ethnicity specific rates are age-adjusted.

Advanced educational level (college graduate or more) is a strong independent predictor of reduced smoking but not of binge drinking (five or more drinks on one occasion in the past month). College graduates are least likely to be current smokers (10.8 percent), but they are not less likely to be binge drinkers (13.5 percent). There is a strong association for persons age 25 and over between binge drinking and smoking, regardless of educational level.

Smoking



Tobacco use is the leading cause of premature death in the United States. A JAMA article about the causes of death in the United States implicated tobacco use in 19 percent of all deaths nationally. "It contributes substantially to deaths from cancer (especially cancers of the lung; esophagus; oral cavity; pancreas; kidney; and bladder; and perhaps of other organs), cardiovascular disease (coronary artery disease, stroke, and high blood pressure), lung disease (chronic obstructive pulmonary disease and pneumonia), low birth weight; and other problems of infancy and burns."[65]

As shown in Table 63, the age-adjusted rate of 20.9 percent smokers among Connecticut adults 18 years old and older is far above the *Healthy People 2010* target of 12 percent current smokers. Whites, blacks and Hispanics do not differ significantly (21.3 percent of whites, 20.9 percent of blacks and 20.6 percent of Hispanics are smokers), but they are far more likely than Asians (7.4 percent) to be smokers.

TABLE 63: PERCENTAGE CURRENTLY SMOKING

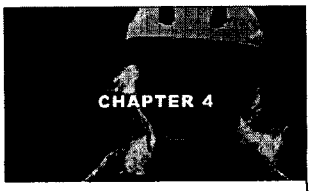
Although the overall smoking rates for whites, blacks and Hispanics are not different, the age patterns are somewhat different. Whites between 18 and 24 years old show a significantly higher rate but then trend consistently downward by age. Black and Hispanic respondents show a different pattern: lower rates of smoking in the youngest age group, but no consistent downward age trend over the middle years. Black respondents who smoke continue smoking until relatively late in life. What is not currently known is whether these different patterns are due to older age at initiation, greater degree of addiction due to type of cigarette smoked or depth of inhalation, as some researchers have suggested,[66,67] or to differential targeting or effects of smoking promotion or cessation messages in these groups.

FIGURE 18: PERCENTAGE SMOKING BY AGE AND RACE/ETHNICITY, BRFSS, 1999-2003

Source: DPH BRFSS Survey Data, 1999-2003.

Singh and Miller,[68] Diamond,[69] and others have demonstrated that formerly healthy immigrants suffer from prolonged exposure to American culture. Immigrants, particularly black and Hispanic immigrants, succumb to alcohol abuse and tobacco use with many negative consequences.[70]



Environmental Tobacco Smoke

Many studies have shown that environmental tobacco smoke (ETS), sometimes known as "secondhand smoke," affects the health of nonsmokers. ETS can cause developmental effects such as low birth weight and Sudden Infant Death Syndrome (SIDS); respiratory effects such as bronchitis, pneumonia, new or exacerbated asthma, and chronic respiratory symptoms and middle ear infections in children; eye and nasal irritation; lung cancer; nasal sinus cancer; heart disease mortality; and acute and chronic coronary heart disease morbidity in adults.[71]

One goal of the *Healthy People 2010* initiative is the establishment of smoke-free places such as school facilities, property, vehicles, and school events; private and public workplaces; restaurants; public transportation; day care centers; and retail stores.[72]

Connecticut's smoke-free law went into effect on Oct. 1, 2003, and expanded to bars in April 2004. But some businesses (e.g., those with fewer than five employees) have weaker coverage, and they rely on employee complaint to instigate change. A weakness in the law is that no agency has been charged with enforcement. There have also been no systematic studies of compliance. Some workers, such as nurses who escort psychiatric or nursing home patients outside to smoke, are at risk — and apparently not well protected in practice. The law also does not address the effects of ETS in apartment and condominium living situations.[73]

In summary, there are no Connecticut data to assess compliance with regulations related to ETS or exposures to it.

CHAPTER 5

ACCESS TO CARE

Several factors affect access to and use of health care in Connecticut, including:

- Health insurance status
- "Safety net" programs
- Availability of health care facilities and professionals
- Language compatibility between health care providers and residents
- Adequacy of prenatal care
- Access to community water fluoridation

HEALTH INSURANCE STATUS

Persons with no health insurance are less likely to have a regular source of health care or to receive preventive care, and experience worse health outcomes as compared to those with health insurance.[74] Having a regular health care provider is an important indicator as it increases use of ambulatory visits, prompt care when sick, and receipt of preventive health care.[75] The *Healthy People 2010* initiative aims for a goal of no adults under age 65 without health insurance, and 96 percent with a source of ongoing health care.[76]

The most current statistics on health insurance coverage are generated by the Current Population Survey of the U.S. Census Bureau. This survey documents a small but statistically significant annual increase in the percentage of U.S. residents who lack health insurance — defined as any type of insurance, public or private — 14.6 percent uninsured in 2001, 15.2 in 2002, 15.6 percent in 2003 and 2004, and 15.9 percent in 2005.

Connecticut remained essentially constant at 10.4 percent and 10.5 percent for the time periods 2001-2002 and 2002-2003, but increased in 2003-2004 to 11.0 percent uninsured. For the three-year average 2003-2005 Connecticut as a state ranks 11th in coverage, behind all other New England states. The uninsured rate nationally, in 2005, was 11.3 percent for white-alone non-Hispanic; 19.6 percent for black-alone non-Hispanic; 17.9 percent for Asian; and 32.7 percent for Hispanic (any race) residents.[77]

According to self-reports in the Behavioral Risk Factor Surveillance System (BRFSS) surveys, conducted between 1999 and 2003, almost 12 percent of Connecticut residents between the ages of 18 and 64 claimed that they did not have health insurance. Eighty-six percent of Connecticut residents age 18 and over reported having a regular source of medical care — a "medical home" — and 76 percent received a checkup in the past year during the time period 1999-2003. There were marked differences in access to care by HRG. Residents in the Urban and Manufacturing centers were less likely to have health insurance and less likely to have a regular source of care. However, they were not less likely to have had a checkup in the past year as compared with residents in other HRGs. Among the Urban Centers, a higher proportion of Hartford and Bridgeport residents reported having no health insurance than residents of New Haven, as shown in Table 64.

Hispanic and black adults were more likely than white adults to have no health insurance and less likely to have a regular source of medical care than white adults, as shown in Table 65. But the data indicate, paradoxically, that black adults were more likely to have had a checkup in the past year, as shown in Table 66.[1] These latter disparities were present within all HRGs. While Asians were no less likely than whites to have health insurance, they were less likely to report a regular source of medical care.

DENTAL VISITS

Oral health is an essential component of overall health status. Poor oral health and untreated oral diseases, such as dental caries and periodontal diseases, can negatively affect quality of life and lead to more serious infections. Regular dental care is an important component of oral health. Many persons do not receive preventive dental services because of lack of insurance or fear of dental visits.[78]

Overall, 79 percent of Connecticut adults reported visiting a dentist in the past year. The Wealthy Suburbs and Rural Towns had the highest percentages of residents reporting a recent dental visit, and the Urban and Manufacturing centers had the lowest percentages, as seen in Table 67.

In all HRGs where there were sufficient sample sizes to make a determination, Hispanic and black adults were less likely than white adults to have had a recent dental visit.

TABLE 67: PERCENTAGE WITH DENTAL VISIT IN PAST YEAR

AREA	All Race and Ethnicity, Crude Rate	All Race and Ethnicity, Age-Adjusted Rate	White, Not Hispanic	Black, Not Hispanic	Hispanic	Asian, Not Hispanic
Bridgeport	63.3	64.7	65.3

SAFETY NET: NEEDY INDIVIDUALS AND FAMILIES IN CONNECTICUT

Connecticut Department of Social Services

The Connecticut Department of Social Services (DSS) provides assistance to needy families and individuals to facilitate their access to needed medical care and help maximize their overall health. DSS tracks utilization of five major assistance programs by monthly caseload units and recipients. These DSS-tracked assistance programs are represented in Table 68 and Table 69. Appendix E includes a brief description of each of the five programs.

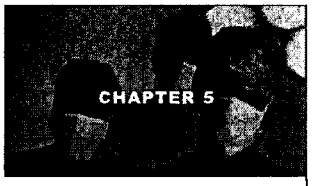

TABLE 68: AVERAGE MONTHLY CASES AND PERSONS ON FOOD STAMPS, TEMPORARY FAMILY ASSISTANCE AND STATE SUPPLEMENT (STATE FISCAL YEAR 2005)

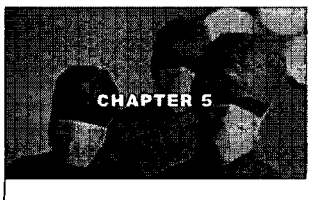

AREA	Food Stamps		Temporary Family Assistance - Totals		State Supplement			
	Cases	Persons	Cases	Persons	Aged	Blind	Disabled	Total

Connecticut	99,160	188,591	22,073	48,174	5,028	93	11,370	16,492

Source: DSS, Central Office, Information Technology Services, Electronic file. E-mail communication from S. Colangelo. Sept. 25, 2006.
Note: The following program categories are not shown in the DSS tables: Refugee, Refugee Medical, State Funded Medical, and Connecticut AIDS Drug Assistance Program (CADAP). Statewide totals may not equal sums due to rounding. Due to rounding some towns may not display a case but will display recipients. This is due to most cases having more than one recipient and therefore when averaged, the recipient count will be .5 or higher, and be counted as 1. State Supplement is a state-financed cash assistance program to supplement the income of the aged, blind and disabled that have another source of income such as disability benefits or Supplemental Security Income (SSI).

** Total Medicaid counts exclude Qualified Medicare Beneficiary (QMB) and Specified Low Income Medicare Beneficiary (SLMB) cases due to program overlap.*
The following program categories are not shown in the DSS tables: Refugee, Refugee Medical, State Funded Medical, and CADAP. State totals may not equal sums of HRGs due to rounding.

PROGRAMS FOR CHILDREN AND ADOLESCENTS

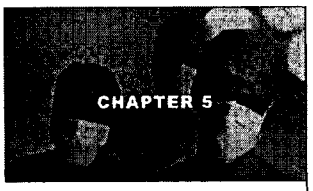
The state departments of Social Services (DSS) and Children and Families (DCF) provide health-promoting services to needy Connecticut youth, including:

- Health care services
- Child protective services (including telephone hotline) to process reports of child abuse and neglect
- Youth emergency assessment and respite services (YEARS), including emergency youth shelters
- Substance abuse and mental health services
- Youth safe homes
- Foster and adoption services
- Health care and residential treatment facilities

Below are brief descriptions of selected services and data on availability and utilization.

Healthcare for UninSured Kids and Youth (HUSKY)

The HUSKY program provides health care services for Connecticut's younger residents via coverage for preventive care, outpatient and in-hospital care, prescription drug coverage, and mental health/substance abuse services. The HUSKY A program, for children in households at or below 100 percent of the federal poverty level (FPL), had an enrollment of 304,633 during fiscal year 2004. The HUSKY-B program, for youth under age 19 in certain households with higher incomes enrolled 14,533 youth in fiscal 2004.[79]



Youth Emergency Assessment and Respite Services (YEARS)

The YEARS program makes available 101 beds in eight affiliated shelters to 11- to 17-year-old children who are in crisis due to abuse, neglect or abandonment. The eight YEARS-affiliated youth shelters are listed by HRG in Appendix G. Other youth emergency shelters operate within the state of Connecticut but are not officially affiliated with the YEARS program.

TABLE 70: CHILDREN SERVED BY YEARS PROGRAM: SNAPSHOT, JULY-SEPTEMBER 2004

AGE	PERCENTAGE	GENDER	PERCENTAGE	RACE/ETHNICITY	PERCENTAGE
< 5	2.2	Male	44.2	African American/Black	35.0
5-7	1.8	Female	55.8	Caucasian/White	31.4
8-12	11.9			Puerto Rican	25.2
13-17	84.1			Biracial	2.2
				Central American	1.8
				Other Spanish Speaking	1.8
				West Indies/Islander	1.3
				Other	0.9
				South American	0.4

Source: DCF YEARS: Statistical Report, Performance-Based Contracting state fiscal year 2005 (Date Range: July 1, 2004 to Sept. 30, 2004).

During an assessment period between July and September 2004, the YEARS program served 226 youth. Of these, 57.6 percent stayed in the YEARS shelter for 45 days or less, while 42.4 percent stayed longer than 45 days. The demographic data in Table 70 reflects the 226 children served by the YEARS program in the 2004 assessment period.[80]

Other Youth Placement Services

DCF offers other treatment and placement services to needy children and adolescents besides the shelters affiliated with the YEARS program. DCF's Child Protective Services Division investigates reports of child maltreatment and arranges necessary follow-up. This can include in-home services to children and families or placement of children in temporary or permanent locations outside the home.

Child Protective Services' 2004 caseload included 18,227 cases. A needs assessment was conducted based upon a random, representative sample of 375 cases. DCF found an over-representation of black and Hispanic families in the Child Protective Services caseload. Black children also were removed from their homes as a result of Child Protective Services investigation at a higher rate than children from other race and ethnicity groups.

TABLE 71: SAMPLE CASELOAD FROM CONNECTICUT CHILD PROTECTIVE SERVICES BY RACE/ETHNICITY AND SERVICE PROVIDED, 2004

RACE/ETHNICITY	In-Home Services	Removal From Home
WHITE	26%	22%
HISPANIC	22%	24%
BLACK/AFRICAN AMERICAN	26%	34.5%
UNABLE TO DETERMINE/UNKNOWN	22%	14%
MULTI	3%	5%
OTHER (ASIAN, AMERICAN INDIAN, ALASKAN NATIVE, NATIVE HAWAIIAN, OTHER PACIFIC ISLANDER)	<1 %	.5%

Cases are children under 18 or under 21 and clients of DCF

Preventive Oral Health Care for Children in HUSKY A

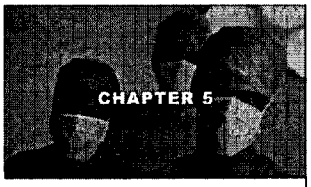
Oral health data are available from DSS for children ages 3 to 19 who were continuously enrolled during fiscal years 2000-2002 and during calendar years 2003-2005. In 2003, 140,728 children were continuously enrolled in HUSKY A; in 2004 there were 146,598, and in 2005 there were 146,046. There were virtually no changes in either oral preventive care (40 percent for 2003 and 2004, and 41 percent for 2005) or treatment (21 percent in 2003 and 2004, and 22 percent in 2005).

The preventive oral health care rate was highest for Hispanic children ages 3 to 19 (43 percent in 2004 and 45 percent in 2005), next for white (39 percent in both years) and black (38 percent in 2004 and 39 percent in 2005) children and youth. The percentage was highest in Hartford (47 percent in 2004, 48 percent in 2005) followed by Bridgeport (40 percent in both years). There was a statistically significant increase in New Haven (35 percent in 2004 and 43 percent in 2005).[81]

Connecticut Pharmaceutical Assistance Contract to the Elderly and Disabled (ConnPACE)

DSS provides multiple health-promoting programs to needy elders in the state. ConnPACE helps elderly and disabled residents finance the cost of prescription medications. Monthly enrollment in ConnPACE averaged 51,000 in fiscal year 2004, 10.8 percent of the state population over age 65 (470,183 according to U.S. Census 2000). The DSS's Older Americans Act Program served 57,830 elders and their caregivers in fiscal year 2004 via home-delivered and group-setting meals, transportation, homemaker services, and adult day care.[82]

Nursing Home Care



Connecticut has 246 Medicare/Medicaid-certified nursing homes, accounting for 29,927 beds. These are distributed as in Table 72.

TABLE 72: MEDICARE/MEDICAID-CERTIFIED LICENSED NURSING HOMES, 2005

AREA	Number of Licensed Nursing Home Facilities	Number of Available Beds	Beds Per 1,000 Residents Age 80 and Over
HRG 1 (3)-UC	18	2,793	231.8
Bridgeport	5	910	
Hartford	5	832	
New Haven	8	1,051	
HRG 2 (10)-MC	50	5,939	220.6
HRG 3 (15)-DS	48	6,279	214.6
HRG 4 (27)-WS	30	3,861	207.4
HRG 5 (39)-MT	64	7,690	250.7
HRG 6 (75)-RT	36	3,365	168.2
Connecticut	246	29,927	217.6

Source: Centers for Medicare and Medicaid Services (CMS): Nursing Home Compare. Available at: http://www.medicare.gov/NHCompare.
Blank cells indicate that data were not available due to small survey numbers or otherwise not calculated or available.

The number and rate of nursing home beds is relatively large in the Mill Towns but much smaller in the Rural Towns. It seems likely that the Mill Towns, which are situated in relatively rural areas, provide a "catchment" to which elders from surrounding Rural Towns move for nursing home care.

INDIVIDUAL HEALTH CARE PROVIDERS

DPH tracks the status of service providers statewide via its Office of Licensure and Renewal. Table 73 shows the health-related service providers licensed at the end of calendar year 2004.

TABLE 73: CONNECTICUT LICENSED HEALTH CARE PROVIDERS, YEAR END, 2004

PROVIDER	COUNT
Physician/Surgeon	14,721
Physician Assistant	1,233
Licensed Practical Nurse	11,526

HRG 6 (75)-RT	584,847	1,713	2.9	484	0.8
Connecticut	3,405,565	11,402	3.3	2,744	0.8

Source: DPH, Licensure File, generated Aug. 16, 2005, and U.S. Census 2000, Table P1.

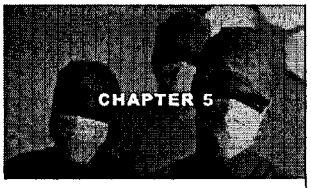
**Includes addresses as given in licensure file. No claims are made as to whether these are home or business addresses. All out-of-state addresses are deleted from the file, although some may practice in Connecticut. Some residents may go out of state for care.*

Doctors and dentists are not evenly distributed among the different types of communities, as shown in Table 74. While it is unclear whether licensees use their home or office addresses — there is likely a mixture of practice in this regard — it appears that the Urban Centers and the Wealthy Suburbs are relatively advantaged. Yet, the high rate for the Urban Centers is due to Hartford and, especially, New Haven, home of a large medical teaching hospital. Bridgeport, on the other hand, is very much disadvantaged, with only 1.6 physicians per 1,000 residents. The Mill Towns also have a low rate: 1.8 doctors per 1,000 residents.

With the exception of the Wealthy Suburbs, the distribution of dental practitioners is much more even across the HRGs, with a rate of 1.2 dentists per 1,000 residents. The Urban Centers have only 0.5 dentists per 1,000 residents.

LINGUISTIC ISOLATION

Language mismatches between patients and health care professionals can impede effective care. Language is indexed in the U.S. Census Bureau by household "linguistic isolation" — defined as households in which all members 14 and over have at least some difficulty with English. Linguistic isolation is shown in Table 23. The figure for Spanish-language household linguistic isolation is 7.8 percent of all households in the Urban Centers and 4.2 percent in the Manufacturing Centers. For all other HRGs, Spanish-language linguistic isolation is negligible. In the Urban Centers 3.3 percent of "Other Indo-European language" households are linguistically isolated, while in the Manufacturing Centers 3.4 percent of "Other Indo-European language" households experience linguistic isolation. In general, Asian-language linguistic isolation is negligible. There is no readily available means to track the availability of medical professionals who share language with those persons living in linguistically isolated households, since medical licensing bodies do not track language proficiency.



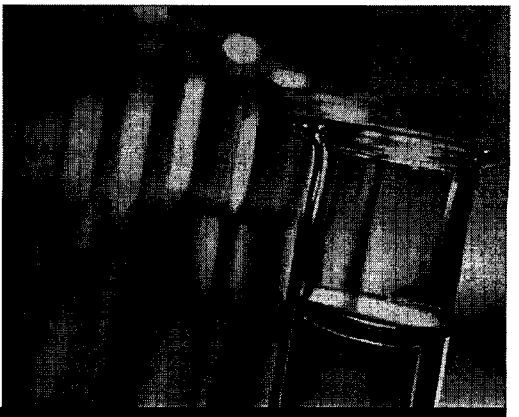
PRENATAL CARE

Prenatal care is another indicator of access to the "preventive" health care system. While the causal connections are complex, it appears that adequate prenatal care may assist in improving the health status and future reproductive health of mothers. There appears to be significant variation in access to and the timing of this care, as indicated in Table 75.

TABLE 75: PERCENTAGE OF BIRTHS WITH INADEQUATE, LATE OR NO PRENATAL CARE, 1999-2003

AREA	Total Population	White, Not Hispanic	Black, Not Hispanic	Hispanic	Puerto Rican	Hispanic, Non Puerto Rican	Asian
HRG 1 (3)-UC	37.0	29.0	34.1	43.5	39.8	54.4	
HRG 2 (10)-MC	31.1	21.4	39.0	44.5	43.7	45.5	
HRG 3 (15)-DS	22.5	19.5	29.1	32.6	32.3	32.9	
HRG 4 (27)-WS	11.8	11.4	22.7	24.9			
HRG 5 (39)-MT	19.9	18.6	29.8	33.7	24.6	31.9	
HRG 6 (75)-RT	17.5	16.8	31.8	25.4			
Connecticut	24.0	18.0	34.3	41.4	39.6	44.2	

Source: DPH, Vital Statistics.
Blank cells indicate that data were not available due to small survey numbers or otherwise not calculated or available.



In general, non-Puerto Rican Hispanics have the highest rates of inadequate, late or no care. It may be that these are immigrants who are not well attached to the health care system, or they are very recent immigrants without early prenatal care in their home countries. Next are Puerto Rican Hispanics, followed by black non-Hispanics and white non-Hispanics. No data were available for Asians.

ACCESS TO COMMUNITY WATER FLUORIDATION

DPH has promoted and documented the benefits of water fluoridation as reducing tooth decay by 20 percent to 40 percent.[83]

Connecticut's Public Water Supplies (PWS) provide optimally fluoridated drinking water to an estimated 70 percent of the total population or 2.39 million state residents. The state requires those serving at least 20,000 people to fluoridate their water to a level of 0.8 mg/1 and 1.2 mg/1, with a level of 1.0 mg/1 considered to be most beneficial to oral health. Twenty-five PWSs serving a total of 2.18 million residents are required to fluoridate their water. Eight PWS's serving 90,364 voluntarily fluoridate their water to benefit their customers. Thirty-five PWSs serving 110,715 residents purchase fluoridated drinking water from other utilities. Thirty PWSs provide naturally fluoridated water to approximately 5,300 residents.[84]

The extent of community water fluoridation in Connecticut is mapped in Appendix H.

CHAPTER 6

SCREENING AND PREVENTION

Screening and prevention are closely related to health care access. They are critical aspects of a high quality health system, since they may prevent disease or alter the course of disease and prevent early mortality.

SCREENING TESTS

Breast Cancer Screening

Breast cancer is the most common form of cancer among women, and the second leading cause of cancer-related death among women. Regular screening increases the likelihood of early detection, treatment initiation and positive outcome. The American Cancer Society recommends annual mammograms for women 40 and over.[85] The federal *Healthy People 2010* initiative aims for at least 70 percent of women age 40 and older to have received a mammogram within the preceding two years.[86]

TABLE 76: PERCENTAGE WITH A MAMMOGRAM IN PAST TWO YEARS, WOMEN 40 AND OVER

AREA	All Race and Ethnicity, Crude Percentage	All Race and Ethnicity, Age-Adjusted Percentage	White, Not Hispanic	Black, Not Hispanic	Hispanic	Asian, Not Hispanic
HRG 1 (3)-UC	81.7	82.1	83.0	77.0	81.9	
Bridgeport	82.5	83.1	85.4			
Hartford	82.6	83.2	82.6			
New Haven	79.9	79.7	81.7			
HRG 2 (10)-MC	80.6	81.9	81.3	80.8		
HRG 3 (15)-DS	81.2	82.1	81.9			
HRG 4 (27)-WS	84.2	84.9	85.2			
HRG 5 (39)-MT	80.9	80.8	81.5			
HRG 6 (75)-RT	84.4	84.5	84.1			
Connecticut	82.3	82.8	83.0	78.5	81.4	
United States	71.1	71.1	74.7	76.2	72.3	

Source: Behavioral Risk Factor Surveillance System (BRFSS) Survey Data, 1999-2003; Connecticut Department of Public Health (DPH); Centers for Disease Control and Prevention (CDC) BRFSS web site at: www.cdc.gov/brfss.
Note: All race and ethnicity specific rates are age-adjusted.
Blank cells indicate that data were not available due to small survey numbers or otherwise not calculated or available.

Nearly 83 percent of Connecticut women age 40 and older received a mammogram within the past two years, a higher rate than the U.S. population overall and the *Healthy People 2010* objectives. Recent mammogram testing was fairly consistent across HRGs and the large Connecticut cities, as shown in Table 76.

Although the percentage of black women in Connecticut who received a recent mammogram appears lower than that of white women, the sample size was too small to detect statistically significant differences or to examine race/ethnicity differences in mammogram tests among the HRGs or the Urban Centers' cities.

Cervical Cancer Screening

The American Cancer Society estimates that more than 10,000 women in the United States will be diagnosed with cervical cancer annually. Cervical cancer is curable if detected early. The Papanicolaou (Pap) smear test is a simple, routine screening that can detect early-stage disease and precancerous cells. It can be performed in a doctor's office as part of a routine gynecological exam. The American Cancer Society guidelines prescribe regular Pap smear tests for adult women.[87] The *Healthy People 2010* target is for at least 90 percent of adult women to have received a Pap smear within the past three years.[88]

Almost 88 percent of women in Connecticut received a Pap smear within the past three years, as shown in Table 77. The percentage varied somewhat by HRG, highest in the Wealthy Suburbs and the Rural Towns, lowest in the Urban Centers. Of the three Connecticut cities examined, the Pap smear test rate was lowest in Hartford and highest in New Haven.

TABLE 77: PERCENTAGE OF WOMEN WHO HAVE HAD A PAP SMEAR IN PAST THREE YEARS

AREA	All Race and Ethnicity, Crude Percentage	All Race and Ethnicity, Age-Adjusted Percentage	White, Not Hispanic	Black, Not Hispanic	Hispanic	Asian, Not Hispanic
Bridgeport	85.5	85.3	87.9			
Hartford	77.0	79.6	84.4	81.1	71.3	
New Haven	89.0	89.9	90.8	91.5		
HRG 1 (3)-UC	83.8	84.7	88.1	86.6	77.6

Connecticut	87.8	87.3	88.5	85.6	80.1	76.9
United States	85.9	85.9	86.3	89.8	85.2	

Source: DPH BRFSS Survey Data, 1999-2003; CDC BRFSS web site. Available at: www.cdc.gov/brfss. Accessed Sept. 8, 2005. Includes all women 18 and over, excluding women who have had a hysterectomy.
Note: All race and ethnicity specific rates are age-adjusted.
Blank cells indicate that data were not available due to small survey numbers or otherwise not calculated or available.

Asian and Hispanic women are least likely to have had a recent Pap smear test. Hartford has a particularly low rate for Hispanic women, even on an age-adjusted basis, and has the lowest rate for black women as well.

Sigmoidoscopy/Colonoscopy/Blood Stool Tests

The sigmoidoscopy and colonoscopy (Table 78) and blood stool (fecal occult blood) tests (Table 79) are recommended for detecting colorectal cancer beginning at age 50 for both men and women of average risk.

TABLE 78: SIGMOIDOSCOPY/COLONOSCOPY TEST AGE 50 AND OVER

AREA	All Race and Ethnicity, Crude Percentage	All Race and Ethnicity, Age-Adjusted Percentage	White, Not Hispanic	Black, Not Hispanic	Hispanic	Asian, Not Hispanic

Note: All race and ethnicity specific rates are age-adjusted.
Blank cells indicate that data were not available due to small survey numbers or otherwise not calculated or available.

Connecticut has a significantly higher sigmoidoscopy/colonoscopy rate (45.6 percent) than the United States (35.7 percent). There appears to be little difference in the rates for white, non-Hispanics, and the overall rate suggesting little disparity on this measure. Similarly, for blood stool tests (Table 79) there are virtually no differences between the U.S. rates, and black and white rates. The rate for Hispanics appears to be slightly lower than for blacks or whites.

TABLE 79: BLOOD STOOL TEST IN PAST YEAR, AGE 50 AND OVER

Prostate Screening

An annual prostate-specific antigen (PSA) blood test to detect possible prostate cancer is recommended for men beginning at age 50 and with at least a 10-year life expectancy. Men at heightened risk — black men and men with a family history of prostate cancer — are advised to start testing at 45 or even 40 years old.[89]

TABLE 80: PSA TEST IN PAST YEAR, MEN AGE 50 AND OVER

AREA	All Race and Ethnicity, Crude Rate	All Race and Ethnicity, Age-Adjusted Rate	White, Not Hispanic	Black, Not Hispanic	Hispanic	Asian, Not Hispanic

As shown in Table 80, close to 60 percent of Connecticut men age 50 and over report that they have had a PSA test in the past year.

HIV Tests

The number of people living with human immunodeficienty virus (HIV) infection in the United States continues to increase. Early detection is essential to reduce morbidity and mortality associated with HIV/AIDS. Some experts advocate routine HIV testing, although the Centers for Disease Control and Prevention (CDC) recommends testing based on risk assessment.[90]

HIV testing could be thought of as an indicator of physician practice in ordering tests for patients that they consider at high risk. It also could serve as protective behavior on the part of individuals who want the tests to protect themselves or others.

Overall, 45 percent of Connecticut adults age 18 to 64 reported ever being tested for HIV; 15 percent reported being tested in the past year. The Urban Centers had the highest percentage of reported HIV testing. There were no differences in HIV testing by city.

Black and Hispanic adults were more likely than white or Asian adults to have ever had an HIV test and to have had a test within the past year. There were higher HIV testing rates among blacks compared to whites in all HRGs with sufficient sample size to produce a reliable estimate. HIV testing among Hispanics as compared to whites was higher only in the Urban Centers and Diverse Suburbs. Asian adults were less likely than white adults to report ever being tested.

Note: All race and ethnicity specific rates are age-adjusted.
Blank cells indicate that data were not available due to small survey numbers or otherwise not calculated or available.

Cholesterol Tests

Cholesterol checks are particularly important in preventing cardiovascular disease. A finding of high cholesterol may lead to medication and recommendations for changes in diet and physical activity levels. The Behavioral Risk Factor Surveillance System (BRFSS) survey asks whether the respondent has received a cholesterol check in the past five years. Results are shown in Table 83.

TABLE 83: CHOLESTEROL CHECK IN PAST FIVE YEARS

AREA	All Race and Ethnicity, Crude Percentage	All Race and Ethnicity, Age-Adjusted Percentage	White, Not Hispanic	Black, Not Hispanic	Hispanic	Asian, Not Hispanic
Bridgeport	75.6	76.6	77.8	79.5	76.2

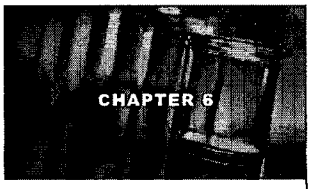
Note: All race and ethnicity specific rates are age-adjusted.
Blank cells indicate that data were not available due to small survey numbers or otherwise not calculated or available.



These results indicate a lower level of cholesterol checks for black, Hispanic and Asian adults statewide than for white adults, but there are no statistically significant differences among HRGs.

CLINICAL PREVENTIVE MEASURES

Flu Vaccine

More than 36,000 people nationally die from influenza each year. Elderly adults, young children and people with certain health conditions are at high risk for complications. The CDC recommends that all adults 50 and older receive a yearly flu vaccine. Adults over age 65 are considered one of the groups at highest risk and are given priority status for influenza vaccine administration.[91] The *Healthy People 2010* initiative aims for 90 percent of adults age 65 and older to have received a flu vaccine within the past year.[92]

Overall, 70 percent of Connecticut adults age 65 and older reported receiving a flu shot in the past year as did 40 percent of adults aged 50-64. Receipt of flu shots in both age groups varied somewhat by HRG, though sample sizes were too small to detect significant differences. Sample sizes were also insufficient to detect city differences in flu shot receipt.

Hispanic adults in the 50-64 year age group were more likely to receive a flu shot than black and white adults. Among adults age 65 and older, blacks are significantly less likely than whites to have received a flu shot.

Pneumonia Vaccine

The CDC estimates that 500,000 people nationwide contract, and 40,000 die from, pneumococcal pneumonia each year. The elderly are at greater risk than younger adults for serious illness and death from the disease. Pneumonia vaccine is recommended for all adults age 65 and older, as well as for younger adults with serious long-term health problems.[93] The *Healthy People 2010* initiative aims for 90 percent of adults age 65 and older to receive a pneumonia vaccine.[94]

Overall, over 60 percent of Connecticut's adults age 65 and older report ever having had pneumonia vaccine, as presented in Table 86. The percentage varied slightly by HRG, from 54 percent receiving the vaccine in the Urban Centers to 63 percent in the Mill Towns. There were no statistically significant differences in pneumonia vaccine by city.

White Connecticut residents age 65 and older were more likely than their black and Hispanic counterparts to report ever receiving a pneumonia vaccine. In contrast, white residents ages 50 to 64 were less likely than their black and Hispanic counterparts to have received pneumonia shots, as shown in Table 87.

CHAPTER 9
HEALTH OUTCOMES: HEALTH STATUS, DISEASE INCIDENCE, HOSPITALIZATION, AND MORTALITY

Of the many possible indicators of health outcome, the following are included in this report:

- Health status
- Disease incidence
- Hospitalization
- Emergency department utilization (ED)
- Mortality

SELF-REPORTED HEALTH STATUS

Self-reported health status is a strong predictor of future illness, death, and use of health care.[187] Physical and mental health are both important components of health status.

Twelve percent of state residents reported their health to be fair or poor, according to the Behavioral Risk Factor Surveillance System (BRFSS) surveys of adults 18 years old and older that were conducted between 1999 and 2003, reported in Table 97. Eight percent reported having 15 or more days of poor physical health in the past month, and 8 percent reported 15 or more days of poor mental health in the past month.

There were differences in self-reported health status by Health Reference Groups (HRGs), adjusted for age differences. Although more than one-fifth of residents in the Urban Centers reported that their overall health was fair or poor, only 8 percent of residents in the Wealthy Suburbs and 9 percent of residents in the Rural Towns reported fair or poor overall health.

Residents in the Urban Centers were also much more likely to report poor physical health (Table 98) and poor mental health (Table 99) than residents in the Manufacturing Centers and Wealthy Suburbs. Self-report of poor physical health was also high in the Manufacturing Centers, while poor mental health was relatively high in the Diverse Suburbs.

Hispanic respondents were more likely than white or black respondents to report fair or poor health. This difference was most evident for residents in the Urban and Manufacturing centers. Asian respondents were the least likely to report fair or poor overall health. They were also least likely to report 15 or more days of poor physical health or poor mental health.

Self-Reported Health Summary

Self-reported overall health and physical health is lowest in the Urban Centers, as summarized in Table 100. Poor mental health shows a more variable pattern. The communities in the Wealthy Suburbs group have the most favorable self-reported health on all three indicators.

TABLE 100: AGE-ADJUSTED PERCENTAGES OF PERSONS 18 AND OVER WITH SELECTED SELF-REPORTED HEALTH LEVELS, BY HRG, BRFSS SURVEYS 1999-2003

AREA	Fair or Poor Overall Health	Poor Physical Health 15 or More Days in Past Month	Poor Mental Health 15 or More Days in Past Month

DISEASE INCIDENCE

ASTHMA

Asthma is the seventh-ranked chronic health condition in the United States, causing almost 500,000 hospitalizations and 5,000 deaths per year. Asthma-related health care costs are estimated at $14.5 billion a year. The incidence of asthma, asthma-related health care costs, and deaths due to asthma increases each year.[188]

Overall, 12.4 percent of Connecticut adults report ever being diagnosed with asthma (Table 101), and 8.3 percent report currently having asthma, as shown in Table 102. Prevalence of both lifetime and current asthma was highest in the Urban Centers and lowest in the Wealthy Suburbs. Sample sizes were insufficient to detect differences in asthma prevalence by city.

Prevalence of lifetime and current asthma was similar among white, black and Hispanic respondents, but it was somewhat lower among Asian respondents. While the asthma prevalence among Hispanics was similar to that of whites and blacks in the Urban and Manufacturing centers and Diverse Suburbs, the prevalence of lifetime and current asthma was lower among Hispanics in the Wealthy Suburbs than among whites.

ARTHRITIS

Arthritis refers to a variety of disorders, the most common of which is osteoarthritis, or degenerative joint disease. Osteoarthritis, affecting mostly older people, results from the wearing away of the cartilage that covers the ends of bones in a joint, causing pain, swelling and loss of motion. Osteoarthritis affects more than 20 million people in the U.S., and is one of the most frequent causes of physical disability among adults.[189]

Blank cells indicate that data were not available due to small survey numbers or otherwise not calculated or available.

Overall, 40 percent of Connecticut adults age 50 and older reported being diagnosed with arthritis (Table 103). There were no statistically significant differences in the prevalence of arthritis by HRG or city. A similar percentage of white, black, Hispanic, and Asian respondents age 50 and older reported being diagnosed with arthritis.

OSTEOPOROSIS

Osteoporosis involves deterioration of bone tissue, leading to bone weakness and increased risk of fractures of the hip, spine and wrist. Although the disease affects both sexes, 68 percent of those with osteoporosis are women. This difference may be due in part to the older age distribution of women. Risk of osteoporosis is reduced among individuals with a lifetime diet high in calcium and vitamin D. Other risk factors for the disease include cigarette smoking and lack of exercise.[190]

Overall, almost 9 percent of women age 40 and older reported being told by a doctor that they had osteoporosis (Table 104). Although the prevalence of osteoporosis in this group appeared to vary by HRG, sample sizes were too small to detect statistically significant differences. Sample sizes were also insufficient to examine racial and ethnic differences in the prevalence of osteoporosis.

DIABETES

Diabetes is a disease in which the body does not produce or properly use insulin. Type 2 diabetes, the most common type, may result in serious complications including heart disease, blindness, nerve damage, and kidney damage.[191] The *Healthy People 2010* initiative sets a target level of no more than 2.5 percent diabetic in the adult population.[192]

Over 5 percent of Connecticut residents reported having diabetes (Table 105). Diabetes prevalence varied by HRG. Residents in the Urban Centers had the highest prevalence of diabetes, more than twice that of residents living in the Wealthy Suburbs.

In the Urban and Manufacturing centers, the prevalence of diabetes was higher among black and Hispanic adults than among white adults. Sample sizes were insufficient to detect statically significant race and ethnicity differences in diabetes between the other HRGs and between the cities of the Urban Centers.

BIRTH WEIGHT

Birth weight is an important predictor of neonatal mortality and future health problems. Low birth weight (LBW) is less than 5 pounds, 8 ounces (2,500 grams) at birth. Very low birth weight (VLBW) is less than 3 pounds, 5 ounces (1,500 grams). There are two different forms of low birth weight: "preterm births" and "small-for-date babies." The latter are full-term babies who are below the weight guidelines.

Low birth weight affects about one in every 13 babies born each year in the United States, and it is a factor in 65 percent of infant deaths. Low birth weight babies may face serious health problems as newborns and are at increased risk of long-term disabilities.

The factors influencing low birth weight are only partly understood, and they include genetic or environmental conditions that limit normal development, as well as mothers' medical problems. Mothers' substance use and abuse has also been correlated with low birth weight.[193]

TABLE 106: PERCENTAGE LOW OR VERY LOW BIRTH WEIGHT, 1999-2003

AREA	All Race and Ethnicity	White, Not Hispanic	Black, Not Hispanic	Hispanic	Puerto Rican	Non-Puerto Rican Hispanic
HRG 1 (3)-UC	13.2	9.0	17.0	11.7	13.2	7.2
HRG 2 (10)-MC	9.8	8.0	16.7	9.7	12.6	6.3
HRG 3 (15)-DS	8.9	7.8	14.4	9.9	11.5	7.4
HRG 4 (27)-WS	6.6	6.8	14.8	5.4

Connecticut	9.1	7.6	16.3	10.3	12.8	6.5

Source: DPH.

Black non-Hispanics have the highest rate of low or very low birth weight, followed by Puerto Rican Hispanics, whites, and non-Puerto Rican Hispanics, whose rates for LBW or VLBW are slightly lower than those for whites in every HRG.

MORTALITY

Any health planning effort requires an examination of mortality patterns, but since mortality often reflects behavioral risks and chronic diseases developed over many years, mortality should be examined along with the risk behaviors and environmental conditions presented in other chapters of the *Data Scan*.

Since the populations being compared in the *Data Scan* are very different in age distribution (Hispanic and Asian populations are younger than the black population, which in turn is younger than the white population), crude mortality rates make for "unfair" comparisons. Age adjusting allows for fair comparisons among Connecticut mortality rates, as shown in Tables 107-111.

TABLE 107: ANNUALIZED CRUDE AND AGE-ADJUSTED MORTALITY PER 100,000 FROM ALL CAUSES, 2000-2004

Data note on mortality counts and rates

An average of about 150 deaths per year are from Other Races, American Indian or Unknown and are excluded from the race-specific tables. The race-specific tables include a small number of persons of mixed race in the numerators who may be listed as black, white or Asian. U.S. Census Bureau denominator data excludes these persons, producing slightly smaller denominators and a slight elevation in crude and age-adjusted race-specific rates. In 2000, of 30,140 deaths, 1,249 or 4.1 percent were missing the Hispanic identifier. Persons for whom the Hispanic identifier was missing were assigned by DPH to non-Hispanic race specific categories in data made available for this study. The overall white non-Hispanic, black non-Hispanic and Asian non-Hispanic rates may be slightly elevated due to the assignment of "Hispanic missing" cases to these non-Hispanic groups. In the test year of 2000, the white non-Hispanic crude death rate was 984.0 per 100,000 population without the white missing Hispanic ethnicity and 1023.7 when white missing Hispanic ethnicity cases were reassigned to white non-Hispanic ethnicity. Similarly, black non-Hispanic crude rates were 649.3 and 681.4 and Asian non-Hispanic crude rates were 134.9 and 144.7 per 100,000 population.

The mortality rates produced for the *Data Scan* differ slightly from the rates available from some state and federal government sources. The federal rates are for whole states. Detailed estimates of state populations for age by sex by race and ethnicity groups are updated each year to provide denominators to calculate age-adjusted rates. In the *Data Scan*, age by sex by race and ethnicity data at the town level were required to produce mortality rates for HRGs. These required population estimates were not available for the years 2001-2004. While the numerator mortality count data were from the period 2000-2004, denominator population data from the 2000 U.S. Census only were used in the mortality rate calculations. Since the Connecticut population increased slightly from 2000-2004, the overall mortality rates reported here may be slightly higher than mortality rates reported elsewhere, because the *Data Scan* rates are based on slightly smaller denominators than those used elsewhere.

The Asian mortality rates are extremely low, consistent with those in other areas of the United States. The relative youth of this population does not account for the crude mortality differences. For example, the percentages under 35 years old for the black and Asian populations are relatively similar — 57.7 percent and 59.3 percent, respectively — yet the crude mortality rates are vastly different — 657.8 and 160.2 per 100,000 population.

The black population has a large discrepancy between crude and age-adjusted mortality. On the basis of crude rates, for example, black mortality is markedly lower than white mortality for each HRG and for Connecticut as a whole. But this occurs because of the large difference in age distribution. Taking age structure into account, the age-adjusted mortality rates for blacks are much higher than for whites as shown in Table 112.

There is also a large discrepancy between the crude and age-adjusted rates for Hispanics because the Hispanic population is much younger than the U.S. population used for age adjustment. Correcting for differences in the age distribution, the Hispanic death rate remains higher in the Urban Centers than in any of the other HRGs. It is lowest in the Wealthy Suburbs. Thus, there is a marked discrepancy among Hispanics depending on their HRG of residence.

Since residential locations differ for various Hispanic subgroups, e.g., Puerto Rican versus non-Puerto Rican Hispanics, this mortality difference may be related to Hispanic subgroup differences between HRGs. But this suggests more fundamental questions about differences in life circumstances and lifestyles *within* broad race and ethnicity categories that cannot be answered with the available data.

TABLE 112: RATIO OF RACE/ETHNICITY SPECIFIC ALL-CAUSE MORTALITY RATE TO WHITE NOT HISPANIC AGE-ADJUSTED MORTALITY RATE, 2000-2004

AREA	Asian Not Hispanic Rate to White Not Hispanic Rate	Black Not Hispanic Rate to White Not Hispanic	Hispanic Rate to White Not Hispanic
HRG 1 (3)-UC	69.6%	124.5%	86.7%

HRG 6 (75)-RT	75.4%	119.6%	61.7%

Source: Data Scan Tables 108-111. All rates are age-adjusted.

Conclusions from All-Cause Mortality Data

After the data is age-adjusted, Asian and Hispanic death rates are lower than white and black death rates (Table 112). This major finding also may be due in part to the so-called "Healthy Immigrant Effect" or, for Latinos/Hispanics, the "Latino Paradox."[194] The basic finding is that recent black and Latino/Hispanic immigrants are healthier despite having lower incomes and less health insurance. But their health worsens as they acculturate to U.S. lifestyles. Some of this affect, for Hispanics, may be due to the recently discovered "born Hispanic, died white" effect, where some Hispanics may be identified on death certificates by funeral directors as white, without information about their Hispanic status.[k] Thus, Hispanic deaths may be slightly underreported relative to their numbers in the population.

Overall, black death rates are significantly higher than white death rates after age adjustment. This pattern exists in each HRG.

Specific Causes of Mortality

Table 113 provides major cause rates for all ages; Table 114 provides them for persons dying before age 75; and Table 115 provides Years of Potential Life Lost (YPLL). Appendix K provides a complete list of deaths by cause.

Conclusions from the Mortality Cause Data — All Ages

As the data show, the black population has the highest age-adjusted mortality rate — except for suicide, pneumonia and motor vehicle deaths — whether one considers all mortality or mortality before age 75.

The rate ratios for blacks compared with the overall population rate are especially elevated for HIV/AIDS (30.9:5.3 = 5.8:1), homicide (14.1:3.2 = 4.1:1), diabetes (46.4:18.3 = 2.5:1), and cardiovascular disease (366.6:278.3 = 1.3:1). Their rate for suicide is lower than the overall population rate (4.8:8.0 = 0.6:1). Black males show a significantly elevated death rate before age 75 from prostate cancer (15.5:6.1 = 2.5:1).

The Asian population shows a lower rate on all indicators and on many indicators their rate is less than half the all-group rate.

The Hispanic population shows a mixed pattern. There are higher mortality rates for HIV/AIDS (20.8:5.6 = 3.7:1), homicide (6.1:3.2 = 1.9:1) and diabetes (14.3:8.6 = 1.7:1). They have lower rates for suicide (5.7:7.9 = 0.7:1).

Years of potential life lost are greatest for cancer, particularly lung cancer. The next greatest YPLL is for cardiovascular disease, and then accidental injury. These causes have relevant community-level interventions.

The complex pattern of differential causes of death for different race and ethnicity groups requires explanation. At least four explanations have been advanced:

- Differential access to and use of quality health care
- Cultural differences in behaviors that have health consequences
- Biohistorical differences that affect susceptibility to specific diseases in the modern U.S. culture
- The "healthy immigrant" theory

These competing hypotheses cannot be resolved with the information available in the *Data Scan*.

CHILD MORTALITY

The state Connecticut Department of Children and Families (DCF) reports that Connecticut has the third-lowest overall rate of child fatalities in the United States. The state was the fourth lowest in the nation in 2002 fatalities due to accident, suicide, or homicide in youth ages 15–19, at a rate of 34 per 100,000.[195] The 2002 report was DCF's last comprehensive annual report on child fatalities. According to the National Center for Health Statistics, the 2000 mortality rate for children 0–19 years old in Connecticut was 52.2 deaths per 100,000 population. The infant mortality rate (ages 0 to 1 year) was 6.6 per 1,000 live births.[196] The state Department of Public Health reports that the leading cause of death among children ages 1 to 19 in 2003 was unintentional injury, and among these motor vehicle incidents were the greatest number. Table 116 provides the leading causes of child mortality.

TABLE 116: 10 LEADING CAUSES OF DEATH IN CHILDREN (AGES 0-19) IN CONNECTICUT, 2003

AGE GROUP	Cause	Count
< 1	Short Gestation and Low Birth Weight	40
	Congenital Anomalies	34
1 - 4	Accidents (unintentional injury)	9
	Motor Vehicle	4
	Heart Disease	3
5 - 9	Accidents (unintentional injury)	6
	Motor Vehicle	5
	Malignant Neoplasms	4
10 - 14	Malignant Neoplasms	8
	Accidents (unintentional injury)	7
	Motor Vehicle	2
15 - 19	Accidents (unintentional injury)	48
	Motor Vehicle	29
	Poisoning	11
	Homicide	11
	By Firearm	8

Source: DPH Connecticut Resident Deaths, 2003: Top Five Leading Causes of Death by Age and Sex. Available at: http://www.dph.state.ct.us/OPPE/RR2003/RR2003_T10.xls. Accessed Feb. 3, 2007.

In cases of child mortality in which abuse may have been a possible cause of death, DCF conducts an investigation independent of medical examiner findings. DCF also notes that some deaths are ruled as homicides by the police, although medical and judicial findings may differ. According to DCF, 3 percent of child deaths reported in 2002 were the result of abuse — including skull fractures, intentional suffocation, and shaken baby syndrome.[197]

EMERGENCY DEPARTMENT UTILIZATION (ED)

Several types of emergency department (ED) utilization fall within the general heading of health outcomes. Two of these are assaults and suicide attempts. The data for these two indicators show very different patterns, by HRG.

TABLE 117: EMERGENCY DEPARTMENT UTILIZATION PER 100,000, 2002-2003

AREA	Assaults	Suicide Attempts
HRG 1 (3)-UC	10.1	1.8
HRG 2 (10)-MC	5.6	1.5
HRG 3 (15)-DS	3.9	1.6
HRG 4 (27)-WS	1.3	0.9
HRG 5 (39)-MT	2.7	1.5
HRG 6 (75)-RT	2.0	1.3
Connecticut	3.9	1.3

Source: Connecticut Health Information Management and Exchange (CHIME) Database, Connecticut Hospital Association (CHA).

The HRG rates for ED visits for assaults shown in Table 117 follow a familiar pattern from highest to lowest: Urban Centers > Manufacturing Centers > Diverse Suburbs > Mill Towns > Rural Towns > Wealthy Suburbs. Suicide shows a less clear pattern, except that the Urban Centers have twice the rate of suicide-related ED visits as the Wealthy Suburbs (1.8:0.9 = 2:1). The assault rate ratio between the Urban Centers and the Wealthy Suburbs is 10.1:1.3 = 7.8:1, a rate ratio for assault-related visits that is more than triple that of suicide-related visits.

These data do not suggest a clear reason for this difference in pattern for violent impulses turned outward (assault) versus inward (suicide), but the topic is worth further investigation.

CANCER INCIDENCE

Cancer incidence is reportable to the Connecticut Tumor Registry, within DPH. Cancer incidence data for this study have been aggregated into HRGs and reported by race and ethnicity. The cancer incidence rate data may, therefore, be analyzed by HRG to develop hypotheses about potential environmental and lifestyle risk factors and then design interventions.

TABLE 118: AVERAGE ANNUAL AGE-ADJUSTED CANCER INCIDENCE RATES PER 100,000 FOR CONNECTICUT, 1998-2002

RACE AND ETHNICITY	HRG 1 (UC)	HRG 2 (MC)	HRG 3 (DS)	HRG 4 (WS)	HRG 5 (MT)	HRG 6 (RT)	State
Colorectal Cancer							
White-alone, Not Hispanic	70	65	65	57	64	61	63
Black-alone, Not Hispanic	64	59	53	38L	72	58	60

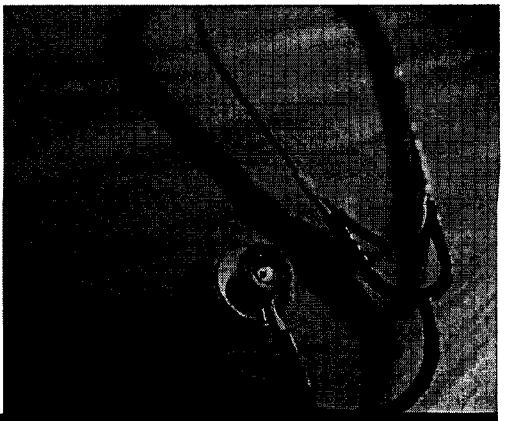
Source: Counts of cancers were obtained from the Connecticut Tumor Registry (CTR), DPH; Rates were calculated by the author using cancer counts as numerators and U.S. Census 2000, SF1:Tables PCT12, PCT12H,I,J as denominators.

Notes: (1) Invasive cancers only are included in the table. (2) Since Connecticut populations of interest have very different age distributions, all incidence rates are age-adjusted. Cancer incidence counts for three broad age categories (60; 60-79; 80+ years) were available from the CTR without the need to seek approval from the DPH Human Investigations Committee. Therefore, the age-adjusted rates reported here are slightly different than those computed using five-year age groups. (3) According to the CTR, some errors in coding of "Hispanic" occur because hospitals do not ascertain Hispanic ethnicity for all cancer patients. The CTR, along with many other U.S. cancer registries performs Spanish-surname matching in an attempt to improve identification of patients who might identify themselves as Hispanic/Latino. These results were included in the numerator data used in the table. (4) Race and ethnicity specific rates significantly below the total rate for the state are labeled "L" and those significantly above the state rate are labeled "H." (5) Certain data used in this study were obtained from the CTR, located in DPH. The author assumes full responsibility for analyses and interpretation of these data.



The most significant findings in Table 118 are that black males are significantly high in prostate cancer incidence in every HRG but the Rural Towns, where the difference is not large enough to be statistically significant given the small underlying population. Blacks have a lower rate for colorectal cancer in the Wealthy suburbs; and a lower rate for breast cancer in the Urban and Manufacturing centers and Mill Towns.

Hispanics are below the overall Connecticut rates on several cancer indices, including: colorectal cancer in the Urban Centers and Diverse and Wealthy suburbs; lung cancer in the Urban and Manufacturing centers and Diverse Suburbs; and breast cancer in all but the Rural Towns.

Some of the differences for Hispanics are possibly due to difficulties in age adjustment. The age categories used for the data provided for this study by the Tumor Registry were "under 60," "60-79," and "80 and over." These broad categories were used so as to preserve confidentiality. Since the Hispanic population is very young, these age categories may not have yielded a sensitive enough age adjustment. Another factor producing lower Hispanic rates may be the potential undercounts suggested in the Table 118 notes.

Some persons may be included in the rate numerators (e.g., multiracial black non-Hispanic residents) but excluded from rate denominators (black-alone non-Hispanic residents). Therefore, the rates reported here, as all rates, should be treated as estimates only, with some potential for bias.

Asian cancer incidence rates are not available due to small counts and preservation of confidentiality.

CHAPTER 11

SUMMARY AND RECOMMENDATIONS

Six focus areas are suggested to improve the health of the people of Connecticut by: increasing access to high quality care; promoting disease prevention, wellness, and active management of chronic health problems; and securing improvement of health outcomes and wise use of resources. Additional factors considered in selecting these areas were that they: show a significant amount of racial/ethnic disparity; involve risk factors that are likely to produce significant future health problems; or be health risks and conditions that are elevated above the *Healthy People 2010* national targets.

The focus areas are:

- Health Reference Groups (HRGs), and race and ethnicity groups in greatest need
- Diabetes and other conditions in the metabolic syndrome
- The medical home
- The binge drinking and smoking culture
- Youth risks and opportunities
- The health data system

The following sections explore each of these focus areas in detail.

FOCUS AREA 1 — FOCUS ON THE HEALTH REFERENCE GROUPS (HRGs) AND RACE AND ETHNICITY GROUPS IN GREATEST NEED

Many methods could be used in setting priorities and determining focus areas for future effort. These are discussed in Appendix L.

Findings and Analysis

Most of the data in the *Data Scan* are organized according to the HRGs previously described. On almost all measures of health risk and outcome, the ordering of HRGs is, from most to least risk and from poorest to best health outcomes: Urban Centers > Manufacturing Centers > Diverse Suburbs > Mill Towns > Rural Towns > Wealthy Suburbs.

The rates for black residents show significantly greater risk or poorer outcomes on more indicators than other race/ethnicity groups, even after controlling for HRG of residence. The rates for Asian residents, where available, show the lowest rates of risk and the best outcomes. Rates for Hispanic residents are mixed. On some indicators they show higher health risks and poorer health outcomes than other groups, but on other indicators they show better outcomes, if not better risk status. This pattern may be due to significant variation within the Hispanic ethnicity group, particularly between Puerto Rican and non-Puerto Rican Hispanics.

Quantitative Data on Health: Selected Measures

The full *Data Scan* includes more than 170 tables and figures showing health and related indicators for individual cities and towns, HRGs and Connecticut as a whole. Table 119 illustrates the rates for a selection of these measures, which were used to estimate needs in each of the HRGs. The indicators were selected to represent a wide variety of aspects of health. This was done so that no one area would be overrepresented in the needs analysis.

The rates shown in Table 119 follow a pattern similar to self-reported overall poor health: Urban Centers > Manufacturing Centers > Diverse Suburbs > Mill Towns > Rural Towns > Wealthy Suburbs.

TABLE 119: SELECTED INDICATORS OF HEALTH, BY HEALTH REFERENCE GROUP

INDICATOR	Connecticut	3 Urban Centers	10 Manufacturing Centers	15 Diverse Suburbs	27 Wealthy Suburbs	39 Mill Towns	75 Rural Towns
Population, 2000	3,405,565	384,733	662,398	587,504	487,620	698,517	584,793
Accepted Child Abuse Cases per 1,000, 2001-2005	36.8	68.2	53.2	43.8	9.8	32.0	19.8
Crimes Reported per 1,000, 2002-2003	30.0	76.1	39.5	29.5	13.0	22.7	12.1
Car Crashes with Injury per 1,000, 2002	9.4	15.8	10.7	8.5	7.8	8.3	7.2
STD Rate per 1,000, 2000-2004	5.8	21.5	7.6	4.6	0.8	1.7	1.1
Teen Births 15-19 per 1,000, 1999-2003	24.0	57.3	39.9	22.2	2.9	13.0	7.3
Percentage Self-Reported Employment Related Disability for Persons 21-64, 2000	11.3	17.7	14.4	12.5	6.4	10.0	8.4
Percentage Obese: Calculated from Self-Reported Height and Weight, 18 and Older, 1999-2003	17.2	23.5	18.2	19.2	11.0	18.0	15.1
Emergency Department (ED) Visits per 1,000, 2002-2003	387.4	607.6	498.3	404.6	214.6	343.6	295.9
Deaths Before Age 75 per 100,000, 2000-2002	350.3	444.0	381.1	366.4	244.2	372.3	300.0

Source: See "Data Scan" text tables.

There is a large difference in the size of the differentials for the various indicators. For example, the rate ratio of sexually transmitted disease (STD) case rates for the Urban Centers to the Wealthy Suburbs is 21.5:0.8 = 26.9:1. The rate ratio between Urban Centers and Wealthy Suburbs for overall mortality before age 75 is only 444.0:244.2 = 1.8:1. Thus, HRG of residence makes a much greater difference for STD rates than for mortality rates. The differences cannot be accounted for by age distribution differences between the HRGs.

Community Need Calculations

One approach to estimating comparative need in each of the HRGs is to estimate the percentage of the total need in the state attributable to each HRG.

Table 120 converts the rates from Table 119 into percentages for each HRG, based on relevant population size, and then summarizes the need in each HRG by averaging all of the selected indicators.

A summary of the results in Table 120 indicates that half (49.1 percent) of the total need in the state is attributable to the 13 communities in the Urban and Manufacturing centers, compared with their 31.8 percent of the total population for the state. Conversely, 50.9 percent of the need exists in the remaining 156 communities with 68.2 percent of the total population.

Recommendations

Resources could be allocated among HRGs, approximating the percentage distribution of need, over the broad set of indicators: 24.0 percent to the three Urban Centers; 25.1 percent to the 10 Manufacturing Centers; 17.3 percent to the 15 Diverse Suburbs; 6.8 percent to the 27 Wealthy Suburbs; 16.4 percent to the 39 Mill Towns; and 10.4 percent to the 75 Rural Towns, as shown in Figure 28.

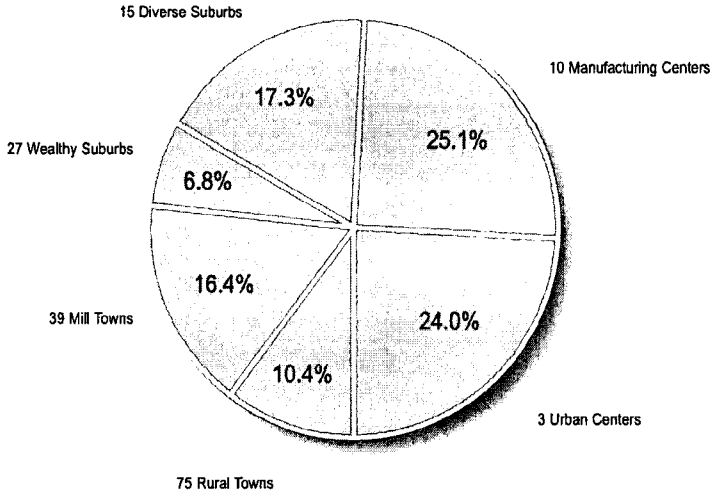


TABLE 120: PERCENTAGES OF TOTAL CONNECTICUT ESTIMATED NEED, FOR SELECTED INDICATORS, BY HEALTH REFERENCE GROUP

INDICATOR	3 Urban Centers	10 Manufacturing Centers	15 Diverse Suburbs	27 Wealthy Suburbs	39 Mill Towns	75 Rural Towns
Accepted Child Abuse Cases	23.7	26.9	19.1	4.2	16.5	9.6
Crimes	28.7	25.6	17.0	6.2	15.5	6.9
Car Crashes with Injury	19.0	22.2	15.6	12.0	18.1	13.2
Sexually Transmitted Disease/Known Residence	45.5	27.6	14.8	2.2	6.4	3.5
Teen Births 15-19	35.5	31.6	15.5	1.6	10.9	4.9
Self-Reported Employment Related Disability for Persons 21-64	16.9	25.2	18.4	8.0	18.6	12.9
Obesity: Calculated Self-Reported Height and Weight, 18 and Older	14.6	20.7	19.5	8.7	21.8	14.7
ED Visits	17.7	25.0	18.0	7.9	18.2	13.1
Average Deaths < 75	14.6	21.1	17.8	10.0	21.6	14.9
Average, All Measures	24.0	25.1	17.3	6.8	16.4	10.4
Population (Percentage)	11.3	19.5	17.3	14.3	20.5	17.2

Source: See "Data Scan" text tables.

Somewhat greater weight beyond the crude percentages could be given to health risks in the Urban and Manufacturing centers since their populations are generally younger, and these risks represent significant future problems. Key populations at risk are the black and Puerto Rican Hispanic residents in the three Urban Centers and in the 10 Manufacturing Centers, as they have the largest health risks beyond those that would be predicted based on their HRG residence alone. The concentration of black and Hispanic residents in these areas is discussed in Chapter 3, Connecticut Community Profile, and in Appendix C.

FIGURE 28: PERCENTAGE DISTRIBUTION OF ESTIMATED NEED BY HRG

FOCUS AREA 2 — FOCUS ON DIABETES AND OTHER CONDITIONS IN THE METABOLIC SYNDROME

Findings and Analysis

Type 2 diabetes may lead to serious complications, including heart disease, blindness, nerve damage, and kidney damage.[201] There are clear racial and ethnicity disparities in risk factors, incidence, hospitalization, and mortality due to diabetes.

Diabetes Incidence

Age-adjusted rates of Connecticut residents "ever told they have diabetes" are 4.7 percent for the white population age 18 and over, 8.8 percent for the black population, 7.5 percent for the Hispanic population, and 5.3 percent for the Asian population.

In contrast, the *Healthy People 2010* objective is for no more than 2.5 percent of the adult population with a diagnosis of diabetes.[202] Thus, diabetes is a problem for all racial and ethnic groups, but it is particularly for black and Hispanic residents.

Diabetes Mortality Disparities

The age-adjusted diabetes mortality rate before age 75 for Connecticut overall (2000-2004) is 8.6 per 100,000. For whites, the age-adjusted rate is 7.4 per 100,000 residents, while it is 23.0 per 100,000 for black residents, 14.3 for Hispanics, and 2.7 for Asians. Thus, blacks have almost triple the "premature" diabetes mortality of whites.

Diabetes is not only a prevalent condition, but it is also a good "index" for examining chronic disease disparities, since there are data at each level in the causal chain. Diabetes can also be understood as part of a larger concept of the "metabolic syndrome" — a group of related conditions including diabetes, heart disease and stroke.

Diabetes and Ambulatory Care Sensitive Conditions

Diabetes and metabolic syndrome care are particularly important markers for understanding health disparities.

Of the 16 conditions tracked by the Office of Healthcare Access (OHCA), the hospitalization ratio of rates for blacks to rates for all races is highest for hypertension (rate ratio of 89.1:24.7 = 3.6:1); next highest for uncontrolled diabetes (rate ratio of 26.1:7.4 = 3.5:1); followed by diabetes short-term complications (rate ratio of 143.5:42.5 = 3.4:1); and diabetes long-term complications (rate ratio of 263.2:105.8 = 2.5:1). One additional condition potentially related to diabetes, lower extremity amputation, ranks seventh in this rate-ratio comparison at 83.2:38.0 = 2.2:1.

Ambulatory care sensitive conditions (ACSCs) are conditions for which hospitalization could be avoided through appropriate ambulatory care. ACSC conditions are good markers for how well the health care system provides, and residents utilize preventive services and care in appropriate settings. The ACSCs are discussed more broadly in the section of this chapter on the "Medical Home," as well as in Chapter 7: Health Care Quality.

The high rate ratios for these metabolic syndromes and ACSC conditions for the black population, even utilizing crude rates that underestimate the age-adjusted rates, are cause for serious concern about this health disparity.

Risk Factors: Obesity and Lack of Physical Exercise

Obesity and lack of physical exercise are key modifiable risk factors for diabetes and metabolic syndrome diseases. There has been a significant increase in obesity in the past decade, both nationally and in Connecticut. There are also significant disparities that could worsen if they are not addressed. The black population is especially at risk.

Behavioral Risk Factor Surveillance System (BRFSS) data for Connecticut demonstrate that 15.9 percent of the age-adjusted 18 and over white population is considered obese under national guidelines; 30.9 percent of the black population; 21.6 percent of the Hispanic population; and 4.2 percent of the Asian population. Within the black population females are more likely obese than males in all age groups 30 and over.

High blood pressure is another aspect of metabolic syndrome. According to self-report, this condition affects 28.0 percent of the white population 18 and over; 37.1 percent of the black population; 27.2 percent of the Hispanic population; and 26.5 percent of the Asian population.

Self-reported rates of "no physical activity" are 20.3 percent of the white population; 34.9 percent of the black population; 40.6 percent of the Hispanic population; and 28.3 percent of the Asian population.

These rates suggest a looming future problem of metabolic syndrome diseases among all populations, but particularly among blacks and Hispanics.

Obesity: The Special Case of Immigrants

Although immigrants are less obese than native-born residents of the United States, this comparative advantage disappears the longer they are in the country. In one survey, immigrant respondents "were less likely to be overweight or obese" than the U.S.-born respondents (16 percent vs. 22 percent). Eight percent of those who had lived in the United States for less than one year were obese. But 19 percent of those who had lived in the country for at least 15 years were obese. This relationship between body mass index (BMI) and years of residence held true for all racial/ethnicity groups except foreign-born blacks.[203]

This research has led to several studies aimed at finding the roots of the apparent tendency for immigrants to adopt less healthy lifestyles the longer they reside — and presumably the more they acculturate — in the United States. Women in one focus group study suggested that limited time for family, cooking, and food shopping, as well as such obstacles as lack of transportation and child care, influenced the diets of long-term immigrant residents — rather than scarcity of food or physical access to grocery stores.[204]

Metabolic Syndrome Disparities Develop Early

The Youth Risk Behavior Survey (YRBS) at the state and national levels, as well as the National Health and Nutrition Surveys (NHANES), contain data on key indicators for youth adopting lifestyles that may lead to metabolic syndrome conditions later in life. Both surveys show that high school students are at increasing risk due to increased rates of overweight and decreased rates of physical activity.

The risks are especially acute among black and Hispanic teens.[205] According to the Connecticut School Health Survey (available at: http://www.dph.state.ct.us/PB/HISR/CSHS.htm), 9.2 percent of white high schoolers in Connecticut were overweight (at or above the 95th percentile for body mass index) in 2005. By comparison, 15.4 percent of black and 17.9 percent of Hispanic high schoolers were overweight. The difference between white and Hispanic students is statistically significant.

The survey also found that white students (67.2 percent) were more likely to have engaged in vigorous physical activity than black (53.6 percent) or Hispanic (52.1 percent) students. The white-Hispanic differences are statistically significant.

These differences were consistent with the rates of those who "watch TV three or more hours per day." The self-reported percentages were significantly lower for white students (27.9 percent) than for black students (59.1 percent), and Hispanic students (42.6 percent).

The race/ethnicity differences for Connecticut are consistent with data from national surveys and similar states (e.g., Massachusetts and Rhode Island). Further detailed data are available in Chapter 4, Health Risk and Health-Promoting Behaviors.

Prevention Is the Key

The Mayo Clinic's "Tools for Healthier Living" suggest that the primary goal for metabolic syndrome is to *prevent* the development of type 2 diabetes, heart attack and stroke. This can usually be accomplished with an aggressive regimen of self-care strategies focusing on diet and exercise.

Mayo recommends: eating a healthy diet with fruits, vegetables, beans and other fiber foods, white meat or fish; avoiding processed or deep fried dinners, eliminating table salt; participating in at least 30 minutes of moderately strenuous activity most days of the week; undergoing regular screenings for blood pressure; and stopping smoking.[206]

The Connecticut Medicaid Managed Care Council's Quality Assurance Subcommittee has developed recommendations regarding childhood obesity. Rather than the traditional view that obesity reflects a lack of discipline in choosing an appropriate diet and adequate physical activity, this "ecological model" assumes a complex interaction of individual physiology, family, social environment in communities, cultural influences, and larger social influences on the development of obesity. Interventions based on this model emphasize systematic changes of the factors that promote obesity, including the influence of family, community, and social circumstances (worksite, school, and health care), cultural factors, and the larger social policy environment.[207]

Recommendations

Diabetes and its complications are a significant problem for the black/African American population in Connecticut and nationwide. The causal factors for diabetes, such as obesity, are becoming more prevalent in all age groups and in the whole population. This is a "ticking time bomb" for the current and future adult population.

Addressing metabolic syndrome and its causes will require significant additional prevention-focused support for organizations, that serve youth and adults, such as better primary care access, utilization and focus on the key metabolic syndrome issues in the primary care encounter.

It will also require further public policy development regarding diets available, opportunities for exercise and information about both. These efforts could be focused especially to benefit the black population, which suffers the most from metabolic syndrome diseases and premature death from them.

FOCUS AREA 3 — THE "MEDICAL HOME" CONCEPT: AVOIDABLE EMERGENCY DEPARTMENT (ED) AND HOSPITAL UTILIZATION AND UNDER-USE OF PRIMARY CARE

Findings and Analysis

Health services researchers and policy-makers increasingly realize the importance of a "medical home" — where people can regularly obtain care. Unfortunately for many people, this medical home is often a costly and inappropriate one — the hospital emergency department (ED).

This section examines the self-report data on having a regular source of care, hospitalization for ACSCs, emergency department utilization, linguistic isolation, and preventive care and screening.

Age-adjusted BRFSS survey data for Connecticut reveals that Urban Center adult residents (age 18 and over) are least likely to report a regular source of medical care: only 74.7 percent report such a "medical home." This compares with 80.9 percent in the Manufacturing Centers and values above 87 percent in all of the other HRGs.

These differences are partly due to the low rates for Hispanic residents (66.8 percent in the Urban Centers and 67.2 percent in the Manufacturing Centers) and black residents (77.9 percent in the Urban Centers and 75.4 percent in the Manufacturing Centers). Statewide, white residents are more likely to report having a regular source of medical care (87.5 percent age-adjusted), compared with black and Asian residents (80.7 percent and 79.6 percent, respectively) and Hispanic residents (only 69.7 percent).

These rates to some extent parallel the results for the BRFSS item on who has health insurance: 91 percent of white residents (age-adjusted rate for residents over 18) and 88.5 percent of Asian residents versus 81.6 percent of black residents and 70.9 percent of Hispanic residents. As Table 121 demonstrates, white, black and Hispanic residents having medical homes parallel their having medical insurance, but Asian respondents have a significantly higher rate of health insurance than they have a regular source of care.

TABLE 121: PERCENTAGES OF CONNECTICUT RESIDENTS 18 AND OVER CLAIMING A REGULAR SOURCE OF CARE AND HEALTH INSURANCE, BRFSS SURVEY, 1999-2003

RACE/ETHNICITY GROUP	Percentage with a Medical Home	Percentage with Health Insurance
White, Not Hispanic	87.5	91.0
Black, Not Hispanic	80.7	81.6
Hispanic	69.7	70.9
Asian, Not Hispanic	79.6	88.5

Source: DPH; BRFSS 1999-2003. Note: All race and ethnicity specific rates are age-adjusted.

Hospitalization for Ambulatory Care Sensitive Conditions

OHCA has identified several ambulatory care sensitive conditions for which hospitalization can be avoided through adequate primary care. A high rate of ACSCs is an indicator that disease is not being handled well or at all in the primary care setting, the medical home. This situation could occur for several reasons:

- Patients have inadequate access to primary care or do not use primary care, even when available, until late in the disease process, and then require emergency care and/or hospitalization;
- Poor communication between providers and patients;
- Patients use primary care, but do not follow prescribed medication;
- Inadequate follow-up systems; or
- The underlying condition may be frequent in the population, and even with equal access to and utilization of primary care, the ACSC rate might still be higher (e.g., rates of diabetes for blacks).

Thus, ACSC rates are a "flag" for further investigation, not a conclusion about principal causes. Table 92 in Chapter 7, Health Care Quality, indicates that ACSC rates are highest in the Urban Centers, followed by the Manufacturing Centers, Diverse Suburbs, Mill Towns, Rural Towns, and Wealthy Suburbs, in that order.

ACSC rates are highest for blacks — double the rate for whites — followed by Hispanics and then by whites.

Emergency Department (ED) Utilization

Variation in the rates of ED use can be an indicator of problems with access to primary care or lack of utilization of primary care or poor continuity of care. Although the ED's primary role is immediate treatment and/or stabilization of seriously ill and injured patients, the ED is often used for unscheduled care because of inadequate capacity or underutilization in other parts of the health care system. A study was conducted for the *Data Scan*, based on hospital ED record data from the Connecticut Health Information Management and Exchange (CHIME) database for fiscal years 2002 and 2003 combined. Chapter 7, Health Care Quality, discusses this study — results reproduced in Table 122 — suggesting that Connecticut's urban area populations are most likely to use the hospital ED for treatment of conditions that can be treated more appropriately in a practitioner's office or clinic.

TABLE 122: ANNUALIZED AGE- AND SEX-ADJUSTED EMERGENCY DEPARTMENT VISITS PER 1,000 BY HRG AND RACE/ETHNICITY, FISCAL YEARS 2002-2003

AREA	All	White	Black	Hispanic	Asian
HRG 1 (3)-UC	608.1	423.9	745.4	743.3	117.8
HRG 2 (10)-MC	492.7	394.3	720.8	724.1	76.8
HRG 3 (15)-DS	398.3	379.1	564.3	498.7	126.7

Detailed data and sources are included in Chapter 7, Health Care Quality, and online at www.cthealth.org.

Summary of ACSC and ED Visit Data

There is a significant problem of hospitalization for ACSC and ED utilization for conditions that could be seen in other less expensive, usually more effective settings. This problem is particularly prevalent in the more urbanized settings, and among black and Hispanic residents within these settings, and may be due partly to differential rates of health insurance coverage. However, the differences in insurance rates do not account for the extreme differences in ED utilization. Therefore, fully understanding disparities in the existence or utilization of the medical home is a task still to be accomplished.

Linguistic Isolation

The areas of high ED utilization overlap somewhat with areas of household "linguistic isolation." Among all households, 7.8 percent in the Urban Centers and 4.2 percent in the Manufacturing Centers are Spanish-language linguistically isolated. For all other HRGs, Spanish-language linguistic isolation is negligible. Among households in the Urban Centers, 3.3 percent are linguistically isolated for "other Indo-European language"; among households in Manufacturing Centers, 3.4 percent. In general, Asian-language linguistic isolation is negligible.

The Hispanic population is of particular concern because of higher rates without health insurance, lower rates with a regular source of medical care, and significantly higher rates of linguistic isolation.

Prevention and Screening

Rate disparities are mixed for preventive care and screening, suggesting that although such care is received, it may be in settings other than a "private" medical home. For example, despite differences in health insurance, the BRFSS survey shows negligible differences in self-reported mammogram rates "in the past two years": 74.7 percent for white women over 40, 76.2 percent for black women and 72.3 percent for Hispanic women; the rate for Asian women is not available. Age-adjusted Pap smear rates are 88.5 percent for white women, 85.6 percent for black women, 80.1 percent for Hispanic women, and 76.9 percent for Asian women. Health programs such as the Connecticut State Breast and Cervical Cancer Early Detection program may act to reduce disparities. Chapter 6, Screening and Prevention, includes detailed data for additional screening tests.

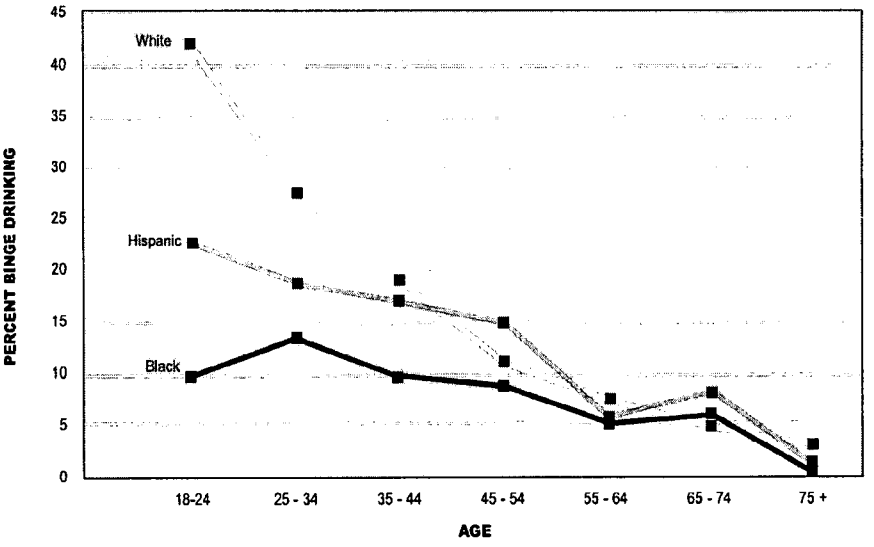
What Is the Value of a Medical Home?

A primary care "medical home" is a place where prevention, screening and guidance regarding causes of metabolic syndrome diseases, problems of alcohol use and abuse, child and youth safety, and other health-related issues can be addressed. Follow-up testing and care can be managed through discussion between practitioners, patients and their families.

But there are cultural and systems constraints to developing a medical home, where time can be taken for these discussions and true patient-provider continuity established. For example, practitioners and patients may have very limited time for dialogue. Language barriers may impede communication. Finally, the meaning of the term "medical home" may be problematic for some immigrants who travel frequently to their "home" countries and who may have multiple medical homes.

Recommendations

Unnecessary ED and hospital utilization are both stressors for the health care system and may result in less effective care. Policies could focus on encouraging greater and earlier use of primary care.



A whole systems approach will be required to reduce avoidable ED and hospital utilization, especially in the Urban and Manufacturing centers. Such an approach would focus on increasing access and comfort with the language and cultural surroundings of the medical home; utilizing the medical home to discuss issues of health risk, chronic disease, and issues of child and youth safety; and promoting adherence to medical regimens prescribed in the primary care setting. In short, a systems approach will need to support and enhance the role of community health centers.

FOCUS AREA 4 — FOCUS ON THE BINGE DRINKING AND SMOKING CULTURE

Findings

Data from the BRFSS surveys demonstrate significant age, race/ethnicity and educational level differences for smoking; considerable race/ethnicity differences were also noted for youth and youth adult binge drinking. These differences are particularly pronounced for the population ages 18-24. Reproduced below is a key figure from Chapter 4, Health Risk and Health-Promoting Behaviors, to illustrate the patterns noted in the data.

FIGURE 29: PERCENTAGE BINGE DRINKING BY AGE AND RACE/ETHNICITY, BRFSS, 1999-2003

Source: Connecticut Department of Public Health (DPH); BRFSS Survey, 1999-2003.

The high school youth population demonstrates significant race/ethnicity differences in smoking and drinking. As in other similar states and nationally, the young white population is more "at-risk" for alcohol abuse and smoking than the black or Hispanic population. One possibility is that this is a cultural phenomenon, buttressed by tobacco and alcohol industry marketing.

Recommendations

Changing binge drinking and smoking will require a broad effort to change both the level of information about the signs and consequences of alcohol abuse and tobacco use, changing cultural norms regarding alcohol and tobacco use, and the penalties for alcohol abuse, e.g., drunken driving and teen access to tobacco.

Additional programming in this area could be partly funded by greater disbursements from tobacco settlement money. Connecticut is currently far below the Centers for Disease Control and Prevention (CDC) minimum recommendation for tobacco prevention funding. In FY 2007, Connecticut was at 9.4 percent of the CDC recommendation, 36th of 45 states reporting.[208]

FOCUS AREA 5 — YOUTH RISKS AND OPPORTUNITIES

Findings and Analysis — Selected Indictors

Numerous investigations have examined youth risk behavior from the sociological, behavioral and even brain development perspectives. While the assumption had been that adolescent brain development was, like adolescence itself, a transitional stage between childhood and adulthood, research now indicates that changes in different areas of the brain play critical roles in memory, voluntary motor behavior, impulse control, decision making, planning, and other higher cognitive functions.[209]

Several measurable aspects of youth- and young-adult safety and behavior were selected as "indicator variables," including: child abuse; Connecticut Academic Performance Test (CAPT) participation and passing rates; high school graduation; school suspension and expulsion; sexually transmitted diseases; teen births; seat belt use; and bicycle helmet use, all presented in Chapter 4, Health Risk and Health-Promoting Behaviors. Also, implications of the statistics on membership in adult-sponsored, youth-promoting out-of-school organizations were presented in Chapter 3, Connecticut Community Profile.

Sexually Transmitted Disease and Teen Births

There are marked disparities in sexual risk-taking behavior among youth and young adults, as indicated in the sexually transmitted disease (STD) incidence rates and teen birth statistics.

Overall, the rate of STDs for black, non-Hispanic persons age 15 to 34 is 39.3 per 1,000; for Hispanics, 15.1 per 1,000; for white non-Hispanic 2.2 per 1,000; and for Asian non-Hispanic, 1.9 per 1,000. The rates are highest for black non-Hispanic persons in the Urban Centers — 53.5 per 1,000. In general, STD incidence rates peak in the late teens and decline after age 20. Further details are available in Chapter 4, Health Risk and Health-Promoting Behaviors.

Teen birth rates also show a marked disparity. Although the overall rate for Connecticut is 24.0 per 1,000, the rate climbs to 50.4 for black teens statewide, and 71.4 per 1,000 for Hispanic teens statewide. Within this group, Puerto Rican teens have an 84.8 per 1,000 rate, while non-Puerto Rican Hispanic teens have a rate of 44.3 per 1,000. Teen birth rates are generally elevated for all race and ethnicity groups in the Urban and Manufacturing centers. The highest rate is that of Puerto Rican Hispanic teens in the Urban Centers: 90.8 per 1,000.

Youth Seat Belt and Bicycle Helmet Use

Another indicator of risk taking is vehicle use without adequate protection. There are also marked disparities in these indicators. According to the 2005 Connecticut High School Survey (available at: http://www.dph.state.ct.us/PB/HISR/CSHS.htm) 73.1 percent of white male students statewide used a seat belt "all or most of the time," but only 46.1 percent of black male students and 56.0 percent of Hispanic male students did so. Rates for female students were higher for each group: 77.3 percent for white female students, 67.9 percent of black female students and 59.0 percent of Hispanic female students.

Self-reported bicycle helmet use, for students riding a bike during the past 12 months, was significantly lower for black (92.3 percent reporting never or rarely used) and Hispanic (89.9 percent) than for white students (70.6 percent). Similar race and ethnicity differences are noted on adult reports of their children's use of bicycle helmets as shown in Table 46. The rate of helmet use for all race and ethnicity groups is markedly too low.

Child Abuse

Abuse is a health risk for a significant number of Connecticut children. Reports of cases to Connecticut Department of Children and Families (DCF) and ED visits offer two types of data on the problem of child abuse. There is a large discrepancy between reports to DSS and ED visits because many more cases are reported to DCF than are coded in emergency departments. But the HRG patterns are similar, as they are for all age-adjusted ED-reported abuse rates.

Female children appear to be more at risk than male children. All children need better protection, especially those in the Urban Centers, Manufacturing Centers, Diverse Suburbs, and Mill Towns, as shown in Table 41 and Table 42 in Chapter 4, Health Risk and Health-Promoting Behaviors. The highest rates of DSS-reported abuse are for black and Hispanic youth.

Youth-Serving Organizations

Many community resources are available to help prevent health risks and poor health outcomes. These can include active out-of-school programs, such as Scouts and youth soccer and other sports.

Data on soccer and scouting participation by both boys and girls show a markedly lower rate of participation in the Urban and Manufacturing centers than in the state as a whole. This becomes problematic when data also show that other types of adult-sponsored activities for youth do not have high enough participation rates to make up the difference. For example, Boys and Girls Clubs serve primarily urban youth, yet they are estimated to serve fewer than one in 10 (8.8 percent) of all youth in the Urban Centers.

The Jack and Jill Clubs, an important mothers' volunteer program geared toward black and multiracial children and youth, have a membership estimated at 456 children in Connecticut, but only half of these members may reside in the Urban or Manufacturing centers. Thus, the vast majority of black and Hispanic children and youth appear not to be adequately involved in adult-sponsored, non-church-related organizations. The number involved in church-sponsored organizations is not known.

Recommendation

Broad initiatives on child and youth risk taking and safety could be focused especially on the Urban and Manufacturing centers, and on black and Hispanic children and youth, who are most at risk regarding a variety of safety and risk issues. These initiatives could include making available well-focused, out-of-school health promoting activities to youth in the neighborhoods in the Urban and Manufacturing centers, where such activities currently neither enroll many school-age children and youth nor attract sufficient adult volunteers. In addition, better data on youth out-of-school participation is a vital need.

FOCUS AREA 6 — IMPROVE THE HEALTH DATA SYSTEM

In preparing the *Data Scan*, the author had an opportunity to evaluate some aspects of the Connecticut "data system." It is actually not a system, but a series of separate "pots" of data in varied formats, each with its own strengths and weaknesses. This section is organized as a series of findings and recommendations.

Data Access

Finding

There are problems with the data access and coordination "infrastructure" in Connecticut that have been previously studied. Each request for other-than-standard web-based reports must be fulfilled separately by Connecticut state agency personnel — a time-consuming and costly process. Web-based reports are frequently presented only in portable document format (PDF) format, which makes secondary analyses and display of data more difficult.

Recommendation

A query-driven system would make the data more widely and easily available. A hypothesized pattern of health disparities would be less conjecture and more clearly demonstrated or refuted. More fine-tuned analyses below the state level — such as by HRG — would be possible and would not require state personnel to fulfill individual data requests.

Departmental Web Sites

Finding

Connecticut does not have a "one-stop shopping place" for broad community health data, in contrast to other states such as Florida, Utah, Missouri, and Massachusetts. At best, each Connecticut state department operates a separate "silo" for data. Each department's data is in a different format, with different and often inadequate access and search procedures. This produces great difficulty in searching for data and developing a broad picture of community health.

Recommendation

Provide a single community health web "portal" through which data and information about that data can be shared with the public. This will ease access problems, encourage standardization of procedures and data formats, and assist in more fruitful data search strategies. Encourage state agencies to take part in this "one-stop" effort.

Mapping

Finding

There is no accessible mapping capability for community health data in Connecticut. By comparison, in Massachusetts' Mass-CHIP system and in several other state systems data can be queried, graphed and mapped. This allows for great flexibility in analysis and presentation. It makes data available quickly to concerned citizens and policy-makers, as they need to analyze and display the information.

Recommendation

Encourage the inclusion of a mapping option in a query-based data system.

Data Delays

Finding

A previous analysis of the state of community health data in Connecticut indicated a number of structural weaknesses, culminating in delays in the release of data.[210]

State agencies and the public may not have a shared sense of what is reasonable. Frustration borne out of unshared expectations may occur because of time lags between when central authorities receive data and perform the necessary quality control on the data before publication. In addition, resource and infrastructure issues may lead to delay.

Recommendation

Interested organizations could work with state policy-makers to establish clear policies and standards based on reasonable expectations regarding the collection and release of data. Since timetables will be specific to different types of data, the public data consumer would further be helped by having lists of data items and realistic expectations of the time required to release data. For example, three years may be reasonable for Cancer Registry data to be issued in report format, but it may be unreasonably long for the reporting of infectious disease data. In addition, as practiced at the federal level, "preliminary data" could be released early and "final data" later in time.

Meta Data — Documentation about Data

Finding

There is a serious lack of "meta-data"— documentation about the data themselves — on the datasets accessed from many Connecticut agencies. For example, a particular dataset might use race and ethnicity as a variable to "group" health observations. Meta-data would be information about how race and ethnicity are defined for that particular dataset. For many indicators, the author had to piece together meta-data in preparing this report.

Recommendation

Support the establishment of a standard for meta-data with the clear expectation that all state agency reports will follow it. This would be easy to do when creating new datasets because much less labor is required to create meta-data as new datasets are being created — rather than to find the information at a much later date.

Youth Data

Finding

Despite the recognized importance of out-of-school program participation, there is neither a comprehensive dataset on this key indicator nor a way to systematically estimate it. There has also been a serious weakness in the collection of YRBS data in the recent past. For several iterations of the YRBS, data were not collected or the CDC has not "weighted" the Connecticut data, due apparently to a lower than acceptable response rate. Data collection for the 2005 YRBS was sufficient for CDC weighting — allowing for statistical inferences from the data.

Recommendation

The Connecticut departments of Public Health and Education could investigate and help strengthen the capacity to collect youth data. One method used in Massachusetts is to add items to that state's equivalent of the Connecticut Academic Performance Test (CAPT), asking about the type and frequency of out-of-school program participation by each child.

The departments could choose noncontroversial items about students' after-school activities, including homework, clubs, sports, and TV watching and make them an addendum to the CAPT testing, so that universal coverage for the relevant grades could be obtained. Doing so will allow for population-based estimates by school district, by HRG, and/or by race and ethnicity group. The data would also be useful to individuals districts in diagnosing student performance.

Health Observations

Finding

Observation-based health data are lacking in many areas — such as youth safety that includes seat belt use; bicycle helmet use; the prevalence of violence promoting graffiti in a neighborhood; the availability, conditions, use of public spaces for exercise; and the amount of smoking on school property and at school-sponsored events. Observation would be useful, but expensive, if done in the traditional manner — hiring observers. There appears to be no current capability to collect such data on a systematic basis.

Recommendation

Support community-based research partnerships such as those pioneered by the Youth Action Research Institute of Hartford's Institute for Community Research[211] to work with public school students and other youth to collect community-oriented data as part of a larger statewide project.

This kind of data collection and analysis falls completely within the requirements of the Connecticut Mathematics Curriculum Frameworks Content Standards and Expected Performances. For example, one framework requires collecting, organizing, and displaying data help to analyze information and make reasonable predictions and informed decisions.[212]

With its connection to required school work, this innovative strategy offers the advantages of:

- Collecting needed health data;
- Encouraging student interest in learning about their communities in a prosocial way and taking action based on their findings;
- Raising students' interest in their own health; and
- Fulfilling school curriculum requirements.

Partnerships among community agencies, universities, and schools would "improve teachers' and students' understanding of sampling, surveys, and observational strategies,"[213] as well as obtain vital data for health assessments.

Race and Ethnicity Categories

Finding

The broad-brush approach to race and ethnicity identification misses significant variation. For example, in this report the Puerto Rican Hispanic teen birth rate appears to be more than double the non-Puerto Rican Hispanic teen birth rate. Yet most datasets do not include this subgroup code. There may be similar disparities within broad race and ethnicity groups, such as between Chinese, Vietnamese and Cambodian Asians. Given most current practices in subgroup data collection and reporting, there is no way to verify whether these subgroups are at particular risk. Finally, most datasets do not include biracial reporting categories. Yet, biracial individuals on many indicators have different health profiles than either of their "monoracial" components.[o, 214] Biracial individuals are becoming numerically more important as residents increasingly insist on reflecting all parts of their heritages and as the rate of biracial marriages increases.

Recommendation

Encourage agencies, wherever possible, to obtain more specific race and ethnicity identification, including biracial identification, consistent with federal Office of Management and Budget (OMB) Directive 15 (1997 Revision) and U.S. Census Bureau practice, and make the results available in more fine-tuned analyses. Doing so will permit better targeting of interventions.

Health Care Quality

Finding

There are significant problems in conceptualizing and operationalizing health care quality data in Connecticut. The current method of obtaining hospital adverse event data leads to what appear to be significant underestimates. There also are no broad and agreed-upon standards for "adjusting" data for patient acuity.

Recommendation

Support development of an agreed-upon overall quality "index" that would help the public to know whether or not health care quality is getting better. Subsections of the index could indicate which sectors are leading and which are lagging in improvement. The index also could be constructed to reveal disparities in the quality of care, with adequate controls for appropriateness of care, patient choice and co-morbidities. Given anticipated difficulties, this could be a long-term project.

Mental Health Data

Finding

The mental health data system remains problematic despite efforts to improve it and to implement the Center for Mental Health Services (CMHS) Uniform Reporting System (URS) dataset and standards. Some data in the federal submissions under URS seem contradictory or beg further explanation. But the format of the reporting tables does not contain enough helpful explanatory documentation (meta-data).

There is a fragmentation of data reporting, lack of online data capability, and a lack of readily accessible information about the agencies' data definitions and the connection of particular datasets to specific programs. Information exists in the historical memories of individual staff but is not documented adequately to guide outside researchers.

Recommendation

Support the development of better organized mental health data — and make the data and information documentation about it available online to promote an educated citizenry about this important area.

A NOTE ABOUT ADDITIONAL ISSUES

Many important issues are not a focus of this report's recommendations. This is generally because, although there may be disparities, there are not clear science-based interventions of proven efficacy for reducing these rates or disparities.

This report did not focus specifically on investigating oral health and mental health due to Connecticut Health Foundation's (CHF) current investments in these areas. Some data were obtained that are pertinent to these issues and are reported here.

Mental Health

The BRFSS indicates that 8.2 percent of Connecticut residents 18 and over self-report poor mental health 15 or more days in the past month. There is little variation by HRG on this indicator: 10.0 percent (age-adjusted) for the Urban Centers; 8.6 percent for the Manufacturing Centers; 9.2 percent for the Diverse Suburbs; 6.1 percent for the Wealthy Suburbs; 8.6 percent for the Mill Towns; and 7.0 percent for the Rural Towns. There do not appear to be significant race- and ethnicity-specific differences in mental health status, except for Asians, whose statewide rate — 4.6 percent — is significantly lower on the poor mental health indicator.

The federal government publishes estimates of adults' and youths' need for mental health treatment. The 2004 Connecticut estimate for "serious mental illness" was 143,493.

Recent national data indicate that, on interview, 6.3 percent of parents thought that a son in the age range, 4 to 17 years old had "definite or severe difficulties with emotions, concentration, behavior, or being able to get along with others." This was true for only 3.3 percent of girls in the same age range.

The data show statistically significant race and ethnicity differences: 8.3 percent of black boys were assessed by a parent to have such difficulties, as compared with 6.6 percent of white boys, and 4.7 percent of Hispanic or Latino boys.

The comparable — but not statistically different — rates for girls the same age were: 3.8 percent of white girls, 2.7 percent of black girls, and 2.6 percent of Hispanic or Latino girls.

The family structure "mother present, no father in the household" was also associated with higher rates of perceived difficulties.[215]

See Appendix M for further discussion of mental health in Connecticut and www.cthealth.org for selected data.

Oral Health

Overall, 79.2 percent of Connecticut residents reported a "past year" dental visit in the previous year. This rate varies by HRG in that only 71.8 percent of the Urban Center residents 18 and over reported a visit, 73.9 percent of Manufacturing Center residents, 77.3 percent of Diverse Suburbs residents, 85.8 percent of Wealthy Suburb residents, 80.5 percent of Mill Town residents, and 83.6 percent of Rural Town residents.

Dental visits varied significantly by race and ethnicity: 81.7 percent of white residents, 72.2 percent of Asian residents, 66.5 percent of black residents, and 65.8 percent of Hispanic residents.

There are no overall data about oral health for children in Connecticut. Recent 2005 data prepared by Connecticut Voices for Children regarding children 3 to 19 continuously enrolled in HUSKY A, Connecticut's Medicaid managed care program, indicate that approximately 41 percent of the children involved in that program received preventive oral health care, and 22 percent received treatment. Both of these rates were virtually unchanged from 2004.

The child's age was the chief variable in preventive care and treatment, from a low of 38 percent in the 3- to 5-year-old age group to 51 percent in the 6- to 8-year-old group, 49 percent between 9 and 11 years old, 42 percent age 12-14, and 28 percent age 15-19. These percentages were virtually unchanged from 2004.

Hispanic children in HUSKY A had the highest rate of preventive care (44 percent), while black and white children each had a 39 percent rate. "Other" children had a 44 percent rate. These rates were unchanged from 2004. Treatment rates showed a slightly different pattern: 26 percent of "other" children were treated, followed by 23 percent of Hispanic children, 21 percent of white children, and 20 percent of black children.[216]

Additional data obtained from Connecticut Voices for Children have demonstrated expected differences by HRG in the percentage of children enrolled in HUSKY A, but only slight differences among HRGs in the percentages of participation of HUSKY A enrollees in dental care.[217]

TABLE 123: CHILDREN AGE 3-19 CONTINUOUSLY ENROLLED IN HUSKY A, 2004

OVERALL COMMENT ON THE FINDINGS AND RECOMMENDATIONS

Some of the findings and recommendations in this report may be more difficult than others to embrace and implement. This is partly because they locate the problem at all levels of the "system": state, health provider, corporate, community, family, peer group and individual. Each level may require work for the health outcome to change. Changing cultural norms will be important as well.

Focusing on diabetes, for example, and more generally on the metabolic syndrome, will require changes in how primary care providers counsel patients about issues of obesity, diet and exercise. It will require changes in how parents understand and implement their responsibilities regarding their children's diet, exercise and TV-watching.

Focusing on metabolic syndrome diseases will also require changing community-specific cultural norms about food and exercise, as well as limiting the "selling" of residents and their children on unhealthy diets. The state will need to expand its capacity to collect population-based data on children and youth to make better estimates of the extent of their out-of-school activities and risk behaviors.

The effort will require policy changes — such as school bus and school lunch policies — and providing more opportunities and support for safe walking, rollerblading and biking to school, to work and for recreation. Transportation policy has a significant role to play.

In summary, a systems view will require supporting investigations and action in each part of the causal chain to improve health outcomes for current and future residents of Connecticut.

Explanation of Symbols:
'****' - The median falls in the lowest interval or upper interval of an open-ended distribution. A statistical test is not appropriate.
'*****' - The estimate is controlled. A statistical test for sampling variability is not appropriate.
'N' - Data for this geographic area cannot be displayed because the number of sample cases is too small.
'(X)' - The value is not applicable or not available.

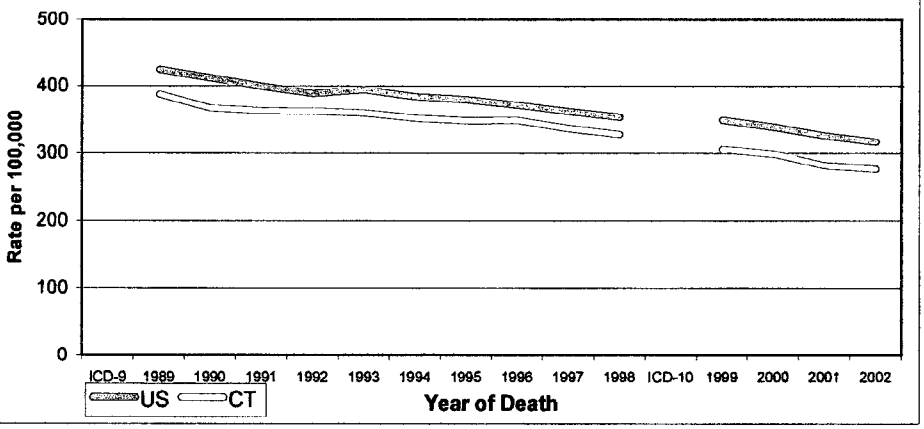
INTRODUCTION

Cardiovascular diseases involve the body's vascular system, which is responsible for supplying oxygen and nutrients to the body's organs and cells. The most common forms of cardiovascular disease are coronary heart disease and cerebrovascular disease. Essential hypertension, congestive heart failure, and atherosclerosis are other common cardiovascular diseases. Cardiovascular diseases (CVD) are of great public health concern because more than one-third of all deaths in the United States and Connecticut are due to CVD and because prevention efforts have shown such great potential in reducing CVD morbidity, mortality, and disability.[1]

Coronary heart disease and cerebrovascular disease deaths have shown decreasing trends over time in the United States and Connecticut.[2] Despite advances in treatment, however, the number of congestive heart failure deaths has increased steadily in Connecticut and the United States most likely because people are surviving heart attacks experienced earlier in life.[3] Approximately 59% of all congestive heart failure deaths in Connecticut occur to persons aged 85 or older. In contrast, only 39% of all coronary heart disease deaths and 46% of all cerebrovascular disease deaths occur in persons 85 and older.[4]

THE BURDEN OF CARDIOVASCULAR DISEASE IN CONNECTICUT

Mortality



Cardiovascular diseases accounted for 11,365 Connecticut resident deaths in 2002, or about 38% of all deaths for the period.[5] In contrast, cancer deaths comprised 24%, chronic lower respiratory disease comprised 5%, unintentional injuries comprised 4%, and diabetes comprised 2% of all Connecticut resident deaths in 2002 (Table 1).

Table 1. CONNECTICUT RESIDENT DEATHS – 2002

- 30,055 Deaths from All Causes
- 11,365 Cardiovascular Disease Deaths
- 7,130 Cancer Deaths
- 1,452 Chronic Lower Respiratory Disease Deaths
- 1,155 Unintentional Injury Deaths
- 674 Diabetes Deaths

Figure 2. Cardiovascular Age-adjusted Mortality Rates, Connecticut & the United States

Sources: Centers for Disease Control and Prevention, 2005; Connecticut Department of Public Health, 2005. Note: Rates are adjusted to the 2000 US standard million population. Classification includes deaths with ICD-9 codes: 390-459.9 (1989 to 1998); ICD-10 codes: I00, I78.9 (1999 to 2002).

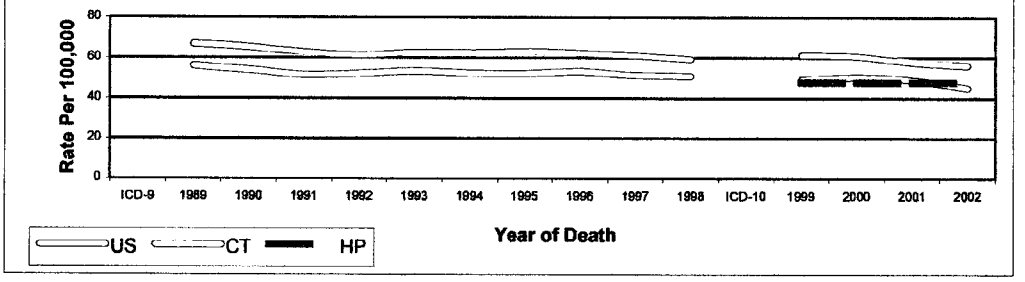

Figure 3. Coronary Heart Disease Age-adjusted Mortality Rates, Connecticut, United States & Healthy People 2010 Target

Sources: Centers for Disease Control and Prevention, 2005; Connecticut Department of Public Health, 2005. Note: Rates are adjusted to the 2000 US standard million population. Classification includes deaths with ICD-9 codes: 402,410-414, 429.2 (1989 to 1998); ICD-10 codes: I11, I20-25 (1999 to 2002).

Between 1989 and 1998 age-adjusted stroke mortality rates did not change significantly for the Connecticut population as a whole. Connecticut death rates from stroke have been consistently lower than those of the U.S., and very close to the *Healthy People 2010* target of 48 per 100,000 population (Figure 4).[10,11]

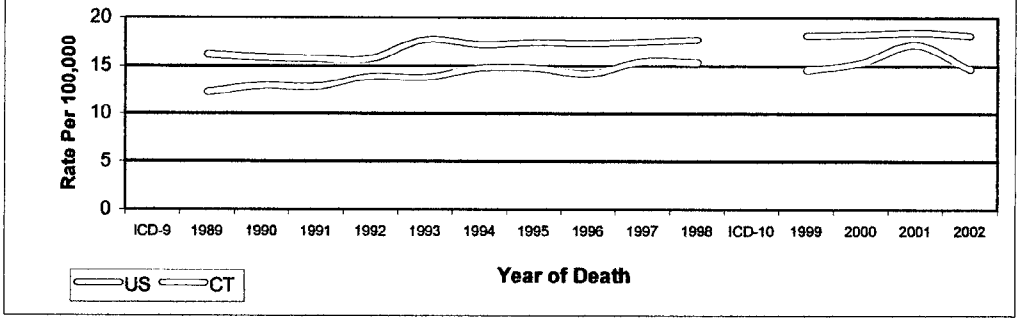

Figure 4. Stroke Age-adjusted Mortality Rates, Connecticut, United States & Healthy People 2010 Target

Sources: Centers for Disease Control and Prevention, 2005; Connecticut Department of Public Health, 2005.
Note: Rates are adjusted to the 2000 US standard million population. Classification includes deaths with ICD-9 codes: 430-438 (1989 to 1998); ICD-10 codes: I60-69 (1999 to 2002).

Between 1989 and 1998 congestive heart failure (CHF) age-adjusted mortality rates increased significantly for the Connecticut population as a whole ($p < .01$). There is no *Healthy People 2010* target for congestive heart failure (Figure 5).

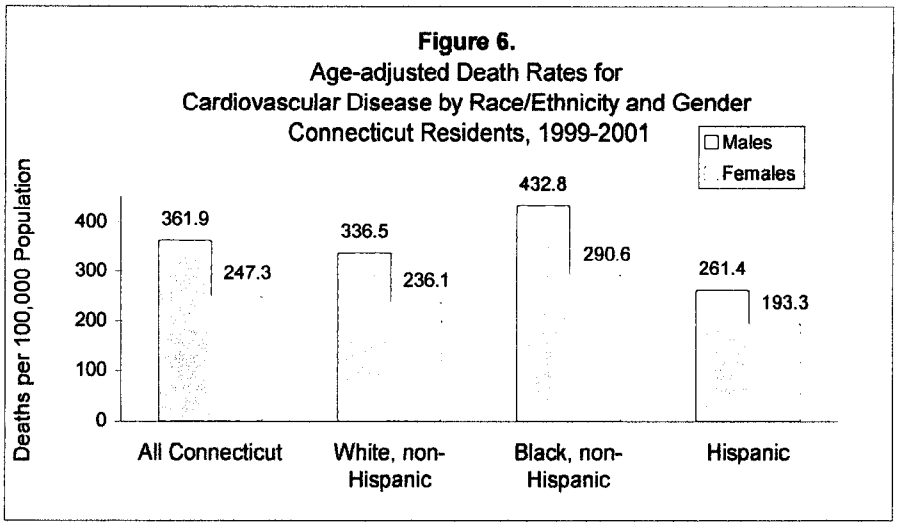
Figure 5. Congestive Heart Failure Age-adjusted Mortality Rates, Connecticut and the United States

Sources: Centers for Disease Control and Prevention, 2005; Connecticut Department of Public Health, 2005.
Note: Rates are adjusted to the 2000 US standard million population. Classification includes deaths with ICD-9 code: 428.0 (1989 to 1998); ICD-10 codes: I50.0 (1999 to 2002).

Mortality by Gender

Approximately 55% of all Connecticut resident CVD deaths in 2002 were female. While more females than males die from CVD in Connecticut, males have higher age-adjusted mortality rates (Table 2).[12] In 2002, Connecticut males had a 45% higher death rate due to CVD compared with females and a 60% higher death rate due to CHD ($p < .001$ for both comparisons). Connecticut males and females had equivalent rates of death due to stroke and congestive heart failure in 2002.

Table 2. Cardiovascular Diseases Deaths and Age-adjusted Mortality Rates (AAMR) per 100,000 population - Connecticut Residents, 2002

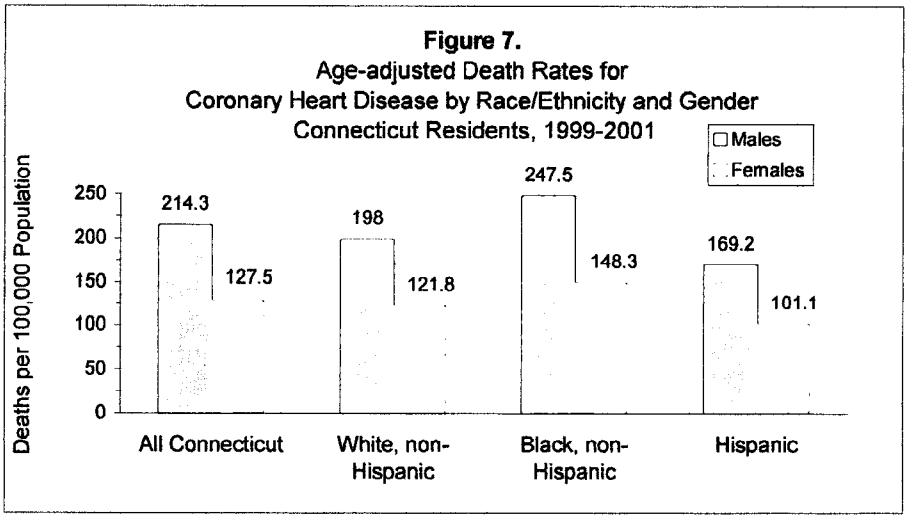


Cause of Death	All		Male		Female	
	Deaths	AAMR	Deaths	AAMR	Deaths	AAMR
All Cardiovascular Diseases	11,365	277.8	5,139	337.0	6,226	231.7
Coronary Heart Disease	6,246	153.3	2,998	195.3	3,248	120.2
Stroke	1,867	45.2	684	45.2	1,183	44.3
Congestive Heart Failure	629	14.7	240	16.6	389	13.4

Source: Connecticut Department of Public Health, Vital Records Mortality Files, 2005.

Mortality by Race/Ethnicity and Gender

Cardiovascular Disease

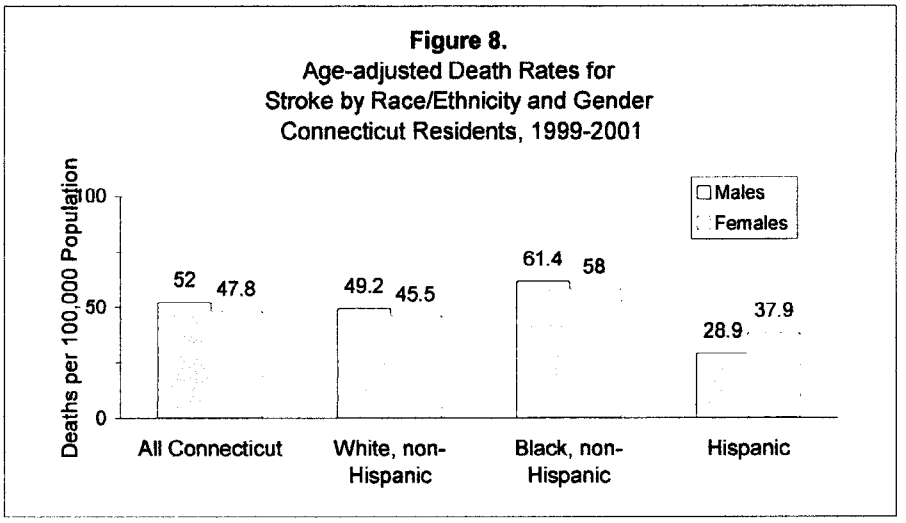


Age-adjusted CVD death rates differ by race, ethnicity and gender with Black (non-Hispanic) males and females having significantly higher CVD death rates compared with White (non-Hispanic) males and females, respectively ($p < .001$ for both comparisons). Hispanic males and females have significantly lower death rates due to CVD than do White males and females ($p<.01$ for both comparisons) [Figure 6].[13] CVD death rates declined significantly for White and Black males and White females between 1989-91 and 1996-98 ($p < .01$ for all comparisons). CVD death rates did not change significantly for other subpopulation groups during this time period.[14]

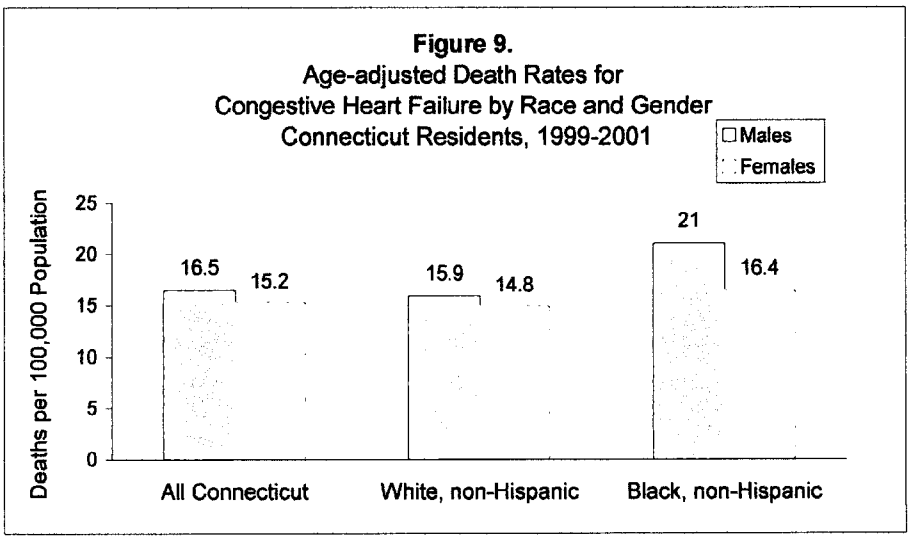
Source: Connecticut Department of Public Health, Vital Records Mortality Files, 2005.

Coronary Heart Disease

Coronary heart disease death rates differ by race, ethnicity, and gender with Black (non-Hispanic) males and females having significantly higher CHD death rates compared with White (non-Hispanic) males and females, respectively ($p < .01$ for both comparisons). White and Hispanic males do not have significantly different death rates due to CHD. White females have significantly higher CHD death rates compared with Hispanic females ($p < .05$) [Figure 7].[15] CHD death rates declined significantly among White males and females between 1989-91 and 1996-98 ($p < .001$), while CHD death rates did not change significantly for other subpopulation groups during this time period.[16]



Source: Connecticut Department of Public Health, Vital Records Mortality Files, 2005.



Stroke

Age-adjusted stroke death rates differ somewhat by race, ethnicity and gender. Stroke death rates (1999-2001) of Black and White males are not significantly different; however, they are significantly higher than Hispanic male stroke death rates ($p < .01$ for both comparisons). Black females have significantly higher age-adjusted stroke death rates compared with White and Hispanic females ($p < .05$ for both comparisons). Age-adjusted stroke death rates of White and Hispanic females are not significantly different (Figure 8).[17] Age-adjusted stroke death rates declined significantly for Black males between 1989-91 and 1996-98 ($p < .05$), but did not change significantly for other subpopulation groups during this time period.[18]

Congestive Heart Failure

Age-adjusted congestive heart failure (CHF) death rates do not differ significantly by race and gender (Figure 9). There were too few deaths among Connecticut Hispanic residents (N=30) in the period 1999-2001 to calculate stable mortality rate estimates. Age-adjusted CHF death rates increased significantly for all Connecticut residents between 1989-91 and 1996-98 ($p<.01$); the increase was significant for Black and White females but not for other subpopulation groups during this time period.[19]

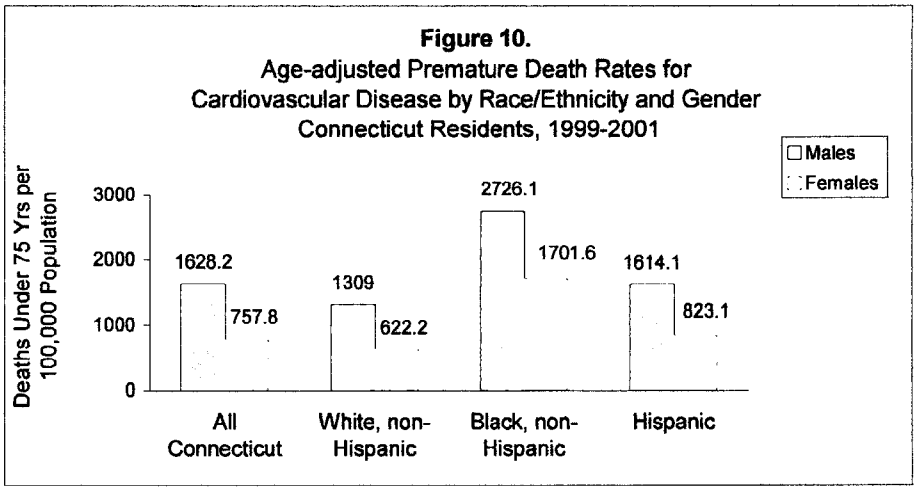
0573
09/15/08



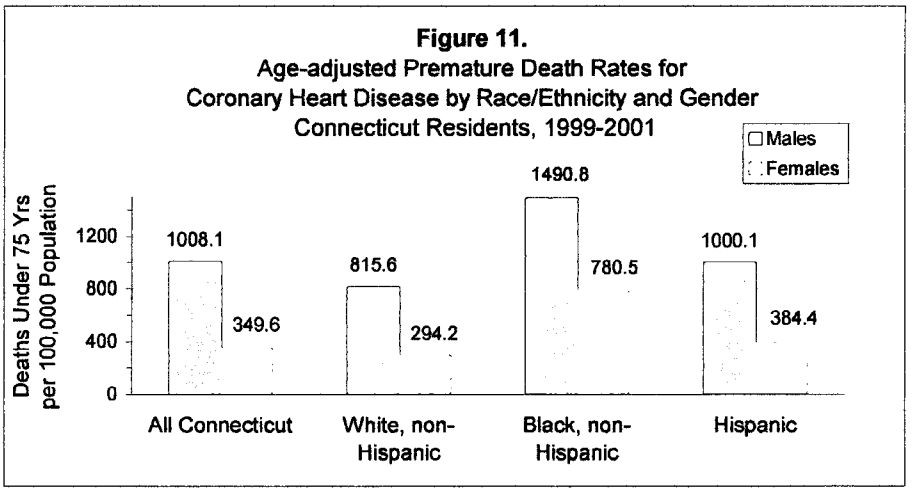
Premature Mortality by Race/Ethnicity and Gender

Premature mortality, defined as the "years of potential life lost before age 75," emphasizes deaths that occur at younger ages. For example, a person who dies at age 45 is considered to have lost 30 years of life, and a person who dies at 70 is considered to have lost 5 years of life.[20]

Cardiovascular Disease

Black (non-Hispanic) residents have significantly higher age-adjusted premature CVD mortality rates (under 75 years) compared with White (non-Hispanic) and Hispanic residents ($p < .001$) [1999-2001 data](Figure 10).[21] CVD time-trend analyses show that age-adjusted premature CVD death rates declined significantly for the entire population ($p < .001$) between 1989-91 and 1996-98. CVD death rates declined significantly for White and Black males and White females ($p < .01$ for all comparisons), but did not change significantly for other subpopulation groups during this time period.[22]

Figure 10.
Age-adjusted Premature Death Rates for
Cardiovascular Disease by Race/Ethnicity and Gender
Connecticut Residents, 1999-2001



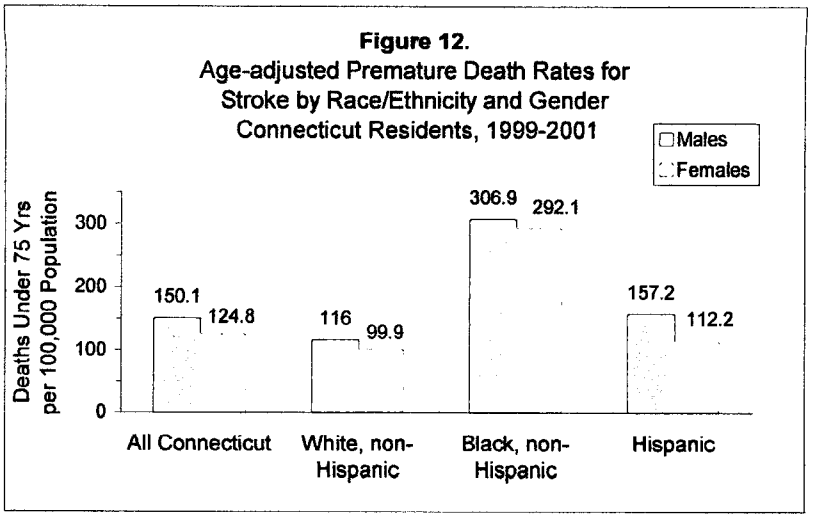
Source: Connecticut Department of Public Health, Vital Records Mortality Files, 2005.

Coronary Heart Disease

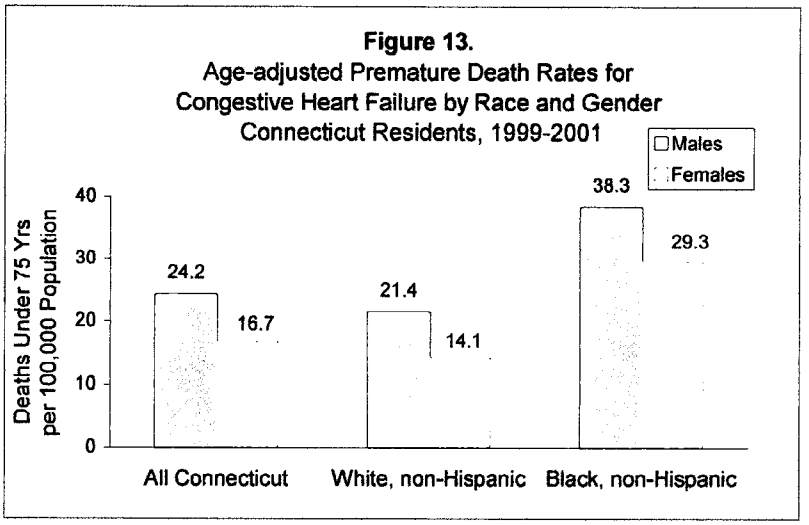
Black (non-Hispanic) residents have significantly higher age-adjusted premature coronary heart disease (CHD) mortality rates (under 75 years) compared with White (non-Hispanic) and Hispanic residents (1999-2001 data). Age-adjusted premature CHD mortality rates of White and Hispanic residents are not significantly different (Figure 11).[23] CHD time-trend analyses show that age-adjusted premature CHD death rates declined significantly for White males and females between 1989-91 and 1996-98, but did not change significantly for other subpopulation groups during this time period.[24]

0574
09/15/08

Source: Connecticut Department of Public Health, Vital Records Mortality Files, 2005.



Stroke



Age-adjusted premature stroke death rates differ somewhat by race, ethnicity and gender. Black males have significantly higher premature stroke death rates (1999-2001 data) than do White and Hispanic males ($p < .01$ for both comparisons). Age-adjusted premature stroke death rates of White and Hispanic males are not significantly different. Black females have significantly higher premature stroke death rates compared with White and Hispanic females ($p < .01$ for both comparisons). Age-adjusted premature stroke death rates of White and Hispanic females are not significantly different (Figure 12).[25] Time trend analyses show that age-adjusted premature stroke death rates declined significantly among Black males between 1989-91 and 1996-98, but did not change significantly for other subpopulation groups during this time period.[26]

Congestive Heart Failure

Age-adjusted premature CHF mortality rates (under 75 years) of White and Black residents are not significantly different (1999-2001 data).[27] There were insufficient numbers of CHF deaths among Hispanics to calculate reliable premature mortality rates (Figure 13).

Age-adjusted premature CHF death rates increased significantly for the entire population ($p < .01$) between 1989-91 and 1996-98. This increase was significant for White females ($p < .001$) and Black females ($p<.05$), but not for other subpopulation groups during this time period.[28]

Source for Figures 12 and 13: Connecticut Department of Public Health, Vital Records Mortality Files, 2005.

0576
09/15/08

Morbidity

During 2002, there were 62,174 discharges from Connecticut hospitals for all cardiovascular diseases. This represents 20% of all hospital discharges (excluding pregnancy and childbirth related discharges) and 23% of all hospital billing charges in the state. Approximately 34% of all cardiovascular disease discharges were due to coronary heart disease (CHD), 12% were for stroke discharges, and 16% were for discharges with congestive heart failure. The median length of stay for CHD, stroke, and congestive heart failure was three, four, and four days, respectively. The median length of stay for all hospital discharges in Connecticut during the same period was three days. [29]

Hospitalization Rates by Gender

Connecticut males have significantly higher rates of hospitalizations for all cardiovascular diseases, coronary heart disease, stroke, and congestive heart failure compared with Connecticut females ($p < .05$). More females than males, however, are hospitalized for stroke and congestive heart failure [Table 3].[30]

Table 3. Cardiovascular Diseases Hospitalizations and Age-adjusted Hospitalization Rates (AAHR) per 100,000 population - Connecticut Residents by Gender, 2002

Cause of Death	All		Male		Female	
	Number	AAHR	Number	AAHR	Number	AAHR
All Cardiovascular Diseases	62,174	1,630.2	33,097	2,059.3	29,077	1,289.1
Coronary Heart Disease	21,178	561.2	12,954	791.4	8,224	372.7
Stroke	7,618	198.3	3,618	227.7	4,000	174.5
Congestive Heart Failure	10,076	255.9	4,656	299.9	5,420	224.8

Source: Connecticut Department of Public Health, Connecticut Hospital Discharge Abstract and Billing Data Base, 2005.

Hospitalization Rates by Race and Ethnicity

Black (non-Hispanic) Connecticut residents have significantly higher rates of hospitalizations than both White (non-Hispanic) and Hispanic residents for all cardiovascular diseases, coronary heart disease, stroke, and congestive heart failure ($p < .05$ for all comparisons). Hispanic residents have significantly higher rates of hospitalizations than Whites for all cardiovascular diseases and for congestive heart failure; however, Hispanic-White differences in hospitalizations for CHD and stroke are not significantly different (Table 4).[31]

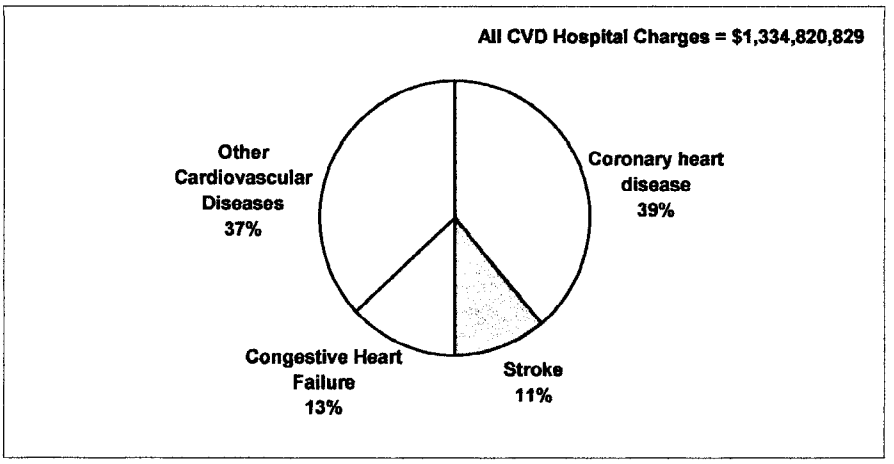
Coronary Heart Disease Treatment: Revascularization Procedures

Surgical interventions—coronary artery bypass graft surgery (bypass surgery or CABG), valvular surgery, and percutaneous transluminal coronary angioplasty (angioplasty or PTCA)—are commonly used to treat coronary artery disease. These revascularization procedures provide a new, additional, or augmented blood supply to the heart. Use of these procedures nationally and in Connecticut has increased with the development of this technology.[32] In 2002, there were 5,812 hospital discharges receiving PTCA, 3,000 receiving CABG, and 1,178 receiving valvular surgery in Connecticut. Revascularization procedures can be effective, but costly. In 2002, median charges for PTCA, CABG, and valvular surgery were $22,200, $40,776, and $53,869 for Connecticut residents.[33]



Economic Costs

The estimated national annual cost for the medical management of cardiovascular disease is $403.1 billion in 2006, or $1,352 per person.[34] This estimate includes direct medical costs and indirect costs associated with lost productivity from illness and death. Both heart disease and stroke can accrue enormous indirect costs. They are major causes of disability and the ability to live independently, and they can severely impact the quality of life for individuals and families. Assuming that per person costs are the same in Connecticut as they are nationwide, the estimated economic burden of CVD in our state is about $4.7 billion. A large portion of these costs is attributable to inpatient hospitalizations.

Total Connecticut CVD hospital charges in 2002 were about $1.3 billion, with a median charge of $13,500 (Figure 14). About 39% of total CVD hospitalization charges were for CHD, 11% were for stroke, and 13% were for congestive heart failure hospitalizations. Median hospital charges were $17,662 for coronary heart disease, $12,013 for stroke, and $11,248 for congestive heart failure. In contrast, the median charge for all hospital discharges in Connecticut was $8,451.[35]

Risk Factors for Cardiovascular Diseases

Risk factors for cardiovascular diseases include non-modifiable (increasing age, family history) and modifiable (high blood pressure, high cholesterol, smoking, diabetes, obesity, physical inactivity) factors (Table 5). Increasing age is a key risk factor for heart disease, stroke, and congestive heart failure. About 86% of all heart disease deaths in Connecticut occur among those aged 65 and older (1999-2001 data). For men, major increases in heart disease mortality rates begin in the 35-to-39-year-old age group; for women, major increases in mortality begin at ages 55 to 59. About 92% of all stroke deaths and 96% of all congestive heart failure deaths in Connecticut occur among persons aged 65 and older (1999-2001 data).[36] A family history of heart disease and stroke increases one's risk of developing these diseases. A combination of inherited characteristics and behavioral patterns (similar dietary, smoking, and activity habits, for example) are thought to explain increased risk within families.[37, 38]

Lower socioeconomic position (SEP) is an important risk marker for cardiovascular disease (CVD). SEP is commonly measured by personal income, household income, or educational attainment level. Persons of lower SEP have higher CVD morbidity and mortality than do middle- or upper-income persons. Behavioral risk factors such as smoking, hypertension, and obesity are more prevalent in lower SEP persons and may explain some of the observed disparity;[39,40] however, other factors, like neighborhood socioeconomic environment, appear to have effects on individuals' risk for CVD.[41,42] Low-income neighborhood environments may contribute to increased CVD risk and poorer health outcomes because of such factors like poorer air quality, fewer food choices, and lower quality and/or lack of public services.[43] Lower-income persons tend to have less access to, and/or less effectively use, preventive health services that are important to the early detection and treatment of hypertension.[44] While low-socioeconomic

0579
09/15/08

position may be considered "modifiable" in the sense that people can move in and out of poverty during a lifetime or over generations, it is not usually within a given individual's control to change his or her social position or neighborhood environment.

Table 5. RISK FACTORS FOR CARDIOVASCULAR DISEASE

Modifiable Factors	Non-Modifiable Factors
• high blood pressure	• increasing age
• high cholesterol	• family history
• smoking	
• diabetes	
• obesity	
• physical inactivity	

Modifiable Risk Factors

Current Connecticut Behavioral Risk Factor Surveillance (BRFSS) data show that about one out of three Connecticut adults report having one or more modifiable risk factors for cardiovascular disease. Following are summaries of the five main risk factors (high blood pressure, high blood cholesterol, tobacco use, diabetes, and obesity) for coronary heart disease and stroke. Dyslipidemias had been traditionally regarded as a risk factor for CHD but not for cerebrovascular disease; however, several recent studies have established a direct relationship between increased serum lipids and stroke risk.[45]

High Blood Pressure

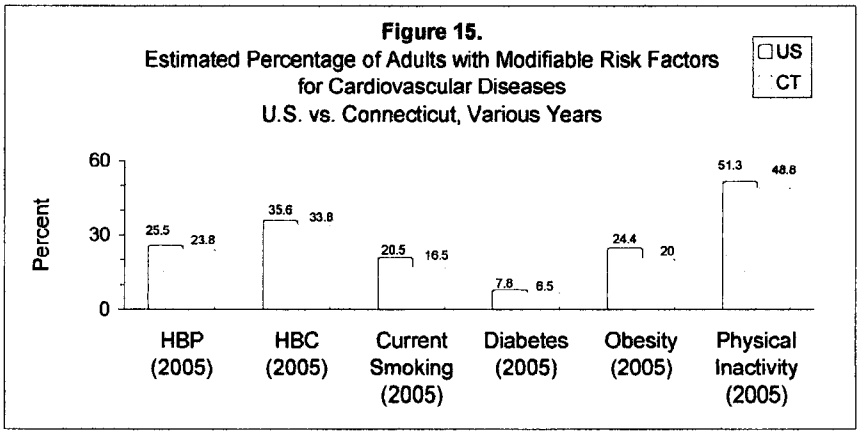
High blood pressure (HBP) is a major risk factor for heart attack and the most important modifiable risk factor for stroke. People with elevated blood pressure ($\geq$ 140mm Hg systolic / 90 mmHg diastolic) are 2 to 4 times more likely to develop CHD as are people with normal blood pressure.[46] About 26% of all stroke mortality is attributable to high blood pressure.[47] New federal guidelines classify normal blood pressure as below 120/80 mm Hg and readings from 120/80 Hg up to 140/90 mmHg as prehypertensive.[48]

Approximately 24% of Connecticut adults report that they have high blood pressure compared with about 25% of adults nationwide (Figure 15).[49] The risks for hypertension-related cardiovascular disease increase markedly with age, as does the prevalence of hypertension, and drug treatment for high blood pressure.[50] Black Connecticut adults experience high blood pressure more than White and Hispanic adults. About 36% of Black Connecticut adults report

0580
09/15/08

that they were told they had hypertension compared with 24% of White, and 14% of Hispanic adults in Connecticut (Figure 16).[51]

Figure 15.
Estimated Percentage of Adults with Modifiable Risk Factors for Cardiovascular Diseases
U.S. vs. Connecticut, Various Years



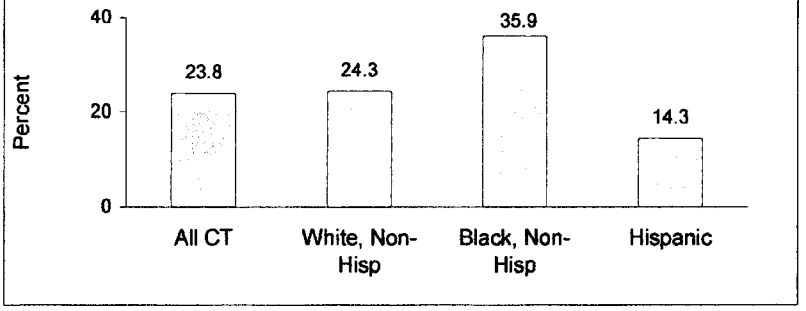


Figure 16.
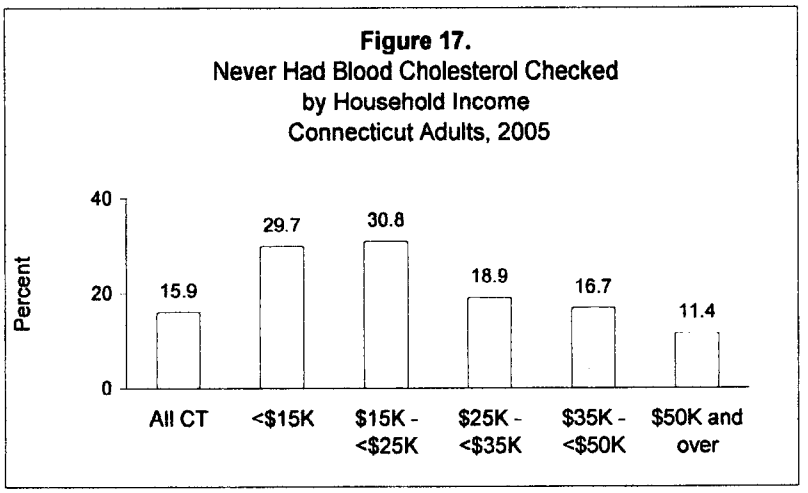
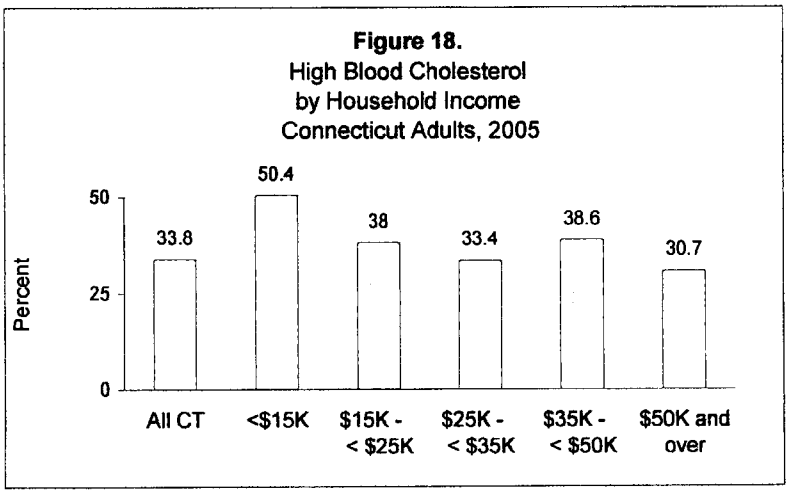
High Blood Pressure Prevalence Among Connecticut Adults by Race and Ethnicity, 2005



Source for Figures 15 and 16: Centers for Disease Control and Prevention, Behavioral Risk Factor Surveillance System, 2005.



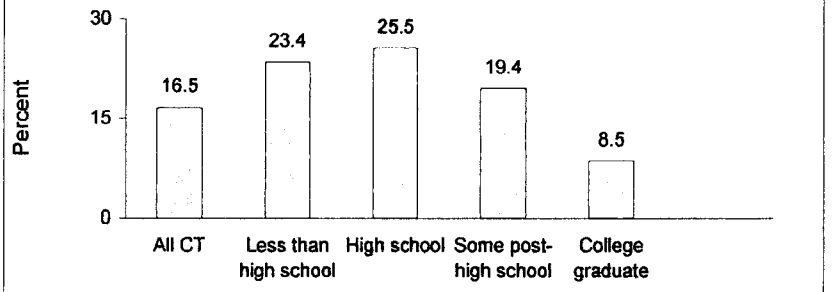
High Blood Cholesterol

High blood cholesterol (HBC) is considered a major risk factor for heart disease and a moderate risk factor for stroke. The Centers for Disease Control and Prevention estimates that more than 80% of people with high blood cholesterol do not have it under control. A 10% decrease in total blood cholesterol levels may reduce the incidence of coronary heart disease by as much as 30%. [52] Studies have found that stroke risk can be reduced with cholesterol-lowering medication among persons with higher cholesterol levels and persons with coronary artery disease.[53]

0581
09/15/08

Connecticut adults compare favorably to adults nationwide in terms of cholesterol screening and blood cholesterol levels. In 2005, 80% of Connecticut adults reported having had their blood cholesterol screened within the last five years compared with 73% of adults in the U.S.[54] About 34% of Connecticut adults were told they had high blood cholesterol (HBC) compared with about 36% of adults nationwide (Figure 15).[55] Lower-income Connecticut adults are more likely to report that they have never had their blood cholesterol checked compared with higher income adults (Figure 17). Among Connecticut adults who have had their cholesterol checked, lower-income residents are also more likely to report high blood cholesterol compared with higher-income adults in Connecticut (Figure 18).

Source for Figures 17 and 18: Centers for Disease Control and Prevention, Behavioral Risk Factor Surveillance System, 2005.



0582
09/15/08

Smoking

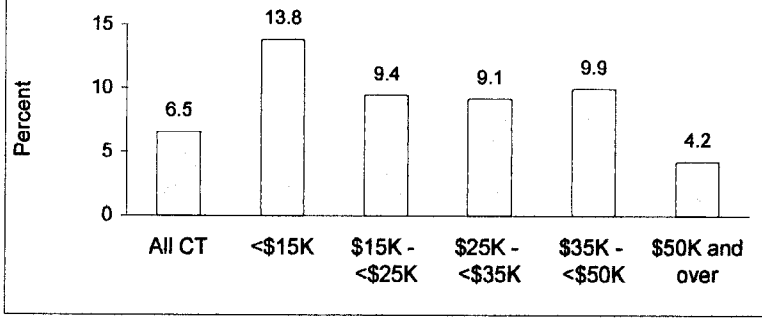
Cigarette smoking is a major modifiable risk factor for cardiovascular diseases. Smoking causes reduced blood vessel elasticity by increasing arterial wall stiffness. Smoking increases the risk of heart attack two-fold. Smokers have higher CHD mortality rates than non-smokers and their risk of death increases with greater number of cigarettes smoked. Current smokers have more than twice the risk of stroke compared with those who have never smoked.[56] Approximately 18% of strokes are attributable to current cigarette smoking.[57] People who stop smoking decrease their stroke risk and their risk of CHD mortality.[58]

In 2005, about 16% of Connecticut adults reported being current smokers compared with about 20% of adults nationwide (Figure 15). Connecticut adult smokers are more likely to be younger, with lower incomes, and less educated. For example, 31% of Connecticut adults 18 to 24 years old smoke compared with only 20% of those aged 45 to 54, and 7% of those aged 65 and older. About 30% of adults with household incomes under $15,000 smoke, compared with 14% of adults with household incomes of $50,000 or more. About 23% of adults with less than a high school education smoke compared with only about 8% of adults who graduated from college (Figure 19).[59]

Figure 19.
Current Smoking by Educational Attainment
Connecticut Adults, 2005

Source: Centers for Disease Control and Prevention, Behavioral Risk Factor Surveillance System, 2005.

0583
09/15/08



Diabetes

In recent years, diabetes has been recognized as a major risk factor for cardiovascular disease. Cardiovascular disease (CVD) is the primary cause of death for persons with diabetes, accounting for about 65% of mortality. Increased cardiovascular risk precedes the formal diagnosis of type 2 diabetes by many years. [60] Diabetic persons are 2 to 4 times more likely to develop coronary heart disease than the rest of the population and are at much greater risk of having a stroke.[61, 62] People with diabetes often have high blood pressure and high cholesterol and are overweight, increasing their risk for CVD even more. [63]

About 6.5% of Connecticut adults have been diagnosed with diabetes compared with almost 8% of adults nationwide (Figure 15).[64] Lower-income people are at higher risk of diabetes than are higher-income people. For example, approximately 14% of Connecticut adults with household incomes under $15,000 report having diabetes, compared with 4% of Connecticut adults with household incomes over $50,000 (Figure 20).[65]

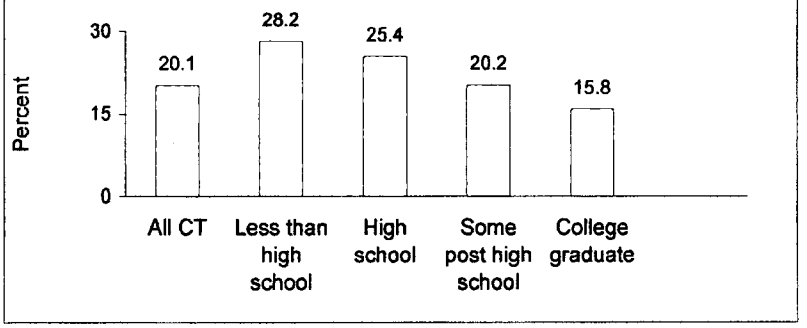
Diabetes self-management education is essential because improperly controlled diabetes can result in cardiovascular disease, kidney disease, blindness and loss of limb. It is, therefore, a particular concern that 52% of Connecticut adults with diabetes reported that they had never taken a course to manage the disease.[66]

Figure 20.
Diabetes Prevalence by Household Income
Connecticut Adults, 2005

Source: Centers for Disease Control and Prevention, Behavioral Risk Factor Surveillance System, 2005.

Obesity

Body mass index (BMI), or weight adjusted for height, is a widely used screening method for obesity. Medical guidelines identify normal/desirable weight as a BMI under 25, overweight as a BMI of 25 to 29.9, and obese as a BMI of 30 or more.[67] The prevalence of overweight and obesity has been increasing in the United States since the mid 1980s.[68] High calorie diets, along with less physical activity, in our society have contributed to the obesity epidemic.[69]



0584
09/15/08

Obesity is considered a metabolic disorder, which can be explained by a combination of hereditary and environmental factors. Obesity has been found to independently predict coronary atherosclerosis. Left ventricular hypertrophy, right heart changes and systemic hypertension are more common in those who are obese. While comorbidities relating obesity to coronary heart disease increase as BMI increases, body fat distribution is also an important factor.[70] For example, abdominal obesity places individuals at higher risk for health problems, including high blood pressure, high blood cholesterol, high triglycerides, diabetes, heart disease and stroke.[71] Obesity increases the risk of fatal and non-fatal stroke. Among females, increasing BMI is associated with increased risk of stroke. Among males, abdominal obesity, rather than BMI, is closely related to stroke risk.[72]

An estimated 20% of Connecticut adults are obese compared with about 24% of adults nationwide (Figure 15).[73] Approximately 38% of Connecticut adults are overweight, and 42% are normal or desired weight.[74] Adults with less education are more likely to be obese than adults with more education in Connecticut. For example, an estimated 28% of adults with less than a high school education are obese, compared with only 16% of college-educated Connecticut adults (Figure 21).[75] African American (non-Hispanic) females are more likely to be obese compared with White (non-Hispanic) and Hispanic females. An estimated 39% of African American adult females in Connecticut are obese, compared with 26% of Hispanic adult females, and 17% of White adult females (data not shown). There are no significant differences in obesity among Connecticut adult males by race or Hispanic ethnicity.[76]

Connecticut adults who are obese are significantly more likely to report that they are in poorer health compared with non-obese adults. Twenty percent of obese adults reported that they were in fair or poor health compared with about 10% of those who were overweight or of healthy weight (data not shown).[77]

Physical Inactivity

Physical inactivity and poor diet are associated with an increased risk of a number of chronic health conditions including cardiovascular disease, diabetes, some cancers, high blood pressure, overweight and obesity, back problems, and osteoporosis. [78, 79] Physical inactivity indirectly increases the risk of stroke because it is associated with high blood pressure.

The Centers for Disease Control and Prevention (CDC) and the American College of Sports Medicine (ACSM) recommend that all adults should engage in "at least 30 minutes of moderate-intensity physical activity on five or more days of the week." [80] Approximately 49% of Connecticut adults report having less than thirty minutes of moderate physical activity five or more days per week (Figure 22).

Physical inactivity increases with age. About 59% of Connecticut adults 65 and older do not meet the recommended CDC/ACSM activity levels compared with 34% of Connecticut adults aged 18 to 24 (data not shown). Lower-income adults are also more likely to be physically inactive compared with higher-income adults. About 61% of Connecticut adults with incomes of less than $15,000 per year are inactive compared with 43% of Connecticut adults earning $50,000 or more per year Figure 22).[81]

Source: Centers for Disease Control and Prevention, Behavioral Risk Factor Surveillance System, 2005.

Co-Prevalence of Cardiovascular Risk Factors

Coronary heart disease and stroke share a common set of risk factors that are usually found among those who develop one or both of these diseases. For example, research has shown that 84% of those having both diabetes and hypertension were also found to have dyslipidemia (abnormal lipid levels),[82] and that the relative risk of ischemic heart disease, stroke, and all-cause mortality increases linearly with the number of metabolic risk factors (overweight, high blood

0586
09/15/08

pressure, high fasting glucose, and high total cholesterol).[83] Approximately 52% of Connecticut adults report having 2 or more and 25% report having 3 or more modifiable risk factors for CVD.[84] The co-prevalence of risk factors contributes to the complexity of disease management.

Recognizing the Signs and Symptoms of Heart Attack and Stroke

The *Healthy People 2010* national objectives for both heart disease and stroke include increasing the proportion of persons who are aware of the early warning symptoms and signs of heart attack and stroke and the necessity of calling 911 when persons are suffering from either of these conditions.[85] Early recognition and calling 911 increase the likelihood of immediate emergency transport to the hospital and timely medical care that can reduce disability and death.

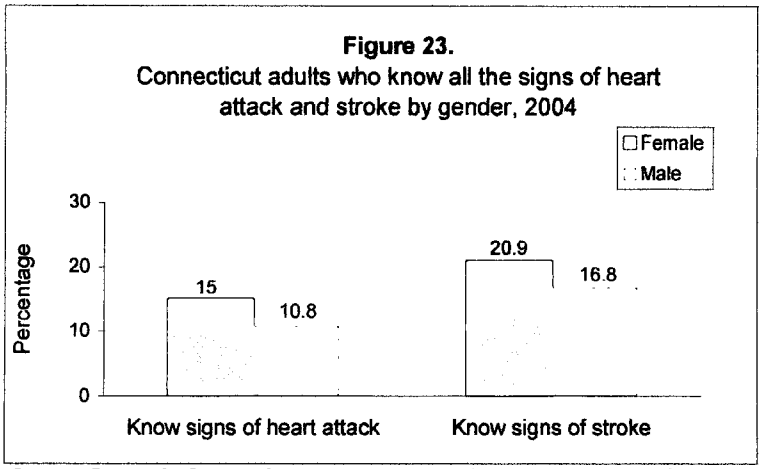

Table 6. WARNING SIGNS FOR HEART ATTACK AND STROKE

Heart Attack	Stroke
• Jaw, neck, back pain	• Severe headache with no known cause
• Lightheaded, faint	• Trouble seeing in one or both eyes
• Shortness of breath	• Trouble walking, dizziness, or loss of balance
• Arm or shoulder discomfort	• Confusion, trouble speaking
• Chest pain or discomfort	• Sudden numbness/weakness of face, arm, or leg

Source: Centers for Disease Control and Prevention, Behavioral Risk Factor Surveillance System, 2004.

The percentage of Connecticut adults who know all the warning signs and symptoms for heart attack and stroke tends to be very low. About 13% of Connecticut adults know all the proper heart attack signs and 19% know all the proper stroke signs. Women tend to be more knowledgeable than men about signs and symptoms of heart attack and stroke. About 15% of Connecticut females know all heart attack signs compared with about 11% of males ($p < .05$). About 21% of Connecticut females know all stroke signs compared with about 17% of males ($p < .001$) [Figure 23].

Access to Health Care

Access to health care is key to the prevention, treatment, and management of heart disease and stroke. People without health insurance are less likely than others to have a usual source of care, to receive preventive health care services, and appropriate medical management of chronic conditions. About 9% of Connecticut adults aged 18 and over do not have health insurance compared with almost 15% of adults nationwide. Hispanic adults in Connecticut are least likely to report having health insurance (about 31%), followed by Black adults (14%), and White adults (6%). Comparable national figures show that about 39% of Hispanic adults, 19% of Black adults, and 12% of White adults nationwide reported having no health insurance (Figure 24).[86] The health status of the entire Connecticut population is compromised when large numbers of residents are uninsured, and it imposes a significant additional financial burden on our state.

Targeting High-Risk Populations

The high co-prevalence of risk factors for cardiovascular disease indicates the need to address all these risk factors rather than each factor individually in public health interventions. A special emphasis needs to be placed on adults with diabetes, whose high percentages of high blood pressure, overweight and obesity increase their risk for developing cardiovascular disease. Second, screening for high blood pressure, high cholesterol, and overweight is necessary to address the high co-prevalence of these three factors. Third, smoking cessation, cholesterol and blood pressure control would greatly benefit those with multiple risk factors, especially for those with diabetes (Table 7).

0588
09/15/08

Table 7. TARGETING HIGH-RISK POPULATIONS

- Address multiple risk factors together
- Emphasize risk factor interventions among adults with diabetes
- Screen for high blood pressure, high cholesterol, and overweight
- Emphasize smoking cessation, blood cholesterol management, and blood pressure control

Black Connecticut residents have higher coronary heart disease death and premature mortality rates compared with White and Hispanic Connecticut residents. Black females have higher stroke death rates, and Black males and females have higher premature stroke mortality rates compared with the respective White and Hispanic populations. Black Connecticut residents have significantly higher rates of some important modifiable risk factors for cardiovascular diseases, such as high blood pressure, diabetes, and overweight/obesity (females only) compared with White and Hispanic Connecticut residents. Lower-income residents are also more likely to have higher rates of high blood pressure, high cholesterol, diabetes, current smoking, obesity, and physical inactivity compared with higher-income residents. Targeted public health interventions are warranted for all Connecticut residents with multiple risk factors, and special emphasis should address risk factor reduction among Black and lower-income Connecticut residents.

Appendix 1. Data Sources

Connecticut Vital Records Mortality Files

The Connecticut Vital Records Mortality Files are part of the state's vital statistics data base that contains records pertaining to deaths that occur within the state as well as deaths of Connecticut residents occurring in other states and Canada. Mortality statistics are compiled in accordance with the World Health Organization (WHO) regulations, which specify that deaths be classified by the current Manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death. Deaths for the 1989-1998 period included in this report are classified by the Ninth Revision of the International Classification of Diseases [ICD-9] (World Health Organization 1977). Deaths for the 1999-2002 period are classified by the Tenth Revision of the International Classification of Diseases [ICD-10] (World Health Organization 1992).

The race-ethnicity designation is typically based on report by next of kin, a funeral director, coroner, or other official. As such, the race-ethnicity designation based on observation may be reported incorrectly. Another potential source of error is the fact that death rates are calculated using two different sources of data – the death certificate for the numerator and the Census Bureau population estimates for the denominator. Errors in under- or overcounting populations by race and ethnicity will affect the death rates reported for these groups. Mortality data are reported using racial categories that exclude persons of Hispanic origin (White, non-Hispanic and Black, non-Hispanic) and by Hispanic ethnicity (Hispanics of any race). Death Registry data follow the National Center for Health Statistics guidelines for coding race and Hispanic ethnicity.

Behavioral Risk Factor Surveillance System

The Behavioral Risk Factor Surveillance System (BRFSS) survey is a state-based system of health surveys that generate information about health risk behaviors, clinical preventive practices, and health care access and use. The BRFSS, sponsored by the Centers for Disease Control and Prevention, is the world's largest telephone survey, and is conducted in all 50 states. It is an on-going random sample telephone survey of non-institutionalized adults, 18 years and older. Information from the survey is used to improve the health of people nationwide and in Connecticut. Racial and ethnic classifications are based on self-report and include White, non-Hispanic, Black, non-Hispanic, and Hispanic (including persons of any race). Other national and state-specific risk factor data and information regarding BRFSS methodology can be accessed on the CDC's BRFSS Web site at: http://www.cdc.gov/brfss/

Connecticut Hospital Discharge Abstract and Billing Data Base

The Connecticut Hospital Discharge Abstract and Billing Data Base is the source of inpatient hospitalization data. It is maintained by the Connecticut Office of Health Care Access, and it contains patient-level demographic, clinical, and billing data for all non-federal acute care hospitals in the state. In addition to age, gender, and town of residence, the demographic data elements include race and ethnicity. Based upon observation of the patient rather than self-reporting by the patient, race is designated as White, non-Hispanic and Black, non-Hispanic. Hispanic ethnicity includes persons of any race.
